BROOKLYN, N. Y.—At a meeting of the Board of Supervisors, held August 5, the question of building a tunnel, under Newtown Creek, from this city to Long Island City was discussed, and a motion to appoint a day on which all interested parties could be heard was carried.

IT is reported that M. H. Keefe, Helena, Mont., has the contract for cutting the Busk-Ivanhoe Tunnel on the Continental Divide of the Rocky Mountains, on the line of the Colorado Midland Railway, which, when completed, will be the third largest tunnel in the United States, and that the work is now likely to be pushed to an early finish. The Ingersoll-Sergeant Rock Drill Company, No. 10 Park Place, New York, will furnish the complete double outfit of tunneling machinery—boilers, air compressors and rock drills.

WHEELING, W. VA.—The following proposals for building a stone bridge over Wheeling Creek were opened by F. L. Hoge, City Engineer, July 21, 1890:

ITEMS.	BIDDERS.						
	Paige, Carey & Co., New York, N. Y.	Hallock Bros., Roetstown, O.	Harrold & Campbell, Beaver Falls, Pa.	B. B. Harris, Greensburgh, Ind.	J. Le Duke, Berea, O.	Jutte, Stratton & Foley, Pittsburg, Pa.	Jolly Bros., Pittsburg, Pa.
For each cubic yard of grading approaches, as specified	$0.75	$0.70	$0.40	$0.40	$.30	$0.60	$1.00
For each cubic yard of excavation in foundation pits for abutments, including the refilling and removal of same, as specified	1.00	1 00	1.25	.60	.75	1.50	1 80
For each cubic yard of excavation in foundation pits of wings, including the refilling and removal of the same, as specified	.40	.42	.60	.60	.90	1.50	1.80
For each cubic yard of excavation in foundation pits of abutments and wings removed over 300 feet, per 100 feet, as specified	.03	.03	.03	.20	.02	.02	.02
For each 1,000 feet of white oak plank used in drainage, per M., B. M., as specified	27 50	28.00	35.00	30.00	30.00	26.00	22.00
For each pound of wrought-iron spikes used in drainage and dowels in coping, tie rods, nuts and washers, used in spandrels, as specified	.05	.05	.05	.02$\frac{8}{10}$	.05	.03½	.06
For each pound of Steel I beams, wall plates and brackets, as specified	.05	.05	.04	.03$\frac{7}{10}$	.04½	.04	.06
For each lineal foot of vitrified clay pipe of 12 inches diameter, used in drainage, as specified	.30	.30	.75	.75	.38	.37½	.40
For each lineal foot of same, of 18 inches diameter, used in drainage, as specified	.35	.37½	1.25	.85	.65	.48	.65
For each lineal foot of same, of 24 inches diameter, used in drainage, as specified	.50	.55	2.00	1.37	1.20	.87	1.25
For each cubic yard of concrete (Portland cement) used as specified	7.50	7.40	9.00	9.00	6.50	7.36	9.50
For each cubic yard of concrete (American cement) used, as specified	5.50	5.50	7.00	6.15	5.00	6.00	8.00
For each cubic yard of masonry laid in the abutments in Portland cement mortar, as specified	12.25	12.25	12.50	12.95	14.00	11.00	11.50
For each cubic yard of masonry laid in abutments in American cement mortar, as specified	10.50	10.25	11.80	12.00	11.00	8.00	11.00
For each cubic yard of masonry used in arch sheeting, including centering and coating back of arch, as specified	16.00	15.00	16.50	*21.40 †16.75	27.00	27.07	33.50
For each cubic yard of masonry used in wings and external spandrels, as specified	8 00	8 00	9.00	12.00	11.50	12.50	11.50
For each cubic yard of masonry laid in arch backing, as specified	8.00	8 00	5.50	7 00	6.00	8.00	6.80
For each cubic yard of masonry used in retaining walls, as specified	8 00	8.00	6.80	9.00	6.00	9.00	11 50
For each cubic yard of masonry used in parapet walls, as specified	21.00	20.00	18 00	‡	30.00	27.07	15.00
For each cubic yard of brick masonry used in interior spandrels, as specified	10.00	10.00	8.50	10.20	8.00	13.60	9.30
For each cubic yard of granite (if used) for ring stones, as specified	50.00	52.00	....	40.00	38.00	55.00	55.00
For each lineal foot of Medina sandstone in curbing set, as specified	1.00	.98	.80	1.00	.65	.75	.75
For each square yard of flagging laid, as specified	2.00	2.05	2.25	2 80	2.00	3.00	1.60
For each square yard of brick paving laid, as specified	1.50	1.55	1.30	.85	1.25	1.50	1.35
For each insulated pole set, as specified	150.00	140.00	25.00	35.00	45.00	45 00	150.00
Estimated cost American cement in abutments	$104,386.00	$102,045.00	$110,106.00	$124,981.00	$123,364.00	$131,031.00	$143,814.00

* Berea, O., stone; † Frefort, O., stone. ‡B. B. Harris, Berea, O., stone, $21.00; Frefort, O., stone, $16.00, for each cubic yard of masonry used in parapet walls. Hallock Bros. bid withdrawn, and contract awarded to Paige, Carey & Co., of New York, who have commenced work.

PROPOSALS.

(Continued from page ii.)

STREET PAVING.

SEALED PROPOSALS WILL BE RECEIVED for furnishing the materials and laying about 4,750 square yards of **GRANITE BLOCK PAVING** at the office of the Board of Road Commissioners of the city of Waterbury, City Hall, until 2 P. M., August, 20, at which time and place they will be publicly opened and read.

All bids must be upon proper blanks and must be accompanied by a bond for $300, with satisfactory sureties, conditioned for the execution of the contract within five days after notice of its award.

Certified checks for $300, payable to the city of Waterbury, to be deposited with the Board of Road Commissioners, will be received in place of the above bond.

Specifications can be seen at the City Engineer's office, at which place blank forms of proposal can be obtained as well as further information.

By order of the Board of Road Commissioners.

F. W. WHITLOCK,
11 Acting City Engineer.

PROPOSALS.

Notice to Sewer Contractors.

SEALED PROPOSALS WILL BE RECEIVED up to TUESDAY, August 26, 2 o'clock P. M., at the office of the Board of Directors of the Street and Sewer Department, of the city of Wilmington, Delaware, for the construction of certain **SEWERS**, as follows: 5,715 feet of brick sewer, from 24 inches diameter to 2' 7" by 3' 10½", and 6,753 feet of terra cotta pipe, from 8 inches diameter to 20 inches diameter.

A certified check for $1,000, made payable to the order of the Board of Directors of the Street and Sewer Department, will be required of each bidder as a guarantee that the party or parties to whom the contract may be awarded will execute the same within five days after notice so to do has been sent to the address furnished by them.

The right to reject any or all bids is reserved.

Proposals must be sealed and addressed, "The Board of Directors of the Street and Sewer Department, Proposals for Building Certain Sewers."

Copies of the proposals, contract and specifications will be sent to those desiring them, or the same, together with the plans, can be seen at the office of

T. CHALKLEY HATTON,
12 Engineer in Charge of Sewers.

PROPOSALS
FOR
Key West Improvements.

OFFICE OF CITY CLERK,
KEY WEST, FLA., June 2, 1890.

SEALED PROPOSALS WILL BE RECEIVED by the City Clerk of KEY WEST, FLA., until 1st of September, 1890, for furnishing the necessary material and putting in an underground system of **SEWERAGE**; also for **GRADING** and **PAVING** the streets of said city and furnishing the material for same; also for furnishing and laying of water mains.

1st. All bids must be made upon the printed forms to be obtained from the City Clerk and inclosed in a sealed envelope, directed to the Board of City Commissioners, and marked on the outside of envelope, "Proposals for Key West Improvements."

2d. Each bid must be accompanied by a cash deposit or certified check of five hundred dollars, to be left in the hands of the City Clerk, subject to the conditions specified, as a guarantee of the good faith of the bidder.

3d. The city reserves the right to reject any and all bids.

4th. Bidders are requested to be present at the opening of the bids.

5th. Bidders are expected to bid separately on sewer system and material, on grading and paving of streets, and on furnishing and laying water mains.

6th. Plans and specifications can be seen at the office of the City Clerk, and at the office of Johnson & Flad, Consulting Engineers, Laclede Building, St. Louis, Mo.

WM. L. DELANEY,
8-10-12 City Clerk.

WHARF, Washington, D. C.—Proposals are wanted until September 2, for rebuilding Broad Street Wharf, at League Island. Address N. H. Farquhar, Chief of Bureau of Yards and Docks, as above.

AQUEDUCT, New York City.—Proposals are wanted until August 27, for building an auxiliary earth and masonry dam with gate house, etc., for reservoir D, near Craft's Station. Address John C. Sheehan, Secretary Aqueduct Commission, as above.

BUILDING, Ukiah, Cal.—Proposals are wanted, no date specified, for the erection of a $50,000 building here. Address Architects Copeland & Banks, 126 Kearney Street, San Francisco, Cal.

BUILDING, Hoquiam, Washington.—Proposals are wanted, no date specified, for the erection of a brick and stone building here, at an estimated cost of $25,000.

Madison and Hayne, br store and flats; cost, $15,000; o, B Mercel; a, W T Lesher.

Van Buren nr Laflin, livery stable; cost, $18,000; o, E Morse; a, same as above.

Washington boul nr Francisco, br and s dwell; cost, $13,000; o, S H Warner; a, Hetherington & Warner.

Forestville av nr 48th, s dwell; cost, $13,000; o, O F Lindman; a, F R Schock.

Belmont av nr Lake Shore, s dwell; cost, $16,000; o, Edw Gray; a, G W Maher.

154 bldgs costing less than $7,000 each.

DORR, MICH.—A $7,000 building will be erected here. Address A W Rush & Son, architects, as above.

DUQUOIN, ILL.—The Presbyterians will erect a church here.

GRAND RAPIDS, MICH.—Brick furniture factory building, also engine and boiler room, dry kilns, etc; cost, $20,000; o, Gunn Folding Bed Co; a, W G Robinson; b, not awarded.

College av nr Fountain st, fr residence; cost, $7,500; o, C C Philbrick; a, as above; b, not awarded.

MILWAUKEE, WIS.—Cor Astor and Brady sts, saloon and bowling alley; cost, $9,000; o, Pabst Brewing Co; a, Otto Strack; b, J Langenberger.

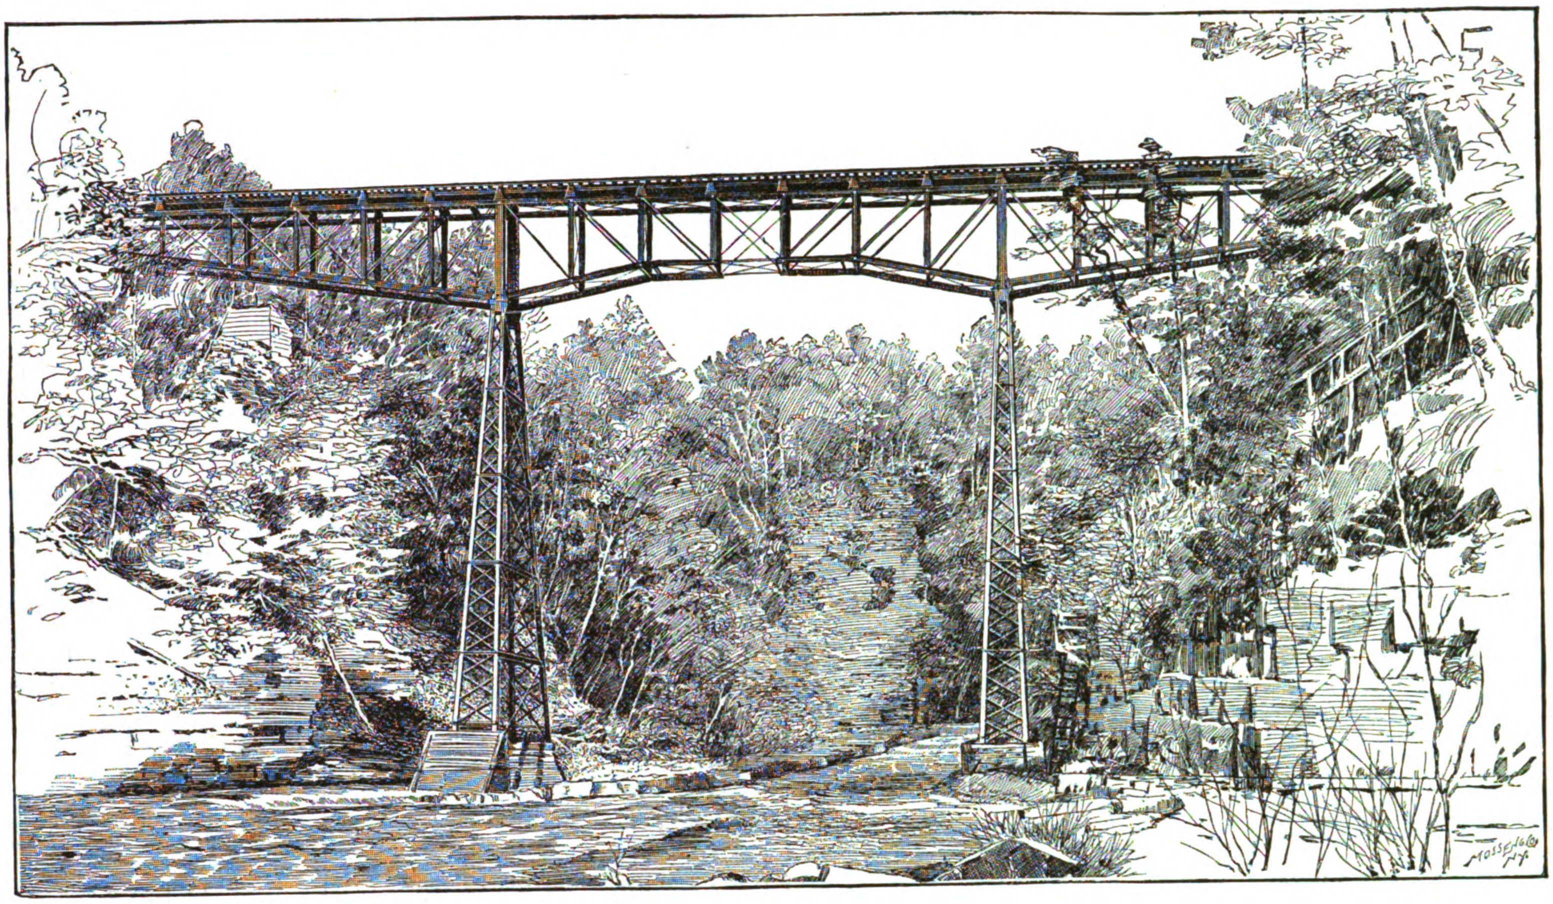
PHILADELPHIA, PA.—Cor 31st and Jefferson sts, brewery; o, Estate of J Mueller.

22d and Dickinson st, 30 fr dwells; o, John Devlin.

247 S 13th st, fr dwells; o, Charles P Nesbit.

43d st, n w cor Ogden, 25 fr dwells; o, J R Jordan.

THE BERLIN IRON BRIDGE CO., EAST BERLIN, CONN.



CANTILEVER BRIDGE,
DESIGNED AND BUILT
FOR THE K. & A. C. R. R. CO., AT KEESEVILLE, N. Y.

BUILDING INTELLIGENCE.

PLYMOUTH, MASS.—A brick block is to be erected at this place.

POTTSVILLE, PA.—Market st, 4-story br brewery; cost, $50.000; o, Chas Rettig; a, H C Wagner; b, S Auman.

PUEBLO, COL.—Plans have been prepared for the erection of a $16,000 business block. Address Architect G W Roe, 303 Central Block, as above.

SALT LAKE CITY, UTAH.—N Commercial st, 4-story br warehouse; cost, $25,000; o, B Roberts; a, Carrol & Rem.

SANTA ANA, CAL.—The C P Leonardt Portland Cement Company will erect a factory building here, at estimated cost of $125,000.

SHORT HILLS, N. J.—A casino is to be erected at this place, at an estimated cost of $20,000.

SIOUX FALLS, DAK.—2-story fr res; cost, $7,000; o, A P Abbott; a, G W Myers, Detroit, Mich; b, not let.

ST. LOUIS, MO.—Geyer and Jefferson avs, br power house; cost, $10,000; o, N D Ry Co; b, Ittner & Spore,

Delmar and Boyle avs, br dwell; cost, $7,000; o, P Y Tupper; b, W Silliman.

Washington and Sarah st, dwell; cost, $7,000; o, Mrs A L Beeding; b, T H Busey & Co.

S w cor Lindell and Vanderventer avs, br church; cost, $20,000; o, West End Chr Church; b sub let.

S e cor 6th and Locust sts, br office bldg; cost $80,000; o, St Louis R E and Inv Co; b, sub let.

Manchester rd and Rapin st, br store and dwell; cost, $7,700; o, E R Martin; b, J Ferguson.

28th and Chestnut sts, br church; cost, $33,000; o, African M E Church; b, Dan Evans.

The Heckel Hardware Co will erect a $50,000 store bldg.

BUILDING INTELLIGENCE.

SHREWSBURY, N. J.—A new town hall is to be erected at this place.

SIOUX CITY, IOWA.—Cor Pierce and 6th sts, corn palace; cost, $20,000; o, Corn Palace Co; a, J P Brown; b, Iverson & Johnson.

Second st, bet Court and Virginia, br and s warehouse; cost, $30,000; o, H H Wilkins; a, E Leak; b, not let.

SOUTH BETHLEHEM, PA.—Cor Seneca and Freytag, br and shingle res; cost, $9,000; o, W E Cox; a, A W Leh; b, no contract let.

ST. PAUL, MINN.—Farrar & Howes have filed with Building Inspector Johnson their plans for a 3-story brick and stone tenement row of 5 dwellings to be constructed on Summit av near Dale st, and cost $45,000.

The plans of the Merchants' National Bank building, to be put up at the corner of Fifth and Jackson sts, at an expense of $100,000, are also in the hands of Mr Johnson. The permit for this will be issued very soon.

The Young Men's Christian Association has applied for a permit for the new building on 10th st near Minnesota. It is to be 4-story stone and brick, to cost $90,000. The contracts have not been let yet.

Iglehart near St Albans, 2-story fr dwell; cost, $12,000; o, J E Williams.

5th, 4th and Wabasha, 3-story arcade bldg; cost, $250,000; o, Thomas Lowry.

Hill st, electric plant, power house; cost, $15,000; o, City Railway Co.

Jackson cor 5th, 3-story st and br bank building; cost, $100,000; o, Mercantile Nat Bank.

Summit nr Dale, 3-story br and st block; cost, $45,000; o, Farrer & Holmes.

Robert cor 5th, 7-story st and br building; cost, $250,000; o, Manhattan Co.

TUSKEGEE, ALA.—A $10,000 building will be erected here. Address Professor Fonville, as above.

BUILDING INTELLIGENCE.

URBANA, O.—A school building will be erected here, at a cost of about $16,000. Address Architects Williams & Otter, Dayton, O.

VALPARAISO, IND.—A $10,000 church will be erected here. For details address Claus Specht, as above.

WEST SUPERIOR, WIS.—A $10,000 dwelling will be erected here. Address E E Basten, as above.

WORCESTER, MASS.—Pleasant, br block; cost, $30,000; o, R C Taylor; a, Cutting & Forbush.

WASHINGTON, D. C.—201 3d st, 3-story br bldg; cost, $7,500; o, G P Zushost; a, A P Clark; b, C Gessford.

3313 O st, 3-story br bldg; cost, $8,500; o, F T Brookes: a, same as above.

Cor 19th and F sts, 2-story br bldg; cost, $18,000; o, A L Phillips; a, R T Fleming.

12th st, extended 3-story br bldg; cost, $7,500; o, Farnham & Chappel.

3d st bet L and N Y avs, 2-story br bldg; cost, $16,000; o, J L Locket; a, C T S Brent.

1215 F st, 4-story br bldg; cost, $30,000-o, M W Beveridge; a, J G Hill; b, Emmerst & Moody.

400–10 12th st, 6 2-story br bldgs; cost, $7,000; o, C Gessford; a, same as above.

301-9 Spruce st, 12 2-story br bldgs; cost, $36,000; o and b, W Y Lewis; a, N T Haller.

614 S st, 3-story br bldg; cost, $10,000; o, G T Wade; a, A P Clark; b, P Hepburn.

636 E Capitol st, 3-story br bldg; cost, $10,000; o, P N Dwyer; a, same as above.

2019 O st, 1406 Hopkins st, 2 3-story br bldgs; cost, $8,,000; o, L Dolliline; a, same as above.

Florida av, 5 2-story br bldgs; cost, $7,000; o, L M Saunders; a, C Federline.

1500 11th st, 3-story br bldg; cost, $8,000; o, R L Warring; a, same as above.

BUILDING INTELLIGENCE.

109–34 Col st, 13 2-story br bldgs; cost, $23,400; o and a, same as above.

210–20 C st, 3 2-story br bldgs; cost, $12,000; o, J J Clark; a, Isaac Beers.

1611 K st, 3 story br bldg; cost, $14,000; o, Rev J McKim; a, Harvy L Page; b, Addison & Larcombe.

1609 K st, 3-story br bldg; cost, $15,000; o and b, Addison & Larcomb; a, Harvey L Page.

319–23 5th st, 3 2-story br bldgs; cost, $10,000; o, T Y Shannon; a, W F Kirby & Bro.

1321–23 32d st, 2 3-story br bldgs; cost, $15,000; o, G W King; a, A R Grimm; b, R W Darby.

241 permits less than $7,000 in value.

BUILDINGS.—There is nothing over $7,000 in value to report at the following places: Ogdensburg, N. Y.; Montclair, N. J.; Charleston, S. C.; San Antonio, Tex.; Harrisburg, Pa.; Geneva, N. Y.; Galveston, Tex.; Wilkesbarre, Pa.; Dayton, O.; Binghamton, N. Y.; Poughkeepsie, N. Y.; Wheeling, W. Va.; Canton, O.; Youngstown, O.; Topeka, Kan.; Clinton, Iowa; Springfield, O.

WOLFF (A. R., M. E.) THE WINDMILL AS A PRIME MOVER. Comprehending everything of value relating to Windmills, their Use, Design, Construction, etc. With many fine illustrations. 8vo, cl.... ....$3 00

ADDRESS, BOOK DEPARTMENT,
THE ENGINEERING & BUILDING RECORD,
277 PEARL STREET, NEW YORK.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22. NUMBER 11. | PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.

NEW YORK, AUGUST 16, 1890.
LONDON, AUGUST 30, 1890.

SINGLE COPIES, TEN CENTS. Subscription, $4.00 per year in advance, post paid. | IN AMERICA.
Subscription, 25*s*. per annum in advance, post paid | IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.

25*s*. in GREAT BRITAIN. Other Foreign Countries $6.

Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $6; China, Japan, Sandwich Islands, Mexico and Cuba, $6; South America, $5.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

NEWARK'S WATER-WORKS *VERSUS* PASSAIC'S SEWERS.

THE very full abstract given on another page of the points at issue in the controversy between the cities of Newark and Passaic regarding the discharge of the latter's sewage into the Passaic River will be read with much interest by all who have to do with the problems of water supply or sewage disposal as related to fresh water navigable tidal streams.

The reasons for the legal distinction, as laid down by the Chancellor, between the rights of riparian owners on navigable tidal and navigable non-tidal streams are not very obvious to the lay mind. In the former case the riparian owner is said to have no special right in the stream except the contingent one of accretion, while his riparian neighbor further up the river where the tide has ceased to flow, but where vessels still can come, owns the land under water to the middle of the stream, and can make any use of the water that will not interfere with its use by others or the right of navigation. The most probable explanation that presents itself is that the lawmakers may have assumed that tidal water must be salt, and, therefore, unfit for use, and that the fall of the tidal portion of a river was necessarily too slight to afford any power, and, therefore, did not confer upon riparian owners on tidal streams a right that seemed to have no value. Salt water is, however, often used for street sprinkling, for which purpose it is better than fresh, and tide mills are not uncommon. If any distinction is to be made between the rights of riparian owners on the banks of the same stream, it would certainly seem to be more reasonable to let that distinction be determined by the character of the adjacent water rather than by its tidal change of level. Such a rule applied to the present case would give the city of Newark a standing in court, for the lack of which she seems just now to be suffering a serious injustice.

As to the effect of tidal action in delaying the downward flow of sewage, Mr. Wurtz would seem to be seriously astray in his conclusions, since, as the effect of the natural current of the river is to make the ebb flow longer than the flood, and the effect of the ebb is to accelerate the natural flow of the river, it would follow that the effect of the tide is to bring down the greater portion of the daily discharge of sewage at a rate more rapid than that of the natural current, instead of obliging the greater part of it to traverse a much greater distance before reaching a given point below, as Mr. Wurtz believes will be the case. It must be noted, too, that greater distance does not necessarily imply greater time, which is the essential thing in the aerial oxidation of which Mr. Wurtz speaks.

Some instructive figures as to the effect of the use of the Passaic River water on public health are to be found in an editorial in our issue of June 18, 1887, by which it appears that for the seven years ending in 1881, in which Jersey City and Hoboken were both supplied with Passaic River water, the total death rate of Hoboken exceeded that of Jersey City by 7 per cent., and the death rate from zymotic diseases (for 1880 and 1881) exceeded that of Jersey City by 22 per cent., while from 1882 to 1886 inclusive, after Hoboken had changed her source of water supply to the Hackensack River, the conditions were reversed, and the total death rate of Hoboken was about 1⅓ per cent. less than that of Jersey City, while that for zymotic diseases was 9 per cent. less. It is easy from these figures to conclude that the sooner Newark can avail herself of the proposed new water supply the less sickness and death she will have.

If Passaic were wise she would think twice before inflicting her sewage on her down-stream neighbor, even if the courts allow her to do so, since just above her is the large city of Paterson, and when all of her sewage comes to be poured into the river Passaic can make no remonstrance, and her beautiful stream will in course of time become practically an open sewer, to be perhaps purified at last, as has had to be done in similar cases in England, by the enforced construction of disposal works, whose cost will be much greater than if they had been planned for in the first place.

It pays to be neighborly even for cities.

THE RIVER AND HARBOR BILL AND THE ATTITUDE OF THE NEW YORK NEWSPAPERS.

THE New York daily papers are doing the business interests of the city and those of the whole country an injury by their protests against appropriations for the improvement and development of internal watercourses. This has been going on for years, and, as Senator Miller remarked, while the New York papers protest New York harbor is unimproved. The appropriations for the rest of the country have continued, however, although on two occasions the force of demagoguery was great enough to procure vetoes, in consequence of which a great many works necessary to the development of the country had to be suspended.

This steady opposition to all improvements not immediately adjacent to New York leads the editors of other localities to ask if the opposition is not due to the influence of railroads, or in favor of Canadian canal projects. Under the influence of this feeling a western paper writes: "There is no longer any immovable reason why we should permit the intensely selfish aggrandizement of New York City to stand between the West and Liverpool." The effect of this feeling, which is possibly more general than is imagined, is shown by the action of the Senate Committee in cutting out of the appropriations the one for continuing the cut between the Harlem and the Spuyten Duyvil, an improvement of great value to New York City. One of the New York papers protesting against such action says, "Where so much money is virtually thrown away by the River and Harbor bill," etc.; but though its editor has been challenged to mention any work of magnitude on which the money has been expended to better advantage, he has not responded.

Though not even the entrance to Duluth Harbor, which was cut through a ridge 6 or 7 feet above the surface of the lake, had less depth of water than the cut through Dykeman's Meadow, between the Harlem River and Spuyten Duyvil Creek, these papers are continually inveighing against appropriations for creeks and waterways on which they assert there is no traffic, when they know there can be no traffic on any route until facilities are offered for it. They know that, without a lock, commerce through the Sault Ste. Marie would still be impossible, while the tonnage passing through that canal in seven-twelfths of a year is equal to seven-elevenths of the tonnage entering New York in the whole year. They also know that 10,000,000 more tons pass Detroit during the same seven months than enter and clear at all the seacoast ports of the United States, and that most of this is due to River and Harbor Bills.

Can any one wonder that there is a general prejudice against a city, which, judging from the nearly unanimous tone of its press, has been steadily opposed to the appropriations which has set this mighty stream of commerce in motion, a stream which by raising the price of agricultural products to the producer and decreasing their cost to the consumer enlarges the purchasing power of the money of every one in this country? Nor is the poverty of the West conducive to the wealth of New York and the seaboard generally.

BETTER COUNTRY ROADS.

AT a meeting at Pittsburg last week, of the Pennsylvania State Road Commission, Mr. James B. Powell, referring to the poor system of roads in Pennsylvania, said:

> "Poor roads are compelling farmers to give up agriculture and go to the large cities and towns. One-third of every year a farmer in Pennsylvania is bound up at his home with mud. If your commission commends any radical change the farmers will be scared by the prospect of increased taxation. Do not think of too costly roads. Ohio has five pikes costing only from $3,000 to $12,000. It has been said your commission thinks of having stone roads made. With your 70,000 miles of road in Pennsylvania I consider that an impracticable scheme. Erie County, with its fine gravel and sand—what need has she for stone? You should study the demands of localities. Some roads that are much traveled, like those in the neighborhood of a town, should be improved at a cost of about $3,000 per mile. Other roads ought not to be at more than $250 per mile.
>
> "Every road in the county ought to be named or numbered so that a stranger may know where he is. As soon as practicable all road taxes should be paid in cash. Educate the people up to this. Show them poor roads depress the value of their farms, and that as long as men work out their taxes it is impossible to have good roads.
>
> "I favor State aid for road improvements because towns are increasing in population, and they would pay much of the tax."

Another member of the commission said:

> "I would like to see all road taxes paid in money. State aid is needed to make roads good. The State is great and can afford it. Each county should appoint commissioners, and money should be distributed according to road mileage. I think convict labor on roads would be a good thing. To see criminals with a ball and chain attached, working on the public roads, would be a very wholesome lesson to young people, which would be an impression for good that no other mode of punishment would convey."

Among the practical suggestions made at the meeting was that of Col. J. J. Carter. He favored the establishment of a bureau of State roads, to be connected with the executive department of the State Government, and presided over by a State Engineer or Surveyor General, to be appointed by the Governor. He also favors a road supervisor for each county, to be elected by the people at the same time and for the same period as members of the Assembly are elected—no one to be eligible unless an educated and professional engineer; also a board of road overseers for each township, borough or city, not less than three nor more than five, to be elected by popular vote on the plan of minority representation in each district; the supervisors to appoint a roadmaster, who shall be an engineer by practice, for each district.

A GREYTOWN correspondent of the New York *Tribune*, writing on the Nicaragua Canal, says that the estimated length is 180 miles, and by means of lakes and rivers there are 120 miles clear. There are, consequently, only 60 miles of cut to be made, 13 miles on the Pacific side and 47 miles on the Atlantic side. There are to be six locks, and the depth of the water is to be 30 feet the entire length of the canal. It will take 28 hours for a vessel to pass through, and the rate is to be $2.50 per ton. The canal company now expects to complete the work in seven years.

THE prevailing scarcity of water at Jersey City, N. J., is ascribed to the lack of conduit capacity between the Belleville and distributing reservoirs.

BOOKS ON HOSPITAL DESIGN AND CONSTRUCTION.

IN response to an inquiry from Messrs. Maury & Dodd architects, Louisville, Ky., for information, in book form, concerning hospital design and construction, we repeat that the literature on this subject is voluminous, so that there is much room for selection. Volumes VII., VIII., IX., X., XI., XII., XIII. and XV. of THE ENGINEERING AND BUILDING RECORD contain interesting plans and valuable data concerning the planning and designing of hospitals, upwards of twenty notable hospitals being illustrated and described.

The following are well known books on the subject of hospital construction:

Johns Hopkins Hospital; Hospital Plans; Five Essays by Drs. Billings, Folsom, Jones, Morris and Smith, 8vo; New York; William Wood & Co.; 1875.

Das Städtische Allgemeine Krankenhaus, in Friedrichshain zu Berlin; von Gropins & Schmeiden; Berlin; 1876.

Galton, D.; Report Descriptive of Herbert Hospital at Woolwich; 4to; London; 1865.

Nightingale, F.; Notes on Hospitals; 3d edition; 4to; London; 1863.

Husson, A.; Étude sur les hopitaux; 4to; Paris; 1862.

Monat & Snell; Hospital Construction and Management; 4to; London; 1883–84.

Billings; Ventilation and Heating; New York; 8vo; published by THE ENGINEERING AND BUILDING RECORD; 1884.

Esse, C. H.; Die Krankenhäuser; Ihre Einrichtung und Verwaltung; Berlin; 1868.

D. Galton; An address on the general principles which should be observed in the construction of hospitals, with the discussion which took place thereon; London; 1869.

Oppert, F.; Hospitals, Infirmaries and Dispensaries; Their construction, interior arrangement and management, with descriptions of existing institutions and 74 illustrations; London; 1883.

WATER METERS AT DETROIT.

ACCORDING to the Detroit, Mich., *Free Press*, the saving in the consumption of water which has been effected by the introduction of the meter system at that city has enabled the Water Board to postpone the installation of an additional pumping engine. For this there would have been an imperative demand by this time if the waste of water had not been checked.

A committee was appointed at the last meeting in July, of the Water Board, to look into the matter of reducing the meter rates on water. They reported, at a meeting last week, in favor of keeping the rate on the first 5,000 cubic feet consumed each month as it has been in the past, one cent per 100 gallons. After the first 5,000 cubic feet they recommended that the rate be reduced from three-quarters to one-half cent. This reduction is made possible by the great saving that has resulted from the first year's use of the meters. The report of the committee was adopted, the reduction to take effect on the first of the present month. The report of the secretary showed over 700 meters now in use, and more being added continually.

THE CHESAPEAKE AND OHIO CANAL.

THE fourth report of Henry G. Winship and Victor Cushwa, receivers of the District of Columbia portion of the Chesapeake and Ohio Canal, has been filed with the Supreme Court of the District. The receivers state that a civil engineer familiar with canal business has been employed to go over the entire length of the canal and make measurements and estimates. He reports that the cost of repairs will be $165,955, which, when added to $39,095, required for certain lock gates, etc., needed for the effective operation of the canal, will make about $200,000, which will be the total cost of putting the canal in full navigable order from the Potomac at Cumberland to Rock Creek at Georgetown. They advise that in case this work is undertaken and completed the canal shall be apportioned into nine sections, each section to be under the control of a section boss at $900 per annum, with carpenters, lock keepers, inspectors, harbor masters, collectors, clerks, trimmers, laborers, etc., in all 180 employees, at salaries from $200 to $900 per annum, all under a general superintendent at $3,000 per annum, the whole salaries being $58,740.90. To this is to be added the cost of material needed to keep the canal in running order, extra work in annual repairs and contingencies, making the total annual cost of operating the canal $80,000. The receivers exclude from their estimate of the cost of running the canal the cost of operating the Cumberland coal wharf and the outlet lock of the Potomac Lock and Dock Company above Georgetown. They do not think the canal should pay the charges for telephone service. On the basis of repairing the canal for $200,000 and operating it for $80,000 per annum, they claim that the canal would be profitable, for the presidents of the coal companies have assured the Maryland receivers that 450,000 tons of coal will be sent over the canal each year. The receivers think that with this output of coal and other certain business an annual income of $200,000 can be realized by the canal.

"With the surplus earnings of $120,000 per annum over the operating expenses," continues the report, "your receivers believe that with wise and proper business management the Chesapeake and Ohio Canal can be relieved of its present floating indebtedness, its bonded indebtedness of 1878, together with the interest and the indebtedness to be incurred in the repair of the canal for business operations and other known indebtedness subsequent to the bonded indebtedness of 1844, in about ten years, and that then the claims of the other bondholders could be liquidated."

COMING MEETINGS.

THE American Association for the Advancement of Science will hold its 39th meeting at Indianapolis, Ind., beginning with the council meeting on August 19. At the opening general session of the association on August 20, in the Capitol, President Mendenhall, Superintendent of the U. S. Coast Survey, will resign the chair to his successor, Professor Goodale, of Harvard College, and in the evening will deliver his annual address, to be followed by a reception.

Besides the regular sessions, which will continue until the evening of August 26, the Local Committee has arranged excursions to Terre Haute, Lafayette, the Mammoth Cave, the Shades of Death, and the Natural Gas Region around Kokomo.

Special rates have been secured for transportation and at the hotels. The Permanent Secretary, Prof. F. W. Putnam, can be addressed at the Denison Hotel, Indianapolis, Ind. The officers of the Local Committee are Dr. George W. Sloan, Chairman; Noble C. Butler, Treasurer, and Alfred F. Potts, Secretary.

AMERICAN MACHINERY ABROAD.

THE Ingersoll-Sergeant Rock Drill Company, of New York, has just received an order, from the contractors engaged in removing the iron gates of the Danube, for a large plant of submarine drilling apparatus. Mr. Bessier, a German engineer, recently visited this country in the interests of the work on the Danube. He investigated American methods thoroughly, with the result mentioned. The work extends for 20 miles along the Danube River, and will cost about $5,000,000. The removal of these obstructions has been attempted many times; the earliest attempt dating back to the times of the Roman emperors.

PERSONAL.

COL. B. S. CHURCH, of New York, was recently engaged in going over the project of the Ocmulgee Canal Co., of Macon, Ga., for bringing water to that city from the Ocmulgee river through a 10-mile canal.

W. H. EDWARDS, architect, recently located in Harriman, Tenn., would like to receive some building trade circulars, catalogues, and office samples of building specialties.

K. E. HILGARD, M. Am. Soc. C. E., formerly Principal Assistant Engineer in charge of Fourth Street extension C. & O. R. R., of Cincinnati, sailed for Europe on Wednesday, August 13, on steamer "Nordland," to be absent for several months.

HENRY C. MEYER, Editor and Proprietor of THE ENGINEERING AND BUILDING RECORD, returned from Europe on the steamer "Etruria" August 10, and is now in the Adirondack Mountains.

LETTER FROM ENGLAND.

(Regular Correspondence.)

LONDON, August 1, 1890.

THE question of acquiring the rights of the water companies is being extensively agitated both by the London County Council and the various vestries, and a meeting composed of delegates from the various vestries has recently been held with this view. No apparent result has been arrived at, the chief thing blocking the way apparently being the fact that the London County Council are taking steps to try and get legislation on the point, and the vestries are, of course, anxious to take advantage of the Council's experience in pressing through such action. The resolution was, however, come to that a standing committee should be appointed to prepare notices of a draft bill and to take such other steps as might be necessary for promoting the bill in Parliament for the purchase of water companies' undertakings.

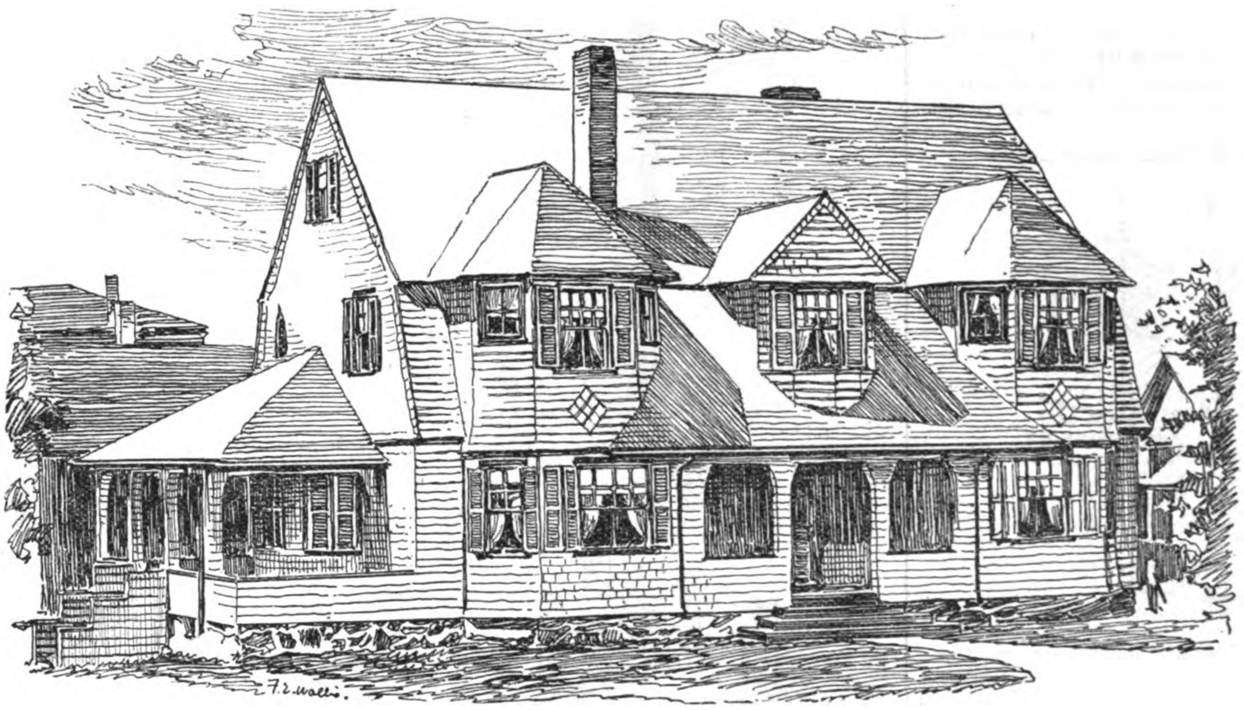
Referring to the special Water Committee promoted by the London County Council, and now being held in the Guildhall in connection with the proposed legislation for acquiring water service, it is interesting to note that the water companies, who were all invited to send delegates, have replied with unanimity, refusing to take advantage of the offer.

The St. Pancras Vestry has decided to provide electric light for public service and for private supply on its own responsibility, and the Electricity Committee of the vestry has recommended the acceptance of tenders amounting to £50,946 ($244,540 80) to carry out the work. The installation apparently will provide 10,000 incandescent lights and 90 arc lamps. Professor Robinson is the engineer for the vestry, and Dr. Hopkinson, of the Institute of Electric Engineers, and Mr. Preece, of the Post Office, having been consulted on the undertaking, express their concurrence and belief that it should be profitable to the ratepayers generally.

A system of dredging which has found great favor at Tilbury Docks, the invention of Mr. Tideman, the Engineer of the East and West India Docks, is now undergoing trial at Southsea. The principle is that of using water jets delivered through twelve nozzles in a frame lowered to the bed of the channel. The application of this principle is in connection simply with the silt deposited by incoming tides. It is stated that whereas the dredging necessary at Tilbury, consequent upon the deposit by the incoming tide in the various basins alongside the ships' hulks, had been £1,200 ($5,760) per week, with this system of water jet it had been reduced to £273 ($1,310.40) per week.

The question of height of buildings in the city is under discussion before the Lords' Committee, who are considering a bill relating to the powers of the London County Council. The proposal is that no building shall be erected to a greater height than 70 feet without the consent of the Council under penalty for contravention. Mr. Balfour, Surveyor to the Duke of Westminster, supported the clause generally so far as stopping monstrosities was concerned, but at the same time would like to see the limit fixed at 100 feet, pointing out specially that it was of advantage that workingmen's dwellings should be allowed to go to a considerable height with a view to obtaining as much room as possible. Captain Shaw, Chief of the Fire Brigade, also attended before the committee, and was of opinion that having regard to the condition of the city, the narrowness of the streets and the crowding of warehouses, the proposed extended powers to the London County Council to increase the cubical contents of warehouses would be fraught with considerable danger unless there was a protecting clause that such enlargement should only be consented to subject to the report of the Superintending Architect and of himself (Captain Shaw). The captain's view was that 60 feet should be the limit. It was of course not for him to advocate the increase of height, inasmuch as his point of view is purely the "fire" point. The committee finally decided that 70 feet was insufficient and that 90 feet was to be recommended.

ACCORDING to a Racine, Wis., account the Wind Lake Canal, one of the most gigantic drainage enterprises ever undertaken in the Northwest and the largest ever attempted in the State, is now completed. Less than two years have been necessary to do the work whereby fifteen miles of canal has been dug and a vast tract of country drained. The land reclaimed, which has hitherto been valueless, is now worth in the neighborhood of $500,000.



RESIDENCE OF DR. F. D. STACKPOLE, YORK HARBOR.—WHEELWRIGHT & HAVEN, ARCHITECTS, BOSTON, MASS.

THE NEW CROTON AQUEDUCT.

THE recent formal opening of the New Croton Aqueduct was somewhat hastened to relieve the urgent demand for additional water supply in this city, and to test certain portions of the construction by subjecting it to actual working conditions before final approval.

It was decided to make a preliminary trial which should inaugurate and test its operation, fill the city storage reservoir in Central Park, and flush out the conduits.

After accomplishing this the aqueduct was to be again emptied, and final inspection and work done before regular service was commenced. Accordingly, after the required satisfactory service, the head gates at Croton Dam were shut at 9 A. M., August 6, so that no more water could enter the aqueduct except by seepage, &c.

The upper portions of the conduit were duly emptied by the gravity flow down to the hydraulic grade line, and at 10 P. M., Aug. 7, the "blow offs" at shafts 25 and 26 were opened and emptied all the submerged part (that below the hydraulic grade), except the section between shafts 24 and 25, which comprises the tunnel under the Harlem River.

The engine at shaft 25 was started at 9 A. M. August 9, and at 7.30 A. M. August 11 had emptied the tunnel.

The final preparations for executing the remaining repairs were commenced on August 11, in the aqueduct between shafts 18 and 19.

The original defects of construction of the aqueduct have been described in these columns, and consisted largely in the omission of backing that was specified to fill all spaces between the masonry and the irregular surface of the tunnel and shaft excavations. Most of these defects have been remedied by piercing the walls and filling the cavities with grout under pressure or by cutting out and replacing sections of the masonry and building the required backing in the cavities. Between shafts 18 and 19 there still remain open spaces over the top only of the aqueduct (which is here a horse-shoe shaped tunnel 10'6"x10'6" inside with arched brick walls about 15 inches thick).

As there can be no hydraulic upward pressure on this part of the aqueduct, it was decided to allow its preliminary use without waiting to put in the overhead filling necessary to protect the brickwork from falling stone, etc. While the aqueduct is emptied the scaffold shown, Figs. 1

and 2, will be erected and afterwards a stream of water 2 or 3 feet deep in the bottom of the aqueduct will deliver a daily supply of 25 to 40 million gallons for city use without in any way obstructing the repairs. Figure 1 is a cross section of the aqueduct, and Fig. 2 is a section at Z Z, Fig. 1, and shows several bents of the scaffold that is 3,000 feet long.

Near shaft 18 an opening has been made through the top of the aqueduct into an open cut through which materials are delivered to the car C that runs on track T and distributes them to holes A A, etc., through which the cavities are filled, each cross beam is firmly secured by the wedges D D driven tight against the side walls of the aqueduct.

A little more grout will be forced through the walls from this platform and some finishing touches will be given to the shafts from adjustable circular platforms suspended from the top, but it is expected that the work will be completed in six weeks, and it is interesting from its simplicity and the arrangements for conducting it while the aqueduct is in operation.

Figure 12 shows a general diagram of the tunnel which is pumped out through shaft 25. The tunnel was originally intended to be driven from C but was depressed, as shown, to avoid the rock seam D.

Figure 3 is a vertical section through the shaft at W W, Fig. 7. Figure 7 is a section at Z Z, Figs. 3, 4 and 5. Figures 4, 5 and 6 are vertical sections at Y Y, X X, and V V, respectively, Fig. 7.

A is the aqueduct and B the pump shaft, both lined with brick walls, backed up with solid rubble masonry to the surface of the rock excavation. The pump shaft has a cast-iron lining, *i*, Fig. 9. O is the aqueduct to New York and Q is the tunnel aqueduct under the river. Communication between shafts A and B is controlled by a gate S, operated by shaft N. As the hydraulic grade line is above the tops of these shafts the arches I I, etc., are built to resist the upward pressure; they have manholes closed by iron covers H H, etc. F is a 36-inch supply pipe; G is a 12-inch drain; J is a 20-inch drain; K and L are 48-inch blow-off pipes emptying into the river.

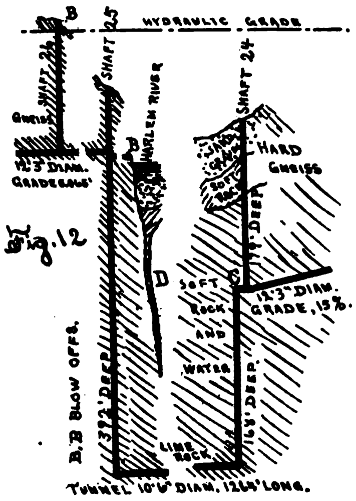


Fig. 12

As the tunnel is likely to be rarely emptied the usual form of pump would be unsuitable and subject to deterioration from disuse and the buckets E E were provided instead for dipping the water out. Each bucket has a capacity of 1,350 gallons and is attached to a steel wire cable passing over sheave C and wound on drum D, that is driven by a reversing engine. The buckets E counterbalance each other, one ascending full while the other descends empty. When the ascending bucket reaches the proper height it is announced by an indicator and the ringing of a bell, an attendant reverses the engine and the other bucket is drawn up, and so on.

While the buckets always rise to a standard height, they have continually to be given a little more descent until the water level is lowered to the bottom of the shaft. This is effected by having one of the drums fixed upon the shaft, while the other is loose and bolted to the first. By releasing these bolts, while holding the loose drum with the brake, the engine is driven in one or the other direction until the proper amount of rope has been fed out, when the bolts are refastened. This whole operation takes about three minutes.

An average of three bucketfuls per minute was dipped out of the shaft, and the contents of shafts and tunnel, amounting to about 3,000,000 gallons, was dipped out in 46½ hours.

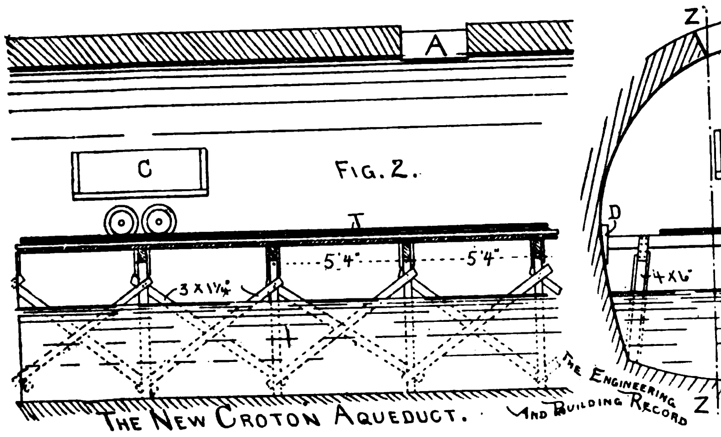

Fig. 1. Fig. 2.

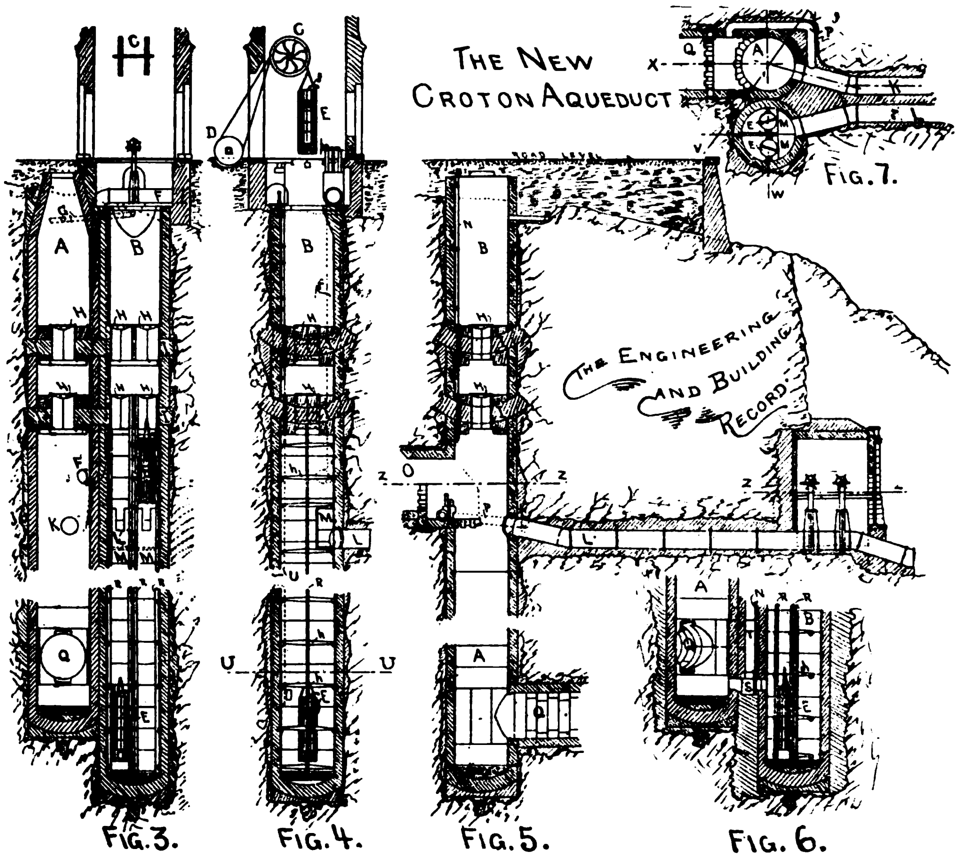

Fig. 3. Fig. 4. Fig. 5. Fig. 6. Fig. 7.

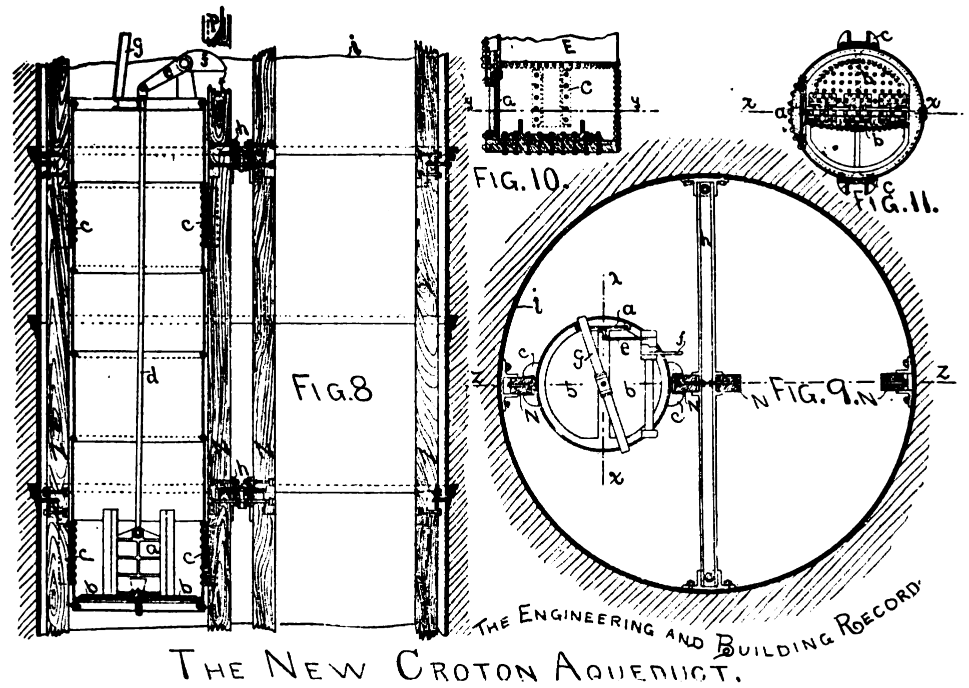

Fig. 8. Fig. 9. Fig. 10. Fig. 11.

THE NEW CROTON AQUEDUCT.

Figure 9 is an enlarged cross section of the shaft at U U, Fig. 4.

Figure 8 is a section at *x x*, Fig. 9.

Figure 10 is a section at *z z*, Fig. 9, of part of the bucket.

Figure 11 is a section at *y y*, Fig. 10, and shows one of the valves *b* open instead of closed, as elsewhere represented.

The reference letters in these figures have the same significance as in Figs. 3, 4, 5, 6 and 7, except that the same pieces are designated here by N N, etc., and there by R R, etc.

When the descending bucket strikes the surface of the water the butterfly valves *b b* open upwards and the bucket fills; when the bucket rises these valves close and retain its contents. N N, etc. (R R, etc., Figs. 3, 4 and 6), are yellow pine guides engaged by the lugs *c c*. When the bucket reaches the required height the latch *f* is tripped by the fixed cam *p*, and, operating the lever *e* and rod *d*, raises gate *a* and allows the water to be discharged into catch basin M (Figs. 3, 4 and 7), and thence through blow-off L.

After the tunnel had been emptied it was inspected by the engineers and found satisfactory. Some mud, sand and loose cement was found in the bottom, where it had been deposited by drainage from other portions of the aqueduct. After this is cleaned out the water will be re-admitted.

THE ROCHESTER, N. Y., WATER-WORKS.

THE potable water supply for the city of Rochester, N. Y., is taken from Hemlock Lake, a natural mountain lake in Livingston County, about 30 miles south of Rochester, 900 feet above sea level and about 380 feet above the level of the city. The area of the water-shed is about 43 square miles.

The city is supplied by a gravity system, the water flowing first into an impounding reservoir at Rush, eight miles south of Rochester, and from there into the Mt. Hope reservoir within the city limits. From this the water is distributed through the city. The capacity of the two reservoirs is 88,091,908 gallons, and the daily available supply is about 9,000,000 gallons, the estimated population of Rochester being 135,000. The total length of conduit is about 30 miles.

For fire purposes in the business center of the city water is supplied by a Holly direct pressure pumping plant, the water being taken from the Genesee River. Power for this plant is furnished by turbine water-wheels, though auxiliary steam power is provided for. The daily capacity of the plant is 7,000,000 gallons. The highest point supplied in the city is 625 feet above sea level and the lowest 137 feet. The pressure in the mains for domestic or potable supply is 40 pounds per square inch, and in the mains of the Holly system 100 pounds per square inch. On December 31, 1889, the figures for mileage of mains, number of hydrants, etc., were:

Miles of mains (potable)	201.281
Miles of mains (Holly)	13.83
Total	215.111
Hydrants	2,043
Watering troughs	43
Fountains	2
Water meters	2,060
Taps	23,146

The water-works are city property. The care and maintenance of the water supply, as well as of the highways and the problem of fire protection, are in the hands of an Executive Board composed of three members, one of whom is elected at each annual spring charter election for a term of three years. This Board has sole power to let all contracts to be made by the city in pursuance of ordinances passed by the city's Common Council, except such as are directed by law to be made otherwise, and has the supervision and control of all work ordered by the Common Council. The bonds for the construction of the water-works were issued under Act Chapter 387, Laws of 1872, and the original fourteen wards of the city, with an aggregate acreage of 4,840 acres were jointly liable. In 1874 two new wards, the Fifteenth and Sixteenth, were annexed to the corporation. Together they have an area of 5,809 acres, making the total area within city limits 10,649. A law was passed which provided that whenever a majority of the taxpayers on a street within the annexed territory shall petition for the extension of water mains or of lamps upon such street, for their benefit, the taxable property and residents upon said street shall become jointly liable to assessment. This petition is presented to the Common Council by the alderman of the ward in which the street is situated. This is true for any ward in the city, but a majority of the owners' names is insisted on in the case of the before-mentioned annexed territory.

If the petition is reported on favorably it is sent to the Executive Board who submits it to the City Assessors for official action as to its being a majority petition, and on its return it is filed for consideration. The various streets mentioned in the petition are personally examined and notes made of their conditions and surroundings, size of distribution mains determined on; estimates of cost of construction are prepared by the Engineer's Department, and a list is made which is considered by a Water-Works Committee of the Common Council, the Executive Board and the Chief Engineer of Water-Works. This committee determine upon what portions presented are in most pressing need of water, and fix upon the amount that will be required to be raised by tax levy for water pipe extension and report to Common Council.

The quantity of pipe and specials required for extensions and current repairs is made up. Notices of letting are published, and pipe contracts let in the usual manner. Public bids are also invited for unloading and distributing water-works materials for the season. The streets under consideration are then surveyed, levels run, grades established, and maps and profiles made (always in duplicate) of the work to be done. The different streets are then grouped in the most advantageous manner as to location, etc.; a letting sheet is prepared, and the groups are published in the official paper for a period of ten days prior to letting. During the three days immediately prior to letting an exhibit is made in the construction office of the water-works of the maps, profiles, if any, where extra cover is required over pipe in view of future reduction in grade, together with said letting sheet, setting forth the items of work embraced in the several groups. Proposal sheets are furnished each contractor. Sealed proposals are handed in to the Clerk of the Board, and the contract is generally let to the lowest bidder. The Board, however, reserves the right to reject any or all bids, etc.

The awards being made, the contracts drawn up, the work is carefully staked out by map; the work of trenching commenced, and an inspector appointed who sees that the proper depths are made to allow for 4½ foot cover; that the pipes are laid in true grades and alignment; that blocks and wedges are properly placed, and the specification amount of lead obtained. When the work of laying pipe has been completed, and joints are made up, hydrants and stop-gates set, etc., notice is given to the engineering department. Measurements of the pipe are then made with a steel tape, two men handling the tape and a third keeping a record, noting, among other things, the condition of the soil, depth of rock, gas pipes, etc., etc. About 59 miles of distribution mains were laid under contract at the time of the building of the works from the lake, and the work was completed October 1, 1876. Since that time the remainder has been put down; the yearly mileage varying according to requirements.

When the year's work is ended the amount and character of mains, etc., laid are noted alphabetically as to streets and embodied in a table. The amount of pipe removed is arranged in another table. Similar tables are arranged for recording the hydrants and stop-gates. The field notes are copied from the small field book into a large record book, in which everything is noted exactly as it occurred in making the measurements. These record books are kept on file.

The record maps are made on sheets of Whatman's cold pressed paper—double elephant, 3'2"x2'1½" outside; inside border, 3'x1'10½"; heavily backed by cloth with leather-bound edges. A scale of 40 feet to the inch is used, the sizes of the different pipes being represented by the following uniform signs.

Emerald green	4"	cast-iron	(light)	24"	cast-iron	(heavy)
French blue	6"	"	"	12"	"	"
Scarlet lake	8"	"	"	16"	"	"
Chrome yellow	10"	"	"	20"	"	"

Wrought iron pipes are shown in burnt sienna, with sizes marked on.

In these maps, the Domestic system is in full lines and the Holly system in broken lines. All Domestic stop-gates and hydrants are designated by blue circles and all Holly stop-gates by red circles.

Every special fitting is shown; streets are colored on respective sides, madder brown and sienna; lettering, uniform; main streets, heavy; side streets, scrip.

A pipe yard, connected with the water-works system, is located on the Erie Canal. Different sizes of pipe are there kept, together with a full line of specials, hydrants, stop-gates, lead, and all material entering into repairs of an extensive system. The various articles are charged to the pipe yard in a book kept for the purpose. Orders are made on the yard and the official in charge endorses the weight on the back and returns it to the engineer's office where it is credited to the pipe yard in a ledger. The lead used in calking pipe joints is obtained from the city and the amount is deducted in the monthly and final estimates. At the end of the season a general inventory is taken, a balance is struck, all material received is accounted for, and what scrap remains is sold.

The city employs a full force of men, calkers, tappers, plumbers, etc., known as the Repair Force. It is in charge of a superintendent of repairs who has a separate building connected by telephone with the office of the Executive Board. The Repair Force is constantly employed in the various duties common to all large distribution systems. They frequently lay large mains where immediate necessity requires it, and make all cut-outs for automatic service, large services, supply of factories, tenement houses, etc.

A brief reference to the Holly system pump-house and machinery will here prove interesting. The lot on which the pump-house is located is known as the south part of lot No. 5, of the Griffith Tract, located on Brown's Race. It has a frontage of 50 feet on the Race and extends back to the Genesee River. There are five water rights connected with the property, embracing about five-eightieths or one-sixth of the water of the Race. The location is eminently judicious, as it is situated but a short distance from the head of the Race, so that in time of low water and in case of emergency, such as a large conflagration, a free draught upon the whole body of water in the Race can be made.

The flume which conveys the water to the rear of the building is located on the south side of the building, its entrance at the Race being guarded by an iron rack or grating, whose bars are about four inches apart, which serves to exclude the larger floating bodies. At the wall separating the engine and boiler rooms, another rack with the bars only one inch apart is placed, by which the water is thoroughly screened and all bodies, of a size sufficient to cause injury to the wheels removed. Behind this second rack is a bulkhead having three large cast-iron vertical gates, each three feet wide and four feet high, by the operation of which the water may be admitted into or excluded from the remainder of the building. Between the flume wall and the boiler foundation is an arched culvert, 3½ feet wide and 6 feet high, the end at the Race being closed up with a solid wall 5 feet thick, beneath which and wholly below the bottom of the Race a large wrought-iron pipe 2 feet in diameter passes. The other end of the culvert is open towards the several suction pits. An opening 2 feet in diameter into this culvert near the bottom of the flume and regulated by a slide gate, allows the water in the flume ahead of the stop-gates to enter into this culvert and thence into the suction pits for the pumps, as well as into the above-mentioned wrought-iron pipe, which is then, however, closed off by a valve across the race. Behind the large wrought-iron tube in the rear of the building, which conveys the water from the flume above to the turbines below, is another bulkhead, with a large sliding gate, and behind this and the north flume wall all the pumps take suction.

A 24-inch wrought-iron pipe runs from the most southern race to the reservoir under the pump-house. This will furnish water to the pumps when Brown's Race is drawn off for any purpose, and may even be used to drive one turbine if required. In case the water should be drawn from both races at the same time, provision is made by which water from the 20 inch Hemlock Lake main may be forced into the 24-inch supply main and furnished to the pump-house for pumping back into the Holly mains, so that three distinct sources of supply of water for the Holly works are accessible.

The machinery consists of three distinct parts. The first embraces four combined steam piston engines, with cylinders 16 inches in diameter and 27 inches stroke, having variable expansion gear, and arranged so as to permit working either condensing or non-condensing. To these four engines four double-acting pumps, 10 inches in diameter and 20 inches stroke, are attached direct. The pumps and engines may, however, be readily uncoupled. Any one of the engines with its corresponding pump may also be quickly detached from the remainder of the set. The four engines with their pumps are arranged on two sides of a substantial arched frame of cast iron, supporting at its top the crank shaft, which carries a large fly-wheel, a gear wheel and the eccentrics. The two cranks at the ends of this shaft are at right angles to each other; and as two engines are coupled to one crank pin, one piston of this pair will be at the middle and the other at the beginning or end of its stroke, and hence it follows that in one revolution of the fly-wheel there will be eight successive discharges of four double-acting pumps, imparting a practically steady pressure and uniform flow of water in the pipes.

The second part of the machinery consists of a rotary steam engine placed in front of the above set, operating two rotary pumps for fire streams. The piston engines may also be made to operate one or both of the rotary pumps, by means of gear wheels, without the aid of the rotary engines.

The third part is the water set, which consists of eight double-acting pumps, arranged in two sets, each having four cylinders 9 inches in diameter and 24 inches stroke, mounted upon heavy cast-iron arched frames similar to the steam set; and, as in the latter, a pair of pumps are coupled together upon one crank pin on each side of the two frames. These two frames are isolated, but the machinery of the one may be connected to that of the other by means of a movable section of shafting, so that the power applied to the one will drive the other. The crank rod of each pump may be uncoupled so that any one cylinder may be isolated, and as in the case of the steam set, the four pumps of each of the two water sets are so connected to the cranks that there will be eight successive discharges of the water during one revolution of the crank shaft. The power used is derived from two turbines working under a head of about 90 feet. The shafts of these turbines extend continuously from the wheels to the frames, where they terminate each with a small bevel gear wheel, working into another of much greater diameter. The shaft supporting this latter wheel also carries a small toothed wheel, which, in turn, plays into the teeth of another large and heavy gear wheel fixed to the crank shaft, that imparts the motion and power to the pumps. These several transformations are rendered necessary in order to reduce the great speed of the turbines.

Steam is furnished by three tubular boilers, any one of which may be used separately, or all of them together. These boilers are each 5 feet in diameter, 16 feet long. Holly's hydrostatic pressure gauges or regulators, of which there are two, one for the steam and one for the water set, regulate the amount of steam to be supplied to the engines or the amount of water for driving the turbines, for a given pressure upon the mains, by means of an automatic mechanism, cutting off or increasing the supply independently of the engineer in charge, besides giving a signal upon a gong when an extra demand for water occurs, as in case of a large fire. There is, besides, a water safety valve in the building to prevent any rise of water pressure in the mains above a certain point.

It is estimated that the four combined steam engines will develop 300 horse-power and the rotary engine 150. The pumping capacity is guaranteed to be no less than 3,000,000 gallons in twenty-four hours, while that of the water set is to be no less than 4,000,000 gallons in twenty-four hours. The power of the turbines is estimated at 250 horse-power. The wheels are of the tangential class, 26 inches in diameter, and were built by Messrs. Stout, Mills & Temple, of Dayton, O. The flume or penstock is a wrought-iron tube 4½ feet in diameter, made of ¼-inch plates. Its lower end rests on a solid pier of masonry and has a 4-inch outlet valve through which it can be emptied.

The cost of the pump-house, land and water rights, cost of pipe and laying, and cost of hydrants and gates was about $350,000. For this sum a 7,000,000-gallon daily supply was obtained. It is thought that from no other source and in no other way could the city be furnished with so much water for anything like that sum. As a result of this construction the daily supply of the city is practically double what it would have been without it, and that, as already stated, for a smaller sum than it could otherwise have been obtained. For the purposes for which it was designed to be used, the river water is as efficient as water from any other source would be.

The present Executive Board of Rochester consists of Julius Armbruster, Chairman, term expires in 1891; William W. Barnard, term expires in 1893; George W. Aldridge, term expires in 1892; Thos. H. Neville, Clerk. George W. Rafter, is Assistant Engineer in charge of additional water supply and Acting Chief Engineer. The Construction Department consists of W. N. Radenhurst, Assistant Engineer in Charge; George A. Hotchkin, Assistant Engineer; Thomas H. Rogers, Draughtsman; F. M. Hills, Leveler; D. H. Westbury, Jr., Rodman. There are during the season three pipe inspectors, one pipe distributor and one man in charge of pipe yard. Daniel O'Neil is Superintendent of Repairs.

There is telephone communication between Hemlock Lake and the various points along the line of conduit—viz.: Richmond Mills, Honeoye Falls, Rush Reservoir and Mount Hope Reservoir. The telephone line was completed in the fall of 1877 and was one of the earliest put up.

ARIZONA WATER STORAGE.

PLANS for irrigating the arid lands of Arizona are, at present, attracting considerable attention.

The smaller streams of Arizona, says the Phœnix, Ariz. *Republican*, are all of one class, running fullest in the spring and almost failing in the summer. Those that run into the plains sink in the sands, and are lost for the major portion of the year. The question naturally arises, Why not store the winter water in suitable reservoirs, to be spread on the thirsty lands at the time of the drought?

This proposition has been appreciated, as is shown by the location of dam sites for water storage purposes in many parts of the territory. The Florence Canal Company has just finished an extensive reservoir in Pinal County to assist in the irrigation of the lands adjacent to the Casa Grande.

Among the projected reservoirs that have been located for the improvement of the lands lying below one of the most important is that upon New River, about thirty miles northwest of Phœnix. It is situated where New River debouches on the plain. The projectors are John King and W. C. Collier, who have been quietly working on the enterprise for years.

The dam will need to be nearly half a mile in length, 320 feet in thickness on the bedrock, 90 feet broad on top and 75 feet high. Hydraulic lime for the manufacture of cement, limestone and other rock for the construction of the dam are at hand in abundance, and can be cheaply quarried. Estimates from civil engineers of repute fix the cost of the work at less than $300,000. With the height of dam proposed the water would cover an area of eight by four miles, there being but little slope to the valley above. The supply of water from the spring freshets of the river is deemed ample, but as a precaution levels have been run to Hudson Creek, Castle Creek and the Agua Fria, and it has been demonstrated that it is practicable to divert at low cost the waters of those streams into the reservoir.

The Agua Fria, at the point tapped, flows the year round. All danger of overflow can be avoided, as a natural spillway exists at the proper height two miles back from the dam, conducting the water over a low bridge into the valley of the Agua Fria.

The land sought to be irrigated is really a continuation of this valley, and embraces over 75,000 acres of excellent soil. Many claims have already been filed in expectation of the benefits of the dam.

About eight miles farther to the west of this dam site and over a ridge is the location of a similar enterprise of fully equal magnitude. It is the property of the Agua Fria Water and Land Company, composed of L. H. Orme, J. P. Orme, J. D. Monihon, N. O. Murphy and William Hancock, all of Phœnix. The dam is to be situated at the narrow gorge of the Agua Fria, 300 yards above the Frog Tanks Hotel. The walls of the canyon at this point are but 300 feet apart to the height of seventy-five feet, and above this gradually retreat from the stream. The proposed dam is to be 175 feet high, with an ample width and a length on top of about 1,000 feet. It will not be difficult of construction. All rock and lime needed can be obtained right at hand.

A dam of the dimensions stated will back the water up stream a distance of ten miles with a depth at the mouth of Castle Creek of 125 feet. At a point two miles above the dam the reservoir will be three and one-half miles in width, besides extending for some distance up Castle and Humbug Creeks. The capacity of the reservoir is estimated at 40,000,000,000 cubic feet of water. This amount will supply for twelve months a canal carrying 40,000 miner's inches of water, and allow for an evaporation of 25 per cent. The natural flow of the Agua Fria will more than supply this amount every year.

The main canal will be taken from the river on the east side, about one and one-half miles below the Frog Tanks Station. It will run along the slope of the river bottom for a distance, emerging on the plain three miles below the Tanks. The land to be irrigated comprises about 75,000 acres. It is of excellent quality, especially adapted to the growth of citrus fruits.

THE entire cost of the Washington Bridge, New York, up to this time, exclusive of office expenses, has been $2,673,601.67, to which is to be added the office expenses, legal costs paid, more land purchased, and the work of grading and terracing completed.

THE patent suit of the Eclipse Radiator Company, of Chicago, Ill., against the makers of the Elite radiator, for infringement on its patent for an ornamental radiator, which has been in the courts for the past two years, has just been decided in favor of the plaintiff.

GARBAGE DESTRUCTION AT ST. LOUIS.

THE promoters of the measure authorizing the Mayor and Health Commissioner to enter into a contract for the disposal of the slop, offal, garbage and animal matter of the city by the Merz process, will begin the erection of two plants immediately upon the approval of their contract. According to the St. Louis *Republic*, the contract must be let before the 1st of September, and the contractors will be required to commence destroying the garbage within four months from that date. The recent three-years' contract for the removal of the garbage was so framed that the contractor can be required to deliver the slop and garbage at the works where they are to be destroyed. The contract for the disposal of the garbage will be entered into for a period of not less than ten years. At the expiration of that time the city has the privilege of purchasing the entire plant at a valuation to be fixed by arbitrators. It is now claimed that the works will cost $113,000. The exact location of the two houses will be determined by the contractors. The ordinance specifies that one shall be in the northern and the other in the southern part of the city.

The cost of the introduction of this system for the destruction of the garbage cannot be estimated beforehand. It is understood that the owners of the Merz patent-right for St. Louis will not bid above $2 a ton for the destruction of the slop and garbage. The amount of garbage collected has been variously estimated. Thirty tons a day is given as a fair figure. At that rate it will cost the city about $22,000 a year to dispose of the garbage and about an equal amount to collect it. The collection, removal and destruction of garbage and slop will cost about $42,000 a year. Then the ordinance provides for the appointment by the Mayor of a garbage inspector, whose duty it shall be to inspect the city for the purpose of determining whether all the slops and garbage are properly collected. Then the inspector is authorized to appoint a competent weigher, whose duty it shall be to see that the garbage is weighed correctly.

The report was sent out from Detroit recently that the Board of Health of that city had condemned their Merz works as a nuisance and ordered them removed. The works to be put up in St. Louis, however, will, it is said, be an improvement on the Detroit plant.

HARLEM RIVER IMPROVEMENT.

THE fact that the item of $350,000 for the improvement of the Harlem River has been stricken from the River and Harbor bill by the Senate Committee has induced Comptroller Myers, of N.Y., to write a long letter to Senator William P. Frye, Chairman of the Senate Committee on Commerce. The Comptroller describes the relations of the United States and the State and city of New York in the matter as follows:

"*First.*—Relying on the good faith of the Government of the United States to carry out this work, the Legislature of the State of New York authorized proceedings to take forcibly from private owners the necessary lands for it, and to compel riparian owners to pay for these lands and the expenses of acquiring them. Such proceedings have been taken, the riparian owners have been assessed the sum of $225,639.91, and the title to the lands so acquired by the city has been transferred to the United States. This assessment has been chiefly paid, and the amount unpaid by owners has been advanced by the Treasury of the city of New York.

"*Second.*—The city of New York has for this improvement ceded to the United States $109\frac{225}{1000}$ acres of land of great value.

"*Third.*—The United States Government has entered upon this work, and has already expended or contracted for the expenditure of $400,000 toward it; it is already well advanced, and the riparian ownership has for several years been adapting itself to the lines of the improvement, the plans of which have been approved by the United States Engineers.

"From the above it will be observed that the faith of the United States, of the State of New York, and that of the city of New York are pledged to the execution of this work, and that the property owners who have been heavily assessed and otherwise burdened by expenses and losses are entitled to have this work completed. For more than 20 years the subject of the improvement of the Harlem River has been before the public. It has been thoroughly discussed in all its bearings, and the work has received the sanction of the ablest engineers and approval of the whole community. The careful examination by the United States Government Engineers has resulted in the expenditure of a large amount of money for comprehensive plans, soundings, etc., the work has been undertaken and is well under way, then it is now suddenly assailed in its last stage of progress by unfriendly influences, and the most deeply regrettable delay ensues.

"I will not enlarge upon the great value of this work to the commerce of this city and of the Western and Eastern States further than to remind you that it will provide a necessary basin at the seaboard terminal of the only water channel of communication between the Atlantic Ocean and the great area bordering upon the lakes. When completed there will be a saving of over 20 miles of intricate, slow, and dangerous navigation down the North River, around the Battery, and up the East River for vessels coming through the Erie Canal and down the North River bound for the Eastern States, and for a considerable portion of the city of Brooklyn.

"The faith of the United States is pledged to the completion of the work, and the necessities of the railroad travel and traffic crossing the river already provided for by the United States Engineers may, with entire propriety and safety, be left to the municipal and State authorities. In my best judgment the speedy completion of the work should be at once assured by an adequate appropriation, and appreciating thoroughly the great interest you have always shown in the commerce of New York, I beg to respectfully bespeak your most valuable influence and efforts to procure the same."

COST OF ELECTRIC STREET LIGHTS.

IN discussing the matter of electric street lighting at Milwaukee, Wis., President Wall, of the Badger Illuminating Company, furnished the following statement of the prices paid for electric street lights, of nominal 2,000 candle-power, by 32 cities, the contracts being the latest ones awarded, and calling for all-night service:

NOMINAL 2,000 CANDLE POWER.

Place.	Term of Contract.	No. of Lamps.	Price per Lamp per Year.
Rochester, N. Y.	5 years	1,200	$105.00
Buffalo, N. Y.	3 years	1,246	146.00
Syracuse, N. Y.	3 years	300	146.00
Albany, N. Y.	6 years	480	182.50

Providence, R. I.	....	500	160.00

The low contract of Rochester, N. Y., at $105 per year, is due to the use of water-power.

THE CINCINNATI WATER-WORKS REPORT FOR 1889.

THE Board of Public Improvements of Cincinnati is taken to task by the local papers for the non-publication of the Cincinnati Water-Works report for 1889, which is said to have passed into its hands formally and regularly. The interesting question is now asked: "What did the Board do with the report? The burning of the court house is said to have covered a multitude of sins. What did Moore's unfinished report contain that it should have been suppressed or spirited away by his successor? It contained, at all events, a correct and reliable record of the pumping capacity and water supply daily for the year up to and including December 31, 1889. The reservoirs were then full of water and the machinery doing satisfactory duty."

THOMAS DOWD, Superintendent of the Orange, N. J., Water-Works, says that the trouble with the city water, which, at present, has a disagreeable smell and is thought unfit for drinking and domestic use, is caused by the presence of vegetable matter in the bed of the reservoir. Every freshet has brought more or less dead leaves, weeds and other debris of a vegetable nature which has settled in the reservoir, and the recent hot weather acting on this has caused fermentation enough to result in the present condition of the water.

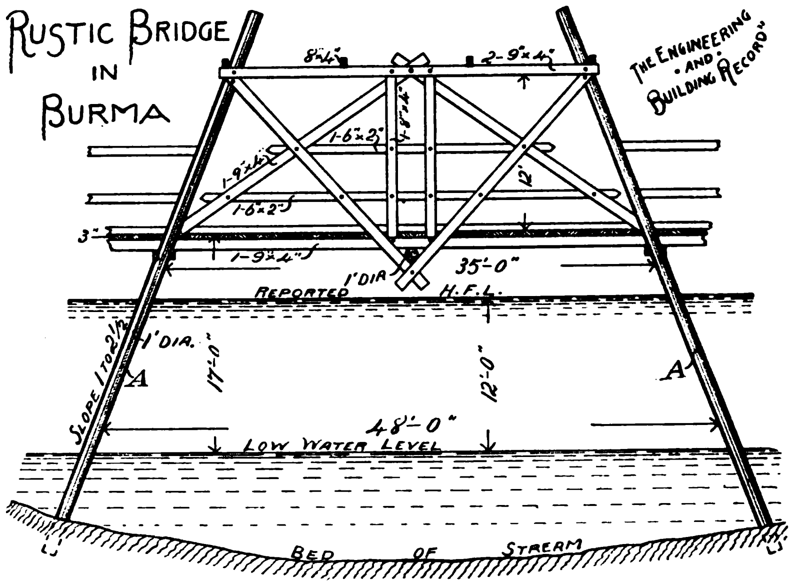
A SCHEME for a grand avenue along the Delaware River front, at Philadelphia, provides for a street 200 feet in width. It is thought that such a street would meet all the requirements of commerce.

THE HATTERAS LIGHTHOUSE.

THE Lighthouse Board has awarded the contract for the construction of the proposed lighthouse* on the Outer Diamond Shoal of Cape Hatteras, North Carolina, to Anderson & Barr, of Jersey City, at their bid of $485,000. The general outlines of the plan for the lighthouse were laid down by the Board, leaving each bidder to furnish his own plans and specifications for doing the work. Anderson and Barr built the lighthouse on the Fourteen Foot Bank in Delaware Bay, and they will follow the same method employed there in building the Outer Diamond Shoal light.

This shoal is the most dangerous point on the entire Atlantic coast, and the difficulties in the way of erecting a lighthouse there are greater than at any point where a similar structure has ever been placed. The contractors will build an immense iron caisson, surmounted with a hollow iron cylinder, and will tow this structure out to the shoal, either from Norfolk or from Hatteras Inlet. It will be sunk on the shoal, in about 24 feet of water, by weighting it down with blocks of stone. When it rests evenly on the sands, the work of excavating will be begun by a force of men inside the caisson, the excavated material being carried up through the cylinder.

The shoal is composed of shifting sands, and it is not known how far down the caisson may have to be sunk. As soon as the base of the caisson rests on a good foundation its interior will be filled up solid with concrete. The cylinder on top will also be filled with concrete to the height of 35 feet above the water level. This base will be surrounded by rip-rap work of stones weighing not less than two tons each, extending to a distance of 400 feet on all sides of the tower.



The lighthouse itself will be nine stories in height, each story containing one room. The first floor is to be a storage room for coal, wood, fresh water, and three lifeboats. On the second floor will be the fog signal apparatus. The third floor will contain the fire-proof vaults for the storage of oil and large tanks for salt water, with storage room for a year's provisions for four men. The next five floors are to be living rooms. Above these are to be the watch room and lanterns. The superstructure is to be of iron lined with brick. Work on the lighthouse is to be commenced within a month, and it is to be completed within two years. The contractors are to maintain the light for one year before its acceptance by the Government.

A RUSTIC BRIDGE IN BURMAH.

AS AN example of native construction without any engineering aid, the accompanying illustration of a bridge in Burmah is prepared from a recent issue of *Indian Engineering*. The bridge consists of 18 spans, the details of one of which are clearly enough shown in the longitudinal section given. In some of the spans the posts A A are vertical. Lateral stiffness is said to be sought, but ineffectually, by bracing the bridge to a couple of side piers.

The bridge was erected by local subscription, and cost about Rs. 6,000.

NEWARK'S WATER WORKS *VERSUS* PASSAIC'S SEWERS.

THE Newark Water Works supply a population of about 200,000 persons with water taken from the tidal portion of the Passaic River, and the City of Passaic, with a population of about 12,000, situated 4 or 5 miles above the water works intake, is constructing a system of sewers to empty into the same stream.

The Newark Aqueduct Board having in vain protested against the undertaking of this work, applied to the Chancellor for an injunction to restrain the City of Passaic from discharging its sewage into the river, alleging that such discharge would materially pollute the water to the injury of its business and the health of those whom it supplied. This application was denied, and an appeal was taken by the Aqueduct board to the New Jersey Court of Errors and Appeals, where the decision of the lower tribunal was affirmed.

This case, involving as it does, the right of municipalities to use navigable streams for sewage disposal and water supply, is of great interest to all who are either officially or professionally concerned in such matters, and the following extracts from the decision of the Chancellor, and the argument of the counsel of the Board on the appeal, will enable them to form a clear idea of the points in dispute.

In denying the application for an injunction the Chancellor held:

1. That the water of the Passaic River, where the tide ebbs and flows, belongs to the State, for uses common to all its citizens.

2. That the city of Newark has no special rights in that water, either by reason of its riparian ownership on the river, or by grant from the State, which may be injured by the apprehended nuisance, and enable the complainant, by showing an apprehended injury, distinct from that which will be suffered by the other inhabitants of this State, to maintain its individual suit to restrain the nuisance.

3. That, at best, such special rights have not been established by adjudication in this State.

4. That the complainant is not in position to ask for a preliminary injunction when the right on which it founds its claim is, as a matter of law, unsettled.

5. That the proceeding in equity to restrain a public nuisance is by information by the Attorney-General.

6. That the statutory authority to the complainant to maintain a suit in equity for nuisance to water courses connected with its works, did not constitute it a public agent to sue to restrain a public nuisance, but merely clothed it with power to sue, as an individual might, for the protection of private property.

7. That an injunction to restrain a nuisance will issue only in cases where the fact of nuisance is made out upon determinate and satisfactory evidence, and that, if the evidence be conflicting, and the injury be doubtful, that will constitute a ground for withholding the injunction. And if the nuisance be merely apprehended, it must appear that apprehension of material and irreparable injury is well grounded upon a state of facts which show the danger to be real and immediate.

8. That such conditions of fact do not appear in this case.

In giving his reasons for this decision, the Chancellor notes that the sewers at present contemplated aggregate 3,650 feet in length, and will receive the sewage of 1,639 people, amounting, with factory waste, to 60,000 gallons a day, rain water being excluded. It is also noted that last year 20 per cent. of the deaths in Passaic were from typhoid and scarlet fevers, diphtheria, cholera infantum and dysentery, as it is from the excreta of persons suffering from such diseases that dangerous pollution of the water is principally feared.

The contentions of the respective parties are thus set forth:

"The complainant takes the position in the first place, that the proposed sewage will pollute the waters that it supplies to Newark and other municipalities, and will thereby create a nuisance especially injurious to the complainant; and, in the second place, if it should be determined that the complainant will not sustain a special and distinct injury, it is, nevertheless, empowered by special statutory authority, to maintain this suit if injury will result to it at all, though it be merely in common with the remainder of the public. To this the defendants reply: First, that the complainant has no right in the waters of the Passaic River which is not common to all citizens of this State, and that an injury to such a right cannot result in such a special and peculiar injury that will enable the complainant to maintain this suit in its own name; second, that in absence of such special injury it has no authority to maintain this suit; third, that if, under the legislation from which it derives its powers, the complainant has obtained a distinct right to the water of the Passaic, such right does not clearly appear, and should be established at law before the issuance of the injunction sought; and, fourth, that, in point of fact, the proposed discharge of the sewage will not pollute or otherwise injuriously affect the waters of the Passaic at the Newark intake."

In commenting on this the Chancellor says that riparian owners on navigable tidal streams have no special rights therein, except the contingent one of accretion, and merely gain by their position a greater convenience in the use of rights common to all. In a navigable but non-tidal stream, however, the title of the riparian owner extends to the land under water to the middle of the stream and to such use of the water as will not interfere with navigation or the rights of others. He, therefore, concludes that as the Newark intake is on tidal water, that city has no special right in the water by virtue of its riparian ownership, and, further, that no such right has been given by any special legislation. It follows from this that if Newark has no special right in the water she can suffer no special wrong by its pollution, and is, therefore, not in a position to complain of such pollution as a private injury, the difference in her case being one of degree merely and not of kind.

In regard to the claim that the consequences of the proposed sewerage will be so disastrous and irreparable that the application should not be dismissed without consideration of its merits, he states it to be a well settled rule of equity procedure that an injunction to restrain a nuisance will issue only on determinate and satisfactory evidence, and that if the evidence be conflicting and the injury doubtful that will constitute a ground for withholding the injunction.

He then proceeds to consider the evidence, adduced by the complainant, of Prof. P. T. Austin, of Rutgers College, who, as chemist for the Aqueduct Board for three years past, has made many analyses of the Passaic water. This gentleman, according to the Chancellor, assumes that the sewage of Passaic will reach the Newark intake in a few hours, and proceeds to show the danger to the health of the inhabitants of Newark that will result from the disease germs thus transported. The fact is also mentioned that Charles Jacobson, the civil engineer of the Board, placed four floats in the Passaic River at or near the mouth of the proposed sewer, one of which reached the Newark intake in four hours.

As opposed to this, the evidence of Henry Wurtz, formerly State Chemist of New Jersey, is adduced by the defendant, which goes to show that, according to analyses made by him in 1881–2, almost the whole effect of the sewage of Paterson (then having at least 50,000 inhabitants) had disappeared in a flow of 4½ miles. Mr. Wurtz gives it as his opinion that the nitrogenous and putrescible constituents of the sewage of the City of Passaic will substantially vanish during the downflow of 4½ miles from the sewer outlet to the Newark intake, and states that $\frac{17}{18}$ of the present pollution of the water at the Newark intake is due to the Newark sewage, which is carried up by the tide. He also says that the alternation of the tidal currents will cause the greater part of the Passaic sewage to travel a much greater distance than 4½ miles before reaching the Newark intake, for which reason it must more certainly vanish.

In considering this evidence two circumstances appear to the Chancellor's mind to be important; first, that practically all traces of Paterson's sewage had disappeared in flowing 4½ miles with no tidal currents, and second, that the Newark sewage, though carried by the tide to the Newark intake, had not produced the injury apprehended from the much smaller quantity of Passaic sewage to be emptied into the river much further away.

---

*See Vol. XXI., page 166.

"This experience," he says, "seems to be a complete negation of the danger theory advanced in support of this application, or is sufficient, at least, to render it doubtful whether the danger apprehended is more than chimerical I deem it of sufficient weight to justify me in withholding a preliminary injunction."

He concludes, however, by the admission that it is not a sufficient ground for the refusal of the injunction asked to say that the Newark sewage is a greater and more dangerous nuisance than the sewage of the city of Passaic will be, and that the defendant would have no right to add to existing pollution even in a small proportion.

Incidentally a curious contribution is made to etymological science by either the Chancellor or Professor Austin, it is not clear which, in the statement that "microbes derive their name from the powerful glass by the aid of which it is claimed they may be detected." The word does not yet seem to have found its way into the dictionaries, but is undoubtedly derived from the Greek words *mikros* and *bios*, and means "a little life"

In making his appeal from the decision of the Chancellor, Thomas N. McCarter, counsel for the Aqueduct Board used, among others, the following arguments:

After quoting the substance of the Chancellor's decision he claims first, that "the complainant has such a right in the waters of the Passaic River which flow into its works as will enable it to maintain an action to restrain the nuisance complained of, even if the nuisance be a public nuisance of which the Attorney-General might also complain."

Second, that "assuming the injury apprehended by the complainant and sought to be enjoined to be a public nuisance, complainant had ample legal authority to bring suit to restrain it."

The third claim could not be found in Mr. McCarter's argument as printed, but his fourth claim is that "In the nature of things such use of the water of the Passaic River as complainant or any other riparian owner enjoys is incapable of public or common enjoyment. Every citizen of the State or of the United States may navigate the public waters of the State no matter where he resides, but how can a citizen of Cape May exercise the right of drawing water from the Passaic River? Even an express grant from the State of the right to draw such water would not avail, because the banks of the river are private property on which the grantee would acquire no right but by the consent of the riparian proprietor."

Under the fifth head it is said, "The Chancellor's opinion shows, not that there is any doubt as to the fact that the sewerage of Passaic is about to be emptied into the river in such quantities and of such character as is alleged in the bill, and as near to the complainant's intake (four miles) as is alleged, but the Chancellor is not convinced that, admitting all this, any harm will be done to the water furnished by complainant to its customers."

In considering this point as well as the other claims, Mr. McCarter quotes extensively from various legal authorities and decisions, and goes over many of the admitted facts already discussed by the Chancellor. He also quotes at some length the expert evidence already referred to, and reviews that of Mr. Wurtz, who, according to Mr. McCarter, has arrived "at the conclusion that the impurities now communicated to the Passaic River by the present drainage of that city [presumably Passaic—Ed.] are only about one thirty-fourth part of the pollution which the sewage of Newark inflicts on the river, and that as the soil of the Passaic Valley is light and porous, the objectionable constituents of the drainage now so easily and speedily percolate the soil that the installation of a sewer system could make no important difference in the drainage percolation of this drainage into the river." Referring to Mr. Wurtz's statement that the Paterson sewage had all disappeared from the river in a flow of 4½ miles, Mr. McCarter intimates that there is no evidence that any of it ever got into the river by percolation, sewer or otherwise, and that even if Mr. Wurtz's theory of "the rapid depositing action of aerial oxidation" were correct for the summer time, it would be entirely inapplicable for that large portion of the year when the river is covered with ice.

In answer to the Chancellor's inquiry as to "why, if imperceptible germs of disease, fraught with danger to health and life, continue in water after all traces of the sewage in water from which they come, so far as they can be detected by a chemist, are lost, have not these dangerous qualities become manifested in Newark long before this?" Mr. McCarter quotes from the answer of the defendant and the affidavit of Mr. Wurtz to show that the river water at the Newark intake "is very materially injured and polluted," so "that it was useless and dangerous to attempt to supply the inhabitants of Newark with pure and wholesome water from this source," and that in fact "very recently the authorities of the city of Newark, moved and influenced by the bad quality of the present water supply, entered into a contract for a new and adequate supply from an entirely different source." He alludes to the proposed addition of the Passaic sewage as "the last straw that will break the camel's back," and asks, "if the water is now so bad that complainant was obliged to abandon it for a new supply, must we submit to this additional contamination while such new supply is being acquired?" and then quotes the Chancellor's concluding remark that existing pollution gives the defendant no right to add to it even in a small degree.

Under his sixth head Mr. McCarter calls attention to the fact that it "nowhere appears that the city of Passaic has any authority from the State to use the waters of the river as an outlet for its sewage," and seventh, that even if it shall ultimately prove that all danger from Passaic sewage has disappeared before it reaches the Newark intake, nevertheless the contrary view is so generally entertained that if the proposed plan is allowed to be carried out such a panic will ensue among the citizens of Newark as will cause them to discontinue the use of the water for all culinary, drinking and domestic purposes, causing great public and private inconvenience and great loss of revenue to the complainant, adding, "Language can hardly describe the consternation experienced by the people of Newark when the Chancellor's decision in this case was made public."

The argument concludes with an appendix "containing extracts from encyclopedias, published reports of official boards of health, medical journals and other sources of general information and common knowledge, as to the consequences of water pollution."

ICE FACTORIES AT NEW YORK.

Before the end of August the New York Steam Company expects to be actively engaged in manufacturing ice. Three buildings are now being put into readiness for the purpose.

Factory No. 1 is being erected in the rear of No. 177 Washington Street, near the steam station B. It is a five-story brick and iron building, 25 by 100 feet. This is the smallest of the three, but the daily capacity will be 60 tons. It will have three elevators, and on the first floor will be the storage room, with a capacity of 120 tons. Upon the two top floors there will be cold storage rooms for meats and poultry, Factory No. 2 is being built at No. 525 East Eighteenth Street, in the large yards of the company's machine shops. It will have a frontage of 100 feet and a depth of 100 feet. The producing capacity of this factory will be 120 tons per day, with a daily storage capacity of 240 tons. The plant for Factory No. 3 is being put in on One Hundred and Sixteenth Street, near the East River, among the gas houses. It will be 100 by 100 feet The capacity will be 120 tons daily, with a storage capacity of 240 tons. The builders are at work night and day and the machinery is being put down as rapidly as possible.

The machinery for the Washington Street plant, which will have a daily capacity of 60 tons, will cost $60,000, while the machinery of the other two will cost each $120,000. The ammonia compression system will be used.

Referring to the description of the cast-iron fresh-air inlet described in our issue of August 2, 1890, the Durham House Drainage Company, 158–160 West Twenty-seventh Street, New York, writes that it has manufactured and sold to plumbers such a box since 1884.

The employees at the pumping station of the Troy, N. Y., water-works, sent in a communication to the Board, asking that their salaries be paid weekly instead of monthly, as is now the case. There seemed to be no objection to granting the petition, and the men employed will hereafter be the recipients of weekly payments.

STREET CLEANING PARTICULARS.

In accordance with the suggestion offered in our last issue by Mr. Sylvester H. Martin, Chief of the Philadelphia Street Cleaning Bureau, we have collected data on street cleaning in a number of different cities, retaining, in a measure, the tabulated form of statement used by Mr. Martin.

The following particulars were furnished by Mr. H. S. Beattie, Commissioner of the Department of Street Cleaning and Stevenson Towle, C. E., Eng. of Paving of

NEW YORK

1. What is the population? A. 1,632,798. (Estimate of Health Department.)

2. How often are ashes removed? A. Daily, Sundays excepted.

3. How often is garbage removed? A. Daily, Sundays excepted.

4. How many miles of paved streets? A. 355.83 miles.

Asphalt........	25,585	"	"

Amount appropriated for maintenance of boulevards, roads and avenues, 1889, $100,000.

5. How many miles of unpaved streets? A. 41; 2½ miles country roads.

6. How often are the streets cleaned? A. About one-third of the streets daily; another third tri-weekly, and the remaining third bi-weekly.

7. What is the average width of main streets? A. 60 feet; avenues 100 feet.

8. Are your streets underdrained? A. Yes.

9. How many sewer catch basins? A. 5,209.

10. How often are they cleaned? A. A force of 17 foremen and timekeepers, 5 mechanics, 55 laborers, and 23 horses and carts have been employed to clean pipe sewers and receiving basins, and to do all small repairs. Total length of sewerage, 433.73 miles.

11. Is the above work done by contract or by day's work? A. In so far as it refers to the Department of Street Cleaning, the work is done by day's work.

12 What is the annual cost of cleaning the streets? A. The appropriation for the work of the Department for the present year is $1,255,835.

13. What is the annual cost of removing ashes and garbage? A. $880,000 of the foregoing amount was appropriated for sweeping, and for the collection of ashes and garbage.

14. What is the annual cost of cleaning catch basins? A. $175,000.

15. What is the annual cost of removal of dead animals, night soil and offal? A. $36,000.

16. For the supervision of all above work? A. So far as it refers to the Department of Street Cleaning, $180,000 of the appropriation was set aside for the purposes of Administration.

17. What is the final disposition of the street dirt, ashes and garbage? A. Principally dumped at sea, to which it is taken in scows. During certain seasons of the year a portion of the collections is disposed of for "filling in" along the water front of, or near to, the city, but at an expense, so far, to the Department which varies very little from the cost of "final disposition" at sea. Ashes, garbage and sweepings are collected by carts, from which they are dumped on scows, located at convenient points, for accessibility, along the water front. The cost of this service has averaged 35 cents per load of 40 cubic feet. The cost of towing these scows to sea, or of final disposition, has, until within the past five weeks, averaged 16 cents per load. It is now at least one-fourth less.

18. What is the final disposition of dead animals? A. Taken to Barren Island.

19 Does the city own the plant for street cleaning? A. The Department owns about one-fourth and hires about three-fourths of the plant now used in the performance of its work.

20. Are streets swept by machinery or hand labor? A. Partly by machine and partly by hand labor.

21. What kind of hand-brooms are used? A. Bass and rattan.

Several of the large breweries at Rochester, N. Y., have equipped themselves with special pumping plant to supply them with water taken from the Genesee River at greatly reduced cost. In consequence of this there has been a daily decrease of 400,000 gallons in the consumption of Hemlock water. The breweries use the Genesee water principally for their ice machines, for which it is of good enough quality.

The new customs administrative law, which recently went into effect, at once raised the prices of imported Portland cements.

EARLY CHURCH STRUCTURES.

There are 15 Congregational churches in Connecticut which were erected prior to the current century. Eight of the number were constructed before the Revolutionary War. The oldest church edifice of the Congregationalists in the State is at Abington. It was built in 1751. Three years afterward the Congregational Church at Hampton was erected. The old brick church at Wethersfield was erected in 1761. There is a legend that its solid walls were paid for from the profits realized in the onion trade a century and a quarter ago. The building is the same outwardly that it was when Washington visited Webb in the historic mansion which is still standing within a stone's throw of the church.

The churches at Farmington and Kensington were constructed in 1771. Legislative interference was required in order to settle the differences that prevailed concerning the location of the Kensington church. The structure is of wood, and the wrought-iron nails used in fastening the clapboards to the framework present a strange appearance to the modern eye.

The oldest soldiers' monument in the State is erected on the grounds adjoining this ancient edifice. The Farmington church has been a prominent factor in the history of the denomination. Among the most noted men who have been connected with it is ex-President Porter of Yale University. The two churches at South Britain and Westminster were built in 1770, and the church at East Haven was erected in 1774.

One of the most notable of the later series of church buildings constructed during the last century is at Windsor. It was the place of worship attended by Chief Justice Oliver Ellsworth of the United States Supreme Court, and the old pew that the distinguished legalist used to occupy is still preserved. The church was constructed in 1794. The old church at Centerbrook, in Essex, was built in 1789, and the church at Newington, near Hartford, was erected in 1795.

THE UTILIZATION OF SEWAGE.

In a paper read by Sir Robert Rawlinson before the London Society of Arts on "London Sewerage and Sewage," it is stated that the entire volume of London sewage is now valued at $8,750,000. According to the same authority land is not corrupted by sewage irrigation, but is improved, as the solids out of 100 tons spread over one acre of land would not give a surface deposit of $\frac{1}{100}$ of an inch in thickness. In the discussion which followed the paper, Dr. Charles Drysdale said that all the European nations were looking to England for a solution of the question and many of them had sent engineers over there to study what has been done. Paris has now a very successful sewage farm of 1,300 acres, which produced most magnificent crops, and the effluent was so pure that any one could drink it, as he had done himself. In Berlin, also, where the authorities had sent engineers to study sewage farming, they had about 1,000 acres on the north and south and not a particle of sewage was sent into the river. So far as the disposal of sewage went every possible plan had been tried, and it was well known now, said Dr. Drysdale, that the only possible way of purifying sewage is by passing it through filtering soils.

The New York elevated roads are at present experimenting with various kinds of brake shoes in the effort to find a shoe that will serve without emitting the disagreeable, grinding noises now produced whenever a train is stopped. Thus far gun metal shoes are said to have given good results, and it is thought likely that they will be finally adopted.

ANNUAL REPORTS.

Annual Report of M. J. McCabe, City Engineer of St. Joseph, Mo., for the fiscal year ending April 15, 1890.

The report opens with a table showing the amount and kind of street paving done, and giving the mileage of improved and unimproved streets. Paragraphs are devoted also to grading and macadamizing, and tables are annexed showing the amount of this work done and the cost. Curbs and sidewalks are similarly treated. Sewers and bridges are next considered, and tabulated statements bearing upon them are given. Short sections are devoted to various other subjects such as public buildings, street repairs and street cleaning and lighting, public parks, etc.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

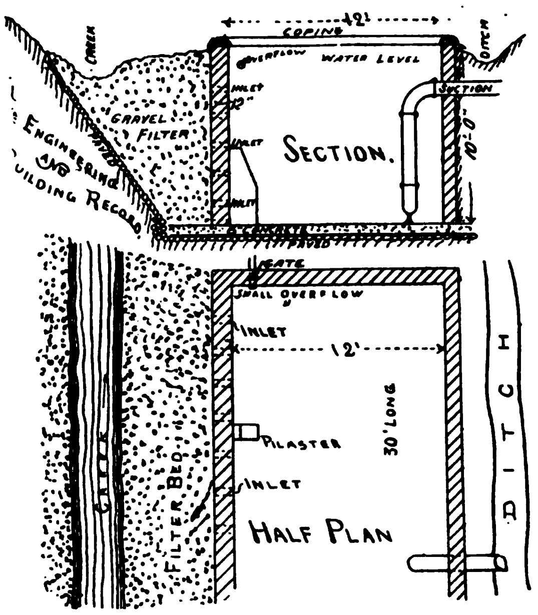
FILTER CHAMBER AT THE GAINESVILLE, GA. WATER-WORKS.

Atlanta, Ga., July 26, 1890.

To the Editor of the Engineering and Building Record:

Sir: I have just finished drawing up plans and specifications for water-works at Gainesville, Ga., and send inclosed a sketch of the filter chamber.

The town will obtain its supply from Castlebury Creek and pump through 8,970 feet of 10-inch main into a standpipe 80 feet high and 16 feet in diameter, and set with its top 162 feet above the central portion of the town.



The flow of the creek is very copious and the supply is greatly in excess of the present demand or need of the town, and the creek is a perfectly clear, pure mountain stream formed by large springs that burst out of the large gravel veins of the mountain, and it becomes a bold branch within a few hundred yards of its source, the entire water-shed is clothed with forest and there is no need for a storage reservoir or settling basin.

I designed a supply well as shown in the cut, 30 feet long, 12 feet wide, and 10 feet deep, lined with a 9-inch wall on the sides where the excavation is made in stiff clay, and a 12-inch perforated wall braced by small pilasters on the side next to the creek. These walls are built of brick laid in hydraulic cement mortar.

The entire area to be occupied by the well and filter is to be excavated beyond the bed of the creek to a depth of 10 feet and the bottom closely paved with the large pebbles and flint rock which are at hand in abundance, and on this paving 6 inches of concrete is to be laid and neatly leveled to form a foundation for the well and filter.

Between the well and creek a filter of clean sand and gravel will be formed leaving a considerable depression along the line of the creek to contract the flow and insure as much as possible the carrying off of leaves, sticks and mud during heavy rains, which, if deposited on the filter would encourage vegetable growth and otherwise impair the efficiency of the filter. The overflow is small and intended only to keep the water fresh, and by constantly skimming off the surface water to prevent the accumulation of animalculæ. It is provided with a gate to be shut during heavy rains to prevent the back water from entering the well except it pass through the filter and the openings prepared for the purpose.

The well is set with its top 18 inches above the highest water mark and so that the creek can be turned through a ditch on the upper side if any repairs are to be made or the filter to be cleaned.

The well is not covered.

The ordinary flow of the stream is in excess of the capacity of the pumps, this fact insures the service of the filter for its entire length. Yours truly,

N. W. Davis, C. E.

DANGEROUS TRUSSES.

To the Editor of The Engineering and Building Record:

Brooklyn, N. Y., August 11, 1890.

Sir: As you are interested in encouraging good building construction, I would like to call your attention to something that seems to me very far from it which I have just observed in Hermann's new theatre building now being erected in Brooklyn. The front, on Fulton Street, is about 35 feet, and the first floor above and next to the street is supported on the side walls and two trusses, if such they can be called, which are shown in the accompanying sketch, and which require no further description, except that the double top chord has two-inch backing pieces between its members, and that the struts are shouldered down to that width and extend up between them. The pieces composing the top chord are not continuous, and are, in one case at least, very roughly butted together at the joints.

The most obvious defect of the whole arrangement is that the two middle struts are absolutely useless, giving no support whatever to the top chord; but in addition to this the end struts have not the proper inclination, which should bisect the angle of the tie rod, and the end plates are so light that they would curl up long before the tie rod had been strained to its full capacity. The top chord also is not properly constructed to resist either transverse or longitudinal stresses.

The floor beams run parallel to the face of the building, and these trusses are at right angles to them and so spaced that one of them supports about 270 and the other about 360 square feet of floor. I believe the New York building law requires an allowance of 100 pounds per square foot for tenement houses and 180 pounds per square foot for public assemblies, for which latter purpose I presume this room is likely to be used. These would give distributed loads of 36,000 or 65,000 pounds on the most heavily loaded truss, which no engineer who will look at it will believe that it could sustain for a moment.

The trusses are weak in so many directions that it is difficult to estimate just what they might carry, but as the central portion of the top chord is practically unsupported for a distance of 18 feet, on which the distributed load might, if figured as above, be 39,000 pounds, it may be worth while to note that yellow pine beams of the same size and span would not be safe for a distributed load of over 11,600 pounds, or less than one-third of that amount.

Even if the full strength of the 1¼-inch tie rod were utilized the whole truss would only be safe for a distributed load of 5 tons instead of the 18 tons that it ought at least be able to carry. For with an area of 1.23 square inches a stress of 12,000 pounds per square inch and an effective depth of 2.6 feet the truss could, as far as the rod is concerned, resist a bending moment of $1.23 \times 2.6 \times 12{,}000 = 38{,}376$ foot pounds, while as the distributed load $= 8 \times$ bending moment $+$ span it is in this case $8 \times 38{,}376 + 30 = 10{,}233$ pounds only.

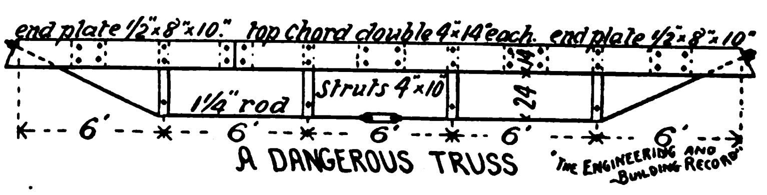
A little further back a pair of heavy iron beams, apparently 20-inch, extend nearly across the building, but for some unaccountable reason stop short of the side walls and rest, one end of them at least, on what seems to be a very inadequate cast-iron column.

All this is difficult to explain on any theory of competent building inspection, and yet the Department of Buildings is not much over a quarter of a mile away, and all I have described is in plain sight from the sidewalk. The construction of a theatre building ought above all things to be most carefully designed and superintended.

Dimensions and distances were carefully estimated, but could not be conveniently measured.

Civil Engineer.

[This communication comes to us from what we have every reason to believe is a perfectly reliable source, and we commend it to the careful attention of those who have charge of such matters in Brooklyn. A theatre building above all others should be above any suspicion of weakness.—Ed. E. & B. Record.]



A DANGEROUS TRUSS

The old Pennsylvania Railroad station at Jersey City was abandoned early this week, and is being demolished to make room for the new structure that is to be erected. The trains are running into a temporary station.

Brooklyn Bridge traffic feels the effect of the outing season and shows it in the returns; but as compared with previous years the traffic for July was larger than in any year, and fully maintains the average annual increase. The total receipts for the month were $85,511.35, an increase of $8,453.81 over July, 1889, and a decrease of $5,924.30 from the June (1890) receipts. The daily average of passengers by promenade and railroad was 99,268 as against 110,701 for June.

LIME INCRUSTATION IN KITCHEN BOILERS.

An article on lime incrustation in kitchen hot-water boilers, published in the London *Builder*, has interest in America, although trouble of the sort is relatively unimportant here. It may appear, however, when water abounds with lime, and account for stoppages or other difficulties. From the article we reproduce the following:

"Our supply of hard water may be considered to be limited to that which proceeds either through or from chalk strata, and as this water is usually of a crystal-like clearness, it naturally becomes difficult for the uninformed to make it accountable for the hard, stony deposit (limestone, in fact) that incrusts the inner surfaces of these and of steam boilers.

"The supply of this hard water is confined to districts where chalk abounds in the soil, and the degree of hardness naturally varies with the nature of the ground. In the south of England, including London and many counties south of London, nearly all the water is more or less hard, but in the north of England the water is of quite a different character, and hard water is, to a great extent, unknown—so much so that vast quantities of boilers (for kitchen ranges) are made without manlids or any means of removing any incrusted deposit.

"When a new boiler is first charged with this hard water and sufficient heat is applied, the result is to drive off the proportion of acid gas, which goes to make the carbonate into bicarbonate of lime, and the latter is transformed into the former again, and, being insoluble, it is precipitated, forming a thin film or coating upon the inner surface of the boiler; this precipitation does not wholly take place immediately heat is applied, but proceeds slowly until boiling takes place and steam is formed, when the chief precipitation is effected. It is almost needless to add that the greatest quantity of deposit is found at that part of the boiler where the greatest heat is felt, but this may be more fully entered into when describing boilers.

"The deposit which is effected when using a boiler but once is a very minute quantity, but when we remember that the same water does not stay in the boiler (when the apparatus is at work) more than a few moments, and fresh water is being continually brought to the heated surface by reason of the circulation, we can then understand why the deposit seems to accumulate so rapidly, especially as the heated and (wholly or partially) softened water is being continually drawn off for domestic uses, and entirely fresh takes its place.

"The average hardness of London water is about 16 per cent., and a range boiler in regular daily use will have a ½-inch deposit of 'fur' within it after six months' use. No rule, however, can be laid down to ascertain at what rate the deposit accumulates, as, although it is easy to find out the degree of hardness of the water, the result is chiefly governed by the efficiency or non-efficiency of the boiler in its heating capabilities, whether the water is nearly always boiling, or whether it seldom reaches this temperature; and again greatly by the quantity of water used, as every drop of fresh water introduced (to replace that drawn from the taps) has its portion of lime to deposit.

"In the counties south of London, particulatly Sussex, the water is very strongly impregnated with lime, so much so that an ordinary-sized boiler will commonly become sufficiently incrusted in from 12 to 18 months to bring about its fracture.

"The deposit partakes of a variable degree of hardness or solidity, that which is the most dense causing the boiler to fail the earliest, and that which is most porous permitting the boiler to render the longest service. With the different London waters the deposit is of a fairly similar character, being very dense, and, in many instances, closely resembling ordinary limestone; and when this has become of about two inches in thickness (about two years' use usually) it is sufficient to prevent the water having any contact with the boiler plate, with the result that the iron is destroyed by the action of the fire, the same as if the boiler were empty. In instances where the deposit is of a more porous or of a scaly character, it naturally requires a thicker deposit to bring about this result.

"The failure of the boiler always shows itself in the form of a small crack or fissure, not a hole in the common sense of the word; and this fissure is rarely larger than one inch in length by one-sixteenth in breadth, for the simple reason that so soon as the fracture takes place water proceeds from it in a greater or less quantity, and this prevents the fire being ignited, and without the fire, of course, no further damage can be done.

"There are two remedies for this trouble, one being to soften the water by removing (*i. e.*, precipitating by chemical action) the lime in solution; or, secondly, by having the 'fur' removed at regular periods.

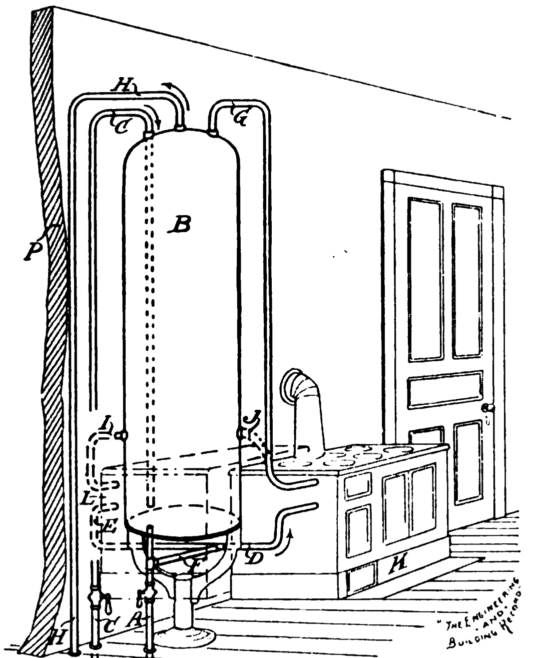
"The first hardly comes within the province of these papers, yet it might be mentioned that whatever process is adopted the softening must be done in a separate cistern, as it would not do to have the precipitated lime carried into the service pipes which run from the house cistern, and each supply of fresh water must be operated upon; and it must be borne in mind that softened water is not agreeable for every purpose, although it may be beneficial to boilers.

"The best remedy and the least expensive is to employ a workman to clean out the incrusted deposit at regular periods. This remedy is, perhaps, sometimes a source of inconvenience, owing to the fact that when this cleaning takes place the kitchen range cannot be used, and, under the most favorable circumstances, this work cannot be done in less than two hours; with some ranges it takes more than a day. The time occupied is to a great extent governed by the amount of trouble experienced in removing the manlid of the boiler. Special means should be provided to make the lid easy of access and removal; but more than three-fourths of the kitchen ranges in the market have no provision of the kind, and the range has to be dismantled and partly unset for the purpose of exposing the boiler manlid.

"In 'cleaning a boiler,' as it is called, the workman has first to get at the lid of the boiler, then to unfasten and remove it; the 'fur' is then loosened with a chisel or other suitable instrument—workmen often have some fancy tool of their own for this work—after which it is removed by the hands and the lid repacked and fastened, and whatever parts of the range have been removed, replaced. Of course, the quantity of 'fur' that has to be removed will govern the time the work occupies to some extent, but the most troublesome cases seldom take more than two hours after the lid of the boiler is removed."

HEATING A BOILER FROM TWO WATER BACKS.*

In a summer cottage at Far Rockaway, L. I., it was desired to have one boiler supply both kitchen and laundry and be heated at will from either range. K is the kitchen and L is the laundry range set back to back against a partition P. B is a 50-gallon boiler receiving cold water through a pipe C and supplying hot water through a pipe H. The sediment pipe A has branches D and E to both water-backs. When the kitchen range is used the circulation is through the pipes F, D and G, but when the laundry range is used it is through the pipes F, E and I. The pipe G was first connected to the boiler at K, as shown by the dotted line, but did not give good circulation. The present arrangement is satisfactory. The diagram is made from data furnished by John Renehan, New York City, who designed and executed the work.



HEATING A KITCHEN BOILER FROM TWO WATER BACKS.

Referring to the article entitled, "How City Water May Be Wasted," published in our issue of August 9th, the National Meter Company, of New York, write that the table giving the discharge of water per minute through various sizes of orifices at different heads, which we credited to the annual report of the Zanesville, Ohio, Water Works, first appeared in their book on "Statistics, Water Rates, &c."

HEATING AND VENTILATING SCHOOL HOUSES.

(Continued from page 155)

In discussing Mr. McClintock's paper the question of how to readily determine the amount of carbonic acid in the air was brought up. Mr. E. P. Adams thought that the ordinary way of discovering the approximate percentage of carbonic acid gas in the air, might be modified so as to make it easy for a teacher to tell when the air has become too impure to be healthful. The proposed method was to have several bottles, one containing, say, 100 cubic centimeters, another 200, and another 300, and a saturated lime-water solution. The bottles being filled with water, commence with the smallest bottle and carefully empty the water, introduce the standard quantity of lime water, say 15 cubic centimeters, and shake the bottle. The purpose of pouring the water out is to bring into the bottle some of the air which is in the room. If the water becomes turbid the quantity of carbonic acid gas is easily determinable from the relative proportion of the lime water and the air in the bottle.* If it is not indicated by the first bottle, the next larger quantity may be used, and so on until you find what quantity of air does render the lime-water turbid. After the standard of the room has been determined a bottle of that size should be kept on hand, filled with water, and if the teacher thought that the air was becoming impure, he could simply pour out the water, introduce the lime-water, and shake it, to test the degree of impurity relative to the standard.

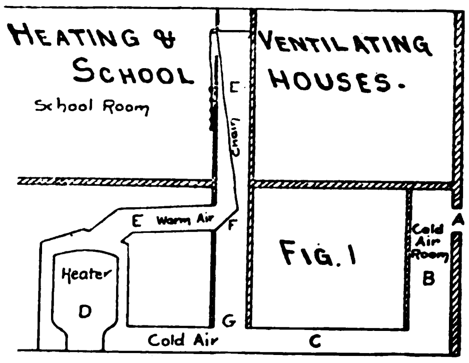


FIG. 1

Prof. S. H. Woodbridge said that there had been an instrument lately devised by Professor Wolpert for the indication of atmospheric vitiation, or rather, for indicating the proportion of carbonic acid in the air, which may take a place, for that purpose, with the thermometer for the indication of temperature, and the barometer for the measurement of atmospheric pressure.

It is essentially this: A shallow glass vessel about 6 inches in diameter and 2 inches deep is partly filled with a standard solution of carbonate of soda, colored a bright carmine by phenol-phalin in solution. On the surface of this liquid floats an air-tight metallic box, which may be contracted or enlarged within narrow limits by a conveniently placed thumb-screw. To the edge of this is attached a glass syphon tube, one leg of which is immersed in the liquid, and the other end drawn down to a much smaller calibre, overhangs the edge of the glass vessel. The rate of flow through this syphon is regulated by the distance by which its outside end is below the level of the liquid in the vessel, and this is in turn regulated by the buoyancy of the float. The liquid drops from the syphon into an angular trough, inclined and open at its lower end, and having suspended from its tip a small sized cotton string of some 15 inches length, in such fashion that the liquid will follow down the cord, coloring the string a bright carmine. The string is weighted at the lower end by a glass ball, and the drip is caught in a small receiving vessel.

If carbonic acid is present in the air, it combines with the carbonate of soda, and forms a bi-carbonate, and in this solution the coloring disappears. The greater the proportion of carbonic acid present in the air, the less the time of the exposure must be to change the carbonate to a bi-carbonate, and the shorter the length of the carmine colored string. Behind the string is a scale showing the points at which the coloring should disappear for certain proportions of carbonic acid in the air. The discoloration is not sharply marked, but sufficiently well for a trained eye to fix the point to within a fraction of one part of carbonic acid in ten thousand of air.

---

*Several different solutions of this problem have been given from time to time in the columns of this journal and are published in "Plumbing and House Draining Problems," pp. 154 to 177, but the example here shown illustrates a different arrangement from any heretofore described.

*With 100 cu. cm., 6 parts in 1,000; 200 cu. cm., 12 parts; 300 cu. cm., 8 parts; 450 cu. cm., 6 parts.—Billings. P. 22.

The carbonate solution must be renewed as often as once a month, and the string renewed or washed frequently enough to keep it clean. The greatest source of error is in judging the point of discoloration by the eye.

Mr. McClintock thought that the amount of air admitted into a room should never be left to the discretion of either the teacher or the janitor; it should be made absolute. The degree of temperature at which it is admitted may, of course, be left to the teacher; but the amount of air never should be, that is, the amount of air coming into the room should be through a certain sized aperture, based on the number of pupils that there are in the room, and the amount required per pupil per minute. The only opportunity of regulating it that should be left to the teacher should be in regard to whether the temperature should be 68 or 70 or 72.

Mr. McClintock illustrated his remarks by the accompanying sketch (Fig. 1), in which A is the opening into the side of the building, where the cold air comes into a chamber B; leading out of the bottom of chamber B is a flue C; D is the heating apparatus, of whatever shape it may be desirable to have it, where the air is heated. The flues for warm air into the different rooms are, say, at E-E, so that the air passes up into different rooms. The air comes in from the outside, envelops the heater, and becomes warm; then it passes up one of these flues E at a temperature sufficient to warm the building. At F is a damper connected with the school-room, so as to be worked by the teacher by means of a chain passing over a pulley. In the first place this flue goes to the bottom, and has an opening G, so that the bottom of this is always full of cold air. When the damper F in the flue back of the heater is raised, the air, unwarmed, passes directly up the flue into the building. If you turn that damper down across the flue, then the air passes over the heater and becomes warm, and passes up at whatever temperature it may be raised to by reason of its coming in contact with the heater. Then if it is desired on the part of the teacher to change the temperature at all by working this damper, one way or the other, the cold and warm air are so mingled as to enter the room at the required temperature.

(To be continued.)

STEAM HEATING IN THE MECHANICS' BANK BUILDING, NEW YORK.

PART III.—ELECTRO PNEUMATIC VALVE ARRANGEMENT, AIR PUMP AND BLAST REGULATORS.*

FIGURE 8 shows the valve case in the engineer's room, A A, etc., are 54 valves (as shown in Figs. 4 and 5, p. 156) that control all the radiator valves and fresh air dampers in the building. Steam is delivered through pipe O to the special air pump P that discharges through pipe G to compressed air tank F, from which the pipe D supplies all the branches C C, etc., to the valves A A. B B, etc., are the pressure pipes to the radiator valves (see Fig. 7 p. 156), some rooms have two or more radiators controlled by one thermostat, in that case each steam valve has a separate pipe branched into pipe B so that all are simultaneously operated by one valve A. H is an ordinary pressure gauge whose needle I is connected to one wire R of a circuit which is completed when the needle indicates 10 pounds on the scale and makes a contact with wire K, or at 15 pounds with wire J.

"THE ENGINEERING AND BUILDING RECORD"

J K and R are connected with one of the valves A that controls the pressure in pipe L and operates valves M and N simultaneously. When the needle is at K, M and N open and admit steam to the pump and air to the tank, when the rising pressure carries the needle to J. M and N close, shutting off the steam and preventing loss of pressure through pipe G.

Q Q, etc., are switches, corresponding to valves A A, etc.; each has three positions in which it will set the valve open, closed, or when in normal position allows the thermostat to control the valve, thus enabling the radiators to be regulated at will from the engine room regardless of the thermostats.

E E, etc., are the sal ammoniac batteries for the thermostat currents, reserve cells are also provided in excess of the number constantly required and are arranged so as to be instantly switched on and off for replacing, repairs, etc., without any trouble of connecting, moving, etc.

Figure 9 shows the apparatus governing the fresh air blast to the first and second floors through conduits M, Fig. 1, page 140. When the damper S is down, in the position shown, all the blast is forced through the radiator box L and delivered hot. When the temperature of the room rises to the point at which the thermostat is set, it operates the regulator J, whose arm K raises to R' and turns the damper, as indicated by dotted lines, stopping the passage of the air through the radiator box, and leaving it to be delivered through M directly from the blast main and at the temperature of the outdoor atmosphere. Since this blast may be too cool to deliver from the registers, its temperature is governed by the regulator *j*.

A certain temperature is fixed, say 50 degrees, below which the outside air shall not be admitted without warming or "tempering." A thermostat, set at this degree, is placed in the blast main and connected to regulator *j*. When the temperature is low the operation of *j* throws its lever *r* and the link *v* and latch *z* into the position shown, so that *z* engages lever R and prevents its raising damper S beyond a certain point, which is readily adjusted by connecting link Q to any one of the holes in R. This position of damper S admits part of the fresh air direct, and part from the radiator box L, the different proportions being readily determined by experiment. When the outside temperature rises above the fixed point, the thermostat shuts off the pressure in *j*, and *r*, *v* and *z*, moving in the directions indicated by arrows *w w w*, withdraw latch *z*, disengaging lever R, so that it may rise to its full stroke and close damper S so as to entirely shut off the heated blast.

C and *c* are compressed air pipes, and T is a stop to prevent lever R from being drawn backwards by the latch *z* on its back stroke.

z is pivoted at *x*, and is drawn towards R by the spiral spring *t*.

Regulators J and *j* are alike, and are constructed as shown in Fig. 10; their operation is similar to that of valve A, shown in Figs. 6 and 7, p. 156.

Compressed air from tube C enters the chamber M between shell J and rubber diaphragm I (which has an initial maximum curvature from a spring or imposed weight), and raising the diaphragm carries lever R to R'. When the air pressure is withdrawn the moving parts return to their original positions, as shown.

The reference letters have the same significance as in Fig. 6, p. 156.

The steam-heating in this building was done by Baker, Smith & Co., of N. Y., and the regulating apparatus is of the Johnson heat regulating system, and was furnished by the Metropolitan Electric Service Co. of N. Y., whose manager, S. J. Bailey, and superintendent, T. L. Bealle, explained its operation to a member of our staff, who prepared the sketches and description from the finished plant.

SIZES OF SEWERS.

IN his report on the Victoria, B. C., sewerage system, Mr. Rudolph Hering says that the least size of the public sewers should be eight inches, and that abundant experience has proven that a smaller size is objectionable. In Memphis, Tenn., where six-inch pipes are extensively used, from 100 to 200 stoppages occur per annum, which, in many cases, mainly from the absence of manholes, require a digging up of the street to remove them. Eight-inch pipe has been found quite suitable in many cities of the United States.

With regard to the size of the main pipe leading from the house to the sewer, the custom in most cities is to make this pipe six inches in diameter if made of earthenware. Mr. Hering fully indorses this custom. It is true that in a number of cities smaller pipes, even to four inches in diameter, have been used. If well laid, a four-inch pipe may give no trouble, and there are many instances of this kind. But there are also instances of considerable trouble due to this small diameter. In Memphis, again, the last biennial report states that there were as many as 2,000 stoppages per annum in the four-inch house pipes, requiring a plumber's services in each case to remove the same. In large cities, or in one where a strict control cannot be kept of the laying of house pipes, Mr. Hering thinks it is false economy to make them less than six inches in diameter, unless they are of cast iron from the house up to the sewer junction.

A TWO HUNDRED foot length of the new Lick Run sewer, at Cincinnati, O., has caved in, and about 1,000 feet more are expected to fall, owing, it is said, to faulty engineering.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department*. Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

HOW MANY LEAKS ARE ALLOWED IN AMERICAN WATER MAINS?

David Franklin, of Saratoga Springs, N. Y., writes: "With regard to question raised by William Perry, Jr., in your issue of August 9, as to number of leaks allowed by American engineers in water mains per mile laid, I would say that in 1884 about four miles additional mains were laid in this place. The contractor, Adam Miller, guaranteed the work for six months; I was employed by him to do any repairs that might be needed. During the past six years I have only had to recalk six joints. Our system is the Holly. The ordinary pressure at works is 90 pounds and at the highest parts of the town, 45 pounds. I never heard of making allowance for leaks in mains."

PRACTICAL CIVIL ENGINEERING AND SURVEYING SCHOOLS.

S. P. Stabler, of Lower Peach Tree, Ala., writes: "Will you kindly furnish me the names of several good institutions where practical civil engineering and surveying is taught?"

[We are a little in doubt as to the exact meaning of our correspondent when he writes of practical civil engineering and surveying schools. For obvious reasons civil engineering practice cannot well be obtained in an engineering school, though practical surveying is embraced in the courses to a greater or less extent. On the whole it is little more than the theory of the science that the student can hope to obtain at the school. The practical training must be obtained by contact with actual engineering work. Courses of civil engineering are established at Columbia College, New York; Cornell University, Ithaca, N. Y.; the Rensselaer Polytechnic Institute, Troy, N. Y., and at several other colleges and universities. The schools will send catalogues, giving further information, on application.]

DEEP BOREHOLES.

In connection with the reference which we made some time ago to the bore hole at Schladebach, Germany—now the deepest in the world—it is interesting to note that the greatest depth reached until 1883 was 1070.2m. (3,478 feet) in the shaft at Pribram, Bohemia. This has since been exceeded in the following seven cases: Friedrichsane, at Aschersleben, 1080.22m.; Inowrazlaw, 1104.65m; Sennewitz, at Halle, 1111.45m.; Lübtheen, in Mecklenburg, 1203.70m.; Sperenberg, near Berlin, 1273.01m., Lieth, near Altoona, 1338.00m; and Schladebach, 1748.40m. The increase in temperature, which according to previous observations was about 1° Cent. per 39¼m, (1° Fahr. per 71 feet), averaged for an increase of 1° Cent., at Sperenberg, 32m.; at Sudenburg, 32.36m.; at Leith, 35.07m.; at Sennewitz, 36.66m.; and at Schladebach, 36.87m. In the last borehole, at a depth of 1716m., almost the highest temperature observed in the interior of the earth was recorded, namely, 45.3 deg. R. (135° Fahr.); but the increase was uneven in consequence of the different heat-conducting qualities of clay, limestone, sandstone, rock salt, &c., and also because of the influence of water from springs of various temperatures encountered during the boring, besides the artificial effects of the drilling work. The observations at Schladebach are the most reliable, particularly those bearing on the deepest points, because they followed the work in its progress, and were made in a borehole with no tubing. At a depth of from 1266m. to 1716m. the temperature rose 1° Cent. for 39.55m.

RULES FOR THE INSTALLATION OF ELECTRIC LIGHTING AND MOTIVE APPARATUS.

The following rules and regulations for the safe installation of electric plants are submitted by the Boston Manufacturers Mutual Fire Insurance Co., after a thorough and exhaustive revision and long consideration by competent experts. They are believed to be consistent with all that is yet known upon the subject of possible fire hazards from such apparatus. It may be stated that when electric lighting was first introduced, many years since, in mills or works insured by the above Company, mainly on the arc system, they had twenty-three cases of fire in sixty-one installations, but without any loss, within six months from the beginning. During that period the subject was thoroughly investigated and rules were prepared, by which they have been governed since that time. The rules now presented are a development rendered necessary by numerous inventions and improvements in the applications of electricity to illumination and to the transmission of power. It is claimed that there has not yet been a loss from any fire which could be attributed to electricity, generated for purposes of lighting, or for motive power, in any mill or works insured by the Company; and they hold that a well installed electric lighting system is the safest method of illumination.

The rules were prepared by C. J. H. Woodbury, F. E. Cabot, C. M. Goddard, and S. E. Barton, and are subject to change or amendment, consistently with the future progress of science in the development of electricity.

Dynamos and Switchboards.—1. Dynamos must be located in dry places, not exposed to flyings or combustible material, and must be insulated upon dry wood, filled to prevent absorption of moisture. They must be kept thoroughly clean and dry. They must be provided with a reliable, automatic regulating device, or a competent person must be in attendance near the machine whenever it is in operation. In wiring for motive power, the same precautions should be taken as with a current of the same volume and potential for lighting.

Each machine should be provided with a water-proof cover, which should be used whenever the machine is not in operation.

2. Switchboards, or other apparatus near the dynamos for controlling circuits and currents, should be so located that they will be accessible, and open on all sides, and entirely disconnected from all wood-work or combustible material; also kept free from moisture. They should be incombustible, and rendered non-absorbent of water.

Motors.—3. They must be located in dry places, not exposed to flyings or combustible material, and must be insulated upon dry wood, filled to prevent absorption of moisture. They must be kept thoroughly clean and dry. They must be self-regulating, or a competent person must be in attendance near the machine whenever it is in operation. All resistance boxes or devices should be made of non-combustible material, or so located that they cannot communicate fire to any surrounding combustible material. In wiring for motive power, the same precautions should be taken as with a current of the same volume and potential for lighting. The motor (and resistance box) should be protected by a cut-out, and controlled by a switch.

4. Motor cars driven by electricity from a single wire with earth or floor return circuit will not be approved in any building insured by this Company. The use of such single trolley tracks may be permitted, after special inspection, in mill yards where there is no liability of other conductors coming in contact with the trolley wire, and where the conditions of the position of the generator is such that the ground circuit will not impose any fire hazard on the property.

5. Wires for electric lighting or stationary motors will not be permitted in the same circuit with trolley wires with ground return—the Stock Insurance Companies will permit such installations, subject to special inspection and agreement, on payment of a suitable charge for the permit covering this increased hazard—although the same dynamo can be used, if desired, for both purposes, provided that the connection from the dynamo to each of the two circuits shall be by a double-throw switch, so that only one of the circuits shall be in service at the same time. In such case the wires for lighting or stationary motors shall be in the usual manner, entirely on a metallic circuit without ground.

Testing.—6. All circuits should be tested at least twice a day with a suitable magneto, or other approved device, in order to discover any escapes to ground that may exist. One test should be made in the morning, and another in ample time before starting, to remove any defect, should it be found to exist. The rules for testing should be observed in any separate or isolated plant the same as in central stations.

ARC SYSTEM.

Outside Wires.—7. All outside overhead wires must be covered with some material of high insulating power, not easily abraded; they must be firmly secured to properly insulated and substantially built supports. All tie wires must have an insulation equal to that of the conducting wires.

8. All joints must be so made that a perfectly secure and unvarying connection, fully equal to the cross-section of the conducting wire, will be secured—and they should be soldered. All joints must be securely wrapped with an approved tape.

The following formula for soldering fluid is recommended: Saturated solution of zinc, 5 parts; alcohol, 4 parts; glycerine, 1 part.

9. Care must be taken that conducting wires are not placed in such position that it would be easy for water or any liquid to form cross-connection between them, and they should not approach each other nearer than one foot. The wires must never be allowed in contact with any substance other than air, and their proper insulating supports; except that service wires with special insulation may be permitted to touch foreign substances.

10. Conducting wires carried over or attached to buildings, *must* be at least seven feet above the highest point of flat roofs, and one foot above the ridge of pitched roofs. Lines constructed subsequent to the adoption of these regulations should not be run over and attached to buildings other than those in which the light or power is being, or is to be used, but should be on separate poles, or structures, where they can be easily reached for inspection.

11. When they are in proximity to other conducting wires, or any substance likely to divert any portion of the current, *dead, insulated* guard-irons must be placed so as to prevent any possibility of contact in case of accident to the wires or their supports. The same precautions must be taken where sharp angles occur in the line wires, and also where any wires (telegraph, telephone, or others) could possibly, owing to their position, come in contact with the electric light wires.

12. Overhead wires from the main circuit or pole in the street to the terminal insulators attached to buildings, and at a point where they enter a building, must not be less than twelve inches apart They must be rigidly and neatly run and supported by glass or porcelain insulators or rubber hooks.

13. Service blocks must be protected by at least two coats of water-proof paint over their entire surface; and, when used to support rubber hooks, must have at least one inch of wood between the inner end of the hook and the back of the block.

14. For entering buildings, wires with an extra heavy water-proof insulation must be used from the terminal insulators through the walls from the outside to the inside of the building. They must loop down, so that water may drip off, without entering the building, and the holes through which they enter should, where possible, slant upward.

15. Wires must enter and leave the building through an approved cut-out switch, which must be "double contact," and should effectually close the main circuit, and cut off the interior, when turned "off." It must be so constructed that there shall be no arc between the points when thrown "on" or "off." It should be automatic in its action in either direction, not stopping between points when once started. It should indicate upon inspection whether current be "on" or "off." It must be mounted on a non-conducting base, kept free from moisture, and easy of access to firemen and police.

Inside Wires.—16. Wires must not be concealed, and they must be rigidly kept apart at least 1 foot, unless an *approved, moisture-proof, non-conducting, non-inflammable tubing* is used. This tubing must be sufficiently strong to protect the wires from mechanical injury. It may be fastened to the wall by staples, provided the tubing is not broken or injured thereby. Wires in this class of tubing may be run as near as 3 inches to each other.

17. Conductors in buildings must be thoroughly well insulated with non-absorbent water-proof material, as incombustible as possible, which will adhere to the wire and not fray by friction, and will stand a temperature of 150 degrees without softening.

In places liable to dampness, wires must be thoroughly and carefully run on glass insulators, rubber hooks, or porcelain knobs of suitable size and shape, and the wires must be separated at least 18 inches. They must also be provided with an approved water-proof insulation, or encased in an approved tubing.

When wires pass through walls, floors, partitions, timbers, etc., indoors, glass tubing or so-called "floor insulators," or other moisture-proof, non-inflammable, insulating tubing must be used.

18. All lightning arresters must be grounded outside of building, and preferably connected to a water pipe.

Arc Lamps.—19. The frames and other exposed parts of arc lamps must be carefully insulated from the circuit.

Each lamp must be provided with a proper hand switch, and also with an automatic switch that will shunt the current around the carbons should they fail to feed properly.

Stops of some kind must be provided to prevent the carbons from falling out in case their clamps fail to hold them; and these stops must always be in place.

20. For inside use, the light must be surrounded by a globe resting in a tight stand, so that no particles of melted copper or heated carbon can escape. When any inflammable material is near or under the lamp, the globe must be protected by a wire netting. Unless a very high globe, which closes in, as far as possible, at the top, is used, it must be provided with some protector or spark arrester, reaching to a safe distance above the light. Broken or cracked globes must be replaced by perfect ones immediately. (By inflammable material is meant dry goods, clothing, millinery, and the like in stores; flyings or goods in fabric factories; shavings and sawdust in wood-working shops, or any other substance that can

be readily ignited by droppings or flyings from the lamp.)

INCANDESCENT SYSTEM.

Incandescent Lamps on High-Tension Circuits.—21. The rules for running wires for arc lamps apply also to incandescent lamps on circuits having a potential of over 350 volts. Incandescent lamps in single series on high-tension circuits must be provided with a suitable hand-switch, and also with an automatic device capable of shunting the circuit across the terminals of the lamp, should the carbon filament break. When incandescent lamps are in multiple series, the hand switches must not control less than a single group of lamps, each of which may be provided with an automatic shunt, as above. Electro-magnetic devices will not be accepted as suitable for this purpose. Any method of distributing current to incandescent lamps on high-tension circuits, other than as above provided for, must receive approval before being put to use.

Outside Wires.—22. The rules 7 to 15 for outside arc wires also apply to outside incandescent wires, except that a cut-out switch in the circuit entering the building will not be required, but the wires from main circuit to main cut-out, inside of building, must be separated by a distance of not less than 6 inches, for currents having an electro-motive force of 350 volts or less, and this distance must be increased for currents of higher potential. They must also be rigidly and neatly run, and must be supported by glass or porcelain insulators, or by rubber hooks.

Underground Services.—23. Where underground service conductors enter a building, special care is necessary that they shall not come in contact with each other, or be placed where there is any risk of disturbance by moisture or mechanical injury.

There shall not be any free opening from underground wire conduits to buildings.

The service must not end in any place where it would be unsafe or undesirable to place a cut out, but should be continued by means of specially insulated conductors (and a space of 10 inches should be maintained between them) to a suitable location.

Inside Wiring.—24. For inside work, no wire smaller than No. 16 " B. & S.," or No. 18 " B. W. G.," will be approved. Before using any new form of insulation, the approval for its use under the proposed circumstances must be secured. The use of lead-covered wire, or wire the covering of which contains paraffine, is prohibited.

25. Moldings with open grooves laid against the walls or ceilings will not be approved. A wood molding with dividing strips between the grooves, at least half an inch in thickness, and having a backing of at least ¼-inch thickness to intervene between the wire and the wall or ceiling of the building, the backing to be protected by at least two coats of water-proof paint, and the molding of such shape as to protect the wire from moisture, will be approved. Moldings must not be used in wet places.

26. Wires laid in plaster, cement, or other similar finish, or run over surfaces furred off for plastering, will not be approved, no matter what insulating covering is used. An approved moisture-proof, non-inflammable, insulating tubing or conduit may be used in such places. This tubing must be of sufficient size and so placed that the wires may be withdrawn and replaced at will. All joints and bends in this tubing must be made with suitable devices adapted especially for the purpose. Where this is done in such a way that the joints are moisture-proof, a double-braided cotton insulation, rendered non-inflammable, may be used.

A separate tube must be laid for each wire, except in the case of "taps" for not more than fifteen amperes, in which case conductors having insulation of cotton or other material which will readily carbonize, will be required. If a moisture-proof covering is desired, it must be placed outside the two conductors, and not between them. In other concealed places, such as unfinished lofts, between floor and ceiling, in partitions, etc., all wires must be covered with approved moisture-proof insulation, and fastened at distances not exceeding ten feet so as to preserve at least 2½ inches between the wires or any other electrical conductor. In lieu of such construction an approved moisture proof, non-inflammable, insulating tubing or conduit with approved moisture-proof joints may be used, and the same rule as to insulation will be applied as in the case where the tubing is buried in plaster or similar material. Tubing passing through walls or ceilings must extend at least one inch beyond the finished surface, until the mortar or other similar material is entirely dry, when the projection may be reduced to one-half inch.

Tubes of such approved make may be laid side by side when imbedded in plaster or otherwise. At all outlets to and from cut-outs, switches, fixtures, etc., wires must be separated from gas-pipes or parts of the building by porcelain, glass, or other non-inflammable insulating tubing, and should be left in such a way as not to be disturbed by plasterers Wires of whatever insulation must not in any case be taped or otherwise fastened to gas-piping. If no gas-pipes are installed at the outlets, an approved substantial support must be provided for the fixtures.

Wires of the same polarity, but belonging to the different circuits, or leading to and from a double-pole switch, must not run in one groove, through the same tube, nor in the same slot in a cleat.

27. In dye houses, paper and pulp mills, and other buildings specially liable to moisture, all wires (except those used for pendants) must be separated at least six inches. The wire must be thoroughly and carefully put up, and must be supported by glass or porcelain insulators, or by rubber hooks. An approved, moisture-proof, non-inflammable, insulating tubing will be accepted in lieu of such construction.

28. In crossing any metal pipes, or any other conductor, wires must be separated from the same by a block of wood or other non-conductor of at least one-half inch, and so arranged that they cannot come in contact with each other by accident. Wires should go *over* water-pipes where possible. When wires pass through walls, floors, partitions, timbers, etc., indoors, glass tubing, or so-called "floor insulators," or other moisture-proof, non-inflammable, insulating tubing must be used. Wires must never be left exposed to mechanical injury, or to disturbance of any kind. Wires of the same polarity, but belonging to different circuits, or leading to and from a double-pole switch, must not run in one groove, through the same tube, nor in the same slot in a cleat. Cleats should be made of well-seasoned hard wood (filled to prevent the absorption of moisture), porcelain, or other approved material, and so made as to separate the wire at least one-fourth inch from the building. When secured by cleats not over four feet apart and tightly stretched, wires having a difference of potential of 120 volts or less, and carrying not over ten amperes, should be separated at least 1½ inches; when they are confined in molding, a ½-inch space is sufficient. Mains carrying currents of larger volume should be separated a greater distance.

The use of metal staples for securing wire will not be approved.

29. Where exposed to corrosive fumes, wires should be provided with an insulation that will not be injured thereby; and should be put up in the manner described in Rule 27.

30. All splices in wires must be soldered in accordance with Rule 8. A soldering bolt should be used for this purpose, if possible. Care must be taken not to render the wire brittle by overheating. The insulation of any joint must be equal to that of other parts of the same wire.

Safety Cut-Outs and Switches.—31. Every portion of each installation must be equipped with double-pole, safety cut-outs, that will interrupt the passage of a current in excess of the amount which any portion of the apparatus is adequate to transmit. A cut-out must be placed where the underground or overhead service joins the inside wires, and at every point where a change is made in the size of the wire (unless the cut-out in the larger wire is intended to protect the smaller). The plug or other device for inclosing or supporting the fusible strip or wire should be incombustible and moisture-proof, and so constructed that an arc cannot be maintained across its terminals by the fusing of the metal. No lead or composition strips carrying more than ten amperes before melting shall be used, unless provided with contact surfaces of some harder metal having perfect electrical connection with the fusible part of the strip. On any combination fixture, no group of lamps requiring a current of seven amperes or over shall be ultimately dependent on one cut-out. But there shall be a cut-out to each pendant and fixture.

32. Switchboards and cut-outs should be made of incombustible material, and arranged so that there will not be any leakage of electricity across them. They should be put in places not liable to contact with foreign substances, nor exposed to moisture.

33. All switches except those in lamp sockets should be double-pole.

They must have a firm and secure contact that will make and break readily, and that will not stick between "full on" and "off," nor get out of repair easily in other ways. The points of contact must not be allowed to scrape, or rub, the entire surface of an insulating material between the contact strips; an air space must intervene. The carrying capacity of the different parts must be sufficient to prevent heating.

Fixture Work.—34. In all cases where wires are concealed within or attached to fixtures, the latter must be insulated from the gas-pipe by some approved device.

When holes are drilled in fixtures, all burs or fins must be removed from the edge of the holes before the conductors are drawn through.

When wired outside, the conductors used must be so secured as not to be cut or abraded by the pressure of the fastenings or motion of the fixture.

All wire used for fixture work must have an insulation that is durable, and not easily abraded; and must not, in any case, be smaller than No. 19 " B. & S.," or No. 20 " B. W. G."

Each fixture must be tested for possible "contact" between wire and fixture, and for "short circuit" before current is turned on.

The tendency to condensation within the pipes or fixtures should be guarded against by sealing the upper end.

No combination fixture with less than one-fourth inch clear space between the inside pipe and the outside casing will be approved.

Pendants and Sockets.—35. Cord pendants must be composed of stranded wire, and protected by rubber bushings, or something equally good, where they enter the socket.

When exposed to weather, or used in wet rooms, care must be taken to keep moisture from the inside of sockets.

The weight of every socket and lamp suspended by a cord must be borne by a ceiling block, rosette, or cleat, and by a knot under the bushing in the socket, in order to take all strain from the joints and binding screws.

Flexible cord must not be used except for pendants, wiring of fixtures and portable lamps.

Secondary Generators or Converters.—36. Converters must not be placed inside of any building except central stations, and should be inclosed in a metallic or non-combustible case. They may be placed on the outer walls when in plain sight and easy of access, but must be thoroughly insulated from them. If placed on wooden walls, or the woodwork of stone or brick buildings, the insulation must be fire-proof. When an underground service is used, the converter may be put in any convenient place that is dry and does not open into the interior of the building; this location must have the approval of the inspector before the current is turned on.

37. If for any reason it becomes necessary that the primary wires leading to and from the converter should enter a building, they must be kept apart a distance of not less than 12 inches, and the same distance from all other conducting bodies.

38. Safety fuses must be placed at the junction of all feeders and mains, and at the junction of mains and branches when necessary; also in both the primary and secondary wires of the converter, in such manner as not to be affected by the heating of the coils. Secondary wires, after leaving the converter, will be subject to rules already given for inside wiring for incandescent lighting.

The secondary circuit may be provided with a film cut-out, which connects to the earth outside of the building; but permanently grounding the secondary circuit is unsafe and will not be sanctioned.

Foreign Wires.—39. No foreign wires of any kind shall be attached to buildings insured by this company, for the purpose of carrying electric currents across the yard to any point.

40 All electric wires which may be required by the insured shall enter the premises at one point, preferably near the headquarters of the night watchman, where they can be kept under supervision; each of said wires shall be guarded by a protector against strong currents, operating by opening the circuit, and by a lightning arrester.

41. Such protectors against strong currents shall be located in a dry, accessible place inside the building, and as near the point of entrance of wires as possible, and shall be without ground connection; such protectors shall be mounted on non-combustible and insulated supports, which shall be provided with a receptacle for the burning or melted parts of such apparatus.

42. The lightning arresters on all wires must be placed between the protector against strong currents and the electrical portion of the apparatus within the building to which such wires are connected. No ground wires for such lightning arrester shall be attached to gas pipes within the premises of the insured.

43. All electric wires which may enter the premises of the insured must be insulated between the line wire on the insulator attached to the buildings outside and the protecting device within, with the best quality of water-proof insulation. Moreover, such wires must enter at a distance of not less than three inches from any other wire or any conducting material.

44. If any wires carrying high tension or strong currents are to be carried over or under other wires on the property of the insured, they shall be attached to poles so near to each other, with one wire so far above the other, that if a break should occur, the pendant wire between these poles may not be long enough to come in contact with the wire below, or, if not carried on poles, these wires shall be so placed or protected with guard wires as to render a contact between different wires impossible.

45. If the high and low tension systems are in use in the same yard, even when developed within the works, the wires must be kept separate, and so wide apart that no contact or cross-arc can be made.

Notice.—46. The underwriters reserve the right at any time to add to, change, or modify these rules, and to enforce such modifications, changes, etc., as shall be deemed necessary for safety; all reasonable efforts will be made to notify promptly all electric light companies of any change.

TUNNELING THE NARROWS.

A SCHEME for tunneling the Narrows between Staten Island and Bay Ridge is the latest result of Erastus Wiman's plans for the improvement of New York as a railroad and commercial center. The best line for the tunnel has been thought to be between a spot near Fort Wadsworth, about at the foot of Vanderbilt Avenue, Staten Island, to Bay Ridge. The depth beneath would be about 35 feet, and the length of the tunnel about 1¼ miles.

According to Mr. Wiman, Heman Clark, whose work on the new aqueduct is already well known, has declared the scheme for the tunnel to be thoroughly feasible. The character of the river bed so far as known consists of a soft soap-stone, firm and trustworthy for the necessary strain, but easily worked. There would be two lines of tunneling, parallel and close together. Mr. Wiman thinks that $5,000,000 would easily cover the entire cost.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

For works for which proposals are requested see also the "Proposal Columns,' pages i-ii-175.

WATER.

For Additional Water Items see Proposal Columns.

NEW BRITAIN, CONN —The water supply of this place is to be improved by laying an additional main from Shuttle.

ELGIN, ILL.— Important steps will soon be taken towards improving the local water-works system.

NEWMANSTOWN, PA.—The citizens of this place are uniting in favor of establishing a system of water-works.

IPAVA, ILL.—This place is to have water-works.

OXFORD, TENN.—Reports say that a petition is being circulated for signatures asking the Board of City Commissioners to order an election on the question of borrowing $50,000 for a system of water-works.

FROST, TEX.—The projected system of water-works for this place will probably be established at an early day. For particulars address J. H. Galbreath, as above.

SCOTTDALE, PA.—Reports say that the difficulties existing between the officials and others regarding the projected water-works have been overcome, and it is probable that the system will be established soon.

STATESVILLE, N. C.—Town Clerk E. B. Stimson writes: "The Board of Aldermen met August 4, and ratified a contract, made by a special committee on water-works, with L. W. Cox, of Washington City, for a system of water-works, at an annual rental of $2,000, payable semi-annually."

MASON CITY, IOWA.—Improevments are to be made to the local water-works plant.

ROCKVILLE, CONN.—At the recent meeting of the Common Council it was represented that the water protection against fire was very poor, and a committee was appointed to look up the matter and report suggestions as to what action was necessary.

CALAIS, WASH.—A complete new system of filtration is to be added to the plant of the Calais Water Company.

GALLIPOLIS, O.—The Board of Trade Committee, having in charge the project of establishing water-works here, has sent out 100 slips of inquiry to towns of equal size. The object is to ascertain whether the works should be constructed by private or public enterprise, and the actual cost of fire protection alone.

WELLSTON, O.—The people of this place have decided in favor of establishing a system of water-works.

JERSEY CITY, N. J.—Reports say that the Water Board has contracted with the Hackensack Water Company for a water supply.

GATESVILLE, TEX.—A water-works plant is to be established at this place by the Gatesville Water Supply Company, J. W. Sanders, Secretary

OPELIKA, ALA.—The people of this place have decided in favor of establishing a system of water-works, and particulars can be obtained by addressing F. M. Renfro, as above.

NAUGATUCK, CONN. — The Naugatuck Water Company has voted to increase its capital stock $5,000, and also to build a storage reservoir.

ABILENE, TEX.—Work has begun on a new artesian well. The contractors agree to bore 2,500 feet if necessary to insure a good flow of water.

PRATT MINES, ALA.—A system of water-works is to be established at this place by a newly organized company.

MINNEAPOLIS, MINN.—Important extensions are to be made to the water mains of this city. Address the City Engineer for particulars.

EAST PROVIDENCE, R. I.—The Riverside Water Company is seeking a franchise to supply this place with water, and a decision will be given at a special meeting to be held August 18.

MANCHESTER, N. H.—It is proposed to erect a high pressure reservoir on Oak Hill.

EASTPORT, ME.—The Eastport Water Company has decided to lay a main from Boyden's Lake. Materials, etc,, will soon be wanted.

MUSKEGON, MICH.—At a session of the Board of Public Works August 6, the bids for the lake work of the new water works system were found to be as follows: Thatcher & Braymen, of Toledo, all lake work complete, $52,608; Knapp & Gillen, of Racine, same work, $60,502; Dowagiac Construction Company, same work, $63,035; Moffat, Hodgkins & Co., of Syracuse, all lake work, both wells, 400 feet dock, all pipe laying, $137,000; J. C. Crowley Construction Company, bid informal. The job was let to Thatcher & Braymen.

SHELTON, WASH.—The City Council is considering the proposition to bond the city for the purpose mainly of putting in a water system for domestic and fire purposes.

STEELTON, PA. — Water-works, to cost $180,000, will, it is reported, be established at this place in the autumn.

CHURCHILL, PA.—Reports say that this place is to have a water supply.

BLOOMINGTON, IND.—Reports say that this place is to have water works, with 5½ miles of main pipe. The city is to take 60 fire plugs for 30 years, paying $45 per year for each plug, and the plugs are to throw a stream 100 feet high.

TRENTON, TENN.—The city has decided by a popular vote to issue $20,000 of bonds for the construction of water-works.

OCALA, FLA.—The election to consider the issuance of bonds to purchase the water works, which was to take place August 14, has been postponed to August 21.

YORKVILLE, S. C.—The National System of Water-Works Company, Washington, D. C., has made a proposition to construct water-works at this place.

IONA, MICH.—It is probable that steps will soon be taken by the proper officials to increase the water supply of this place.

ROCK SPRINGS, WYO.—New machinery is to be added to the local water-works plant.

GAINESVILLE, GA.—N. W. Davis, C. E., of Atlanta, Ga., writes: "I have just finished plans for a water-works system for this place. Bids will soon be opened." For details see our Proposal Columns.

PALMYRA, MO.—The Palmyra Light and Water Company has been organized at this place, and a plant will probably be established.

WYTHEVILLE, VA.—Mayor W. L. Yost writes: "The town last year built new water-works, which is supplied from Warm Spring, but are discussing the propriety of extending them to get water from another source six miles distant; main, 10,8 and 6 inches."

CORRECTIONVILLE, IOWA.—Town Clerk Henry Maennel writes: "Our town will hold a special election, August 18, for the purpose of allowing our citizens to decide whether we shall have a system of water-works."

FRANKLIN FALLS, N. H.—W. F. Daniell writes from this place as follows: "No steps have been taken as yet in regard to water-works."

GALT, ONT.—The people of this place have voted the sum of $125.000 for the purpose of establishing a system of water works.

CORTLAND, NEW YORK.—F. S. Pecke, of Watertown, Engineer for the Board of Water Commissioners, writes under date Aug. 9th: "The contract for the construction of the Water Works at Gouverneur, St. Lawrence Co., N. Y., was awarded to L. J. Richardson, of Cortland, N. Y., for the sum of $53,000, yesterday. The system will comprise about six miles of cast-iron pipe, furnished by M. J. Drummond, of New York, of the Donaldson Iron Co.'s make. Two 12" and 18½" x 11" x 18" non-condensing pumps, made by the Deane Steam Pump Co. of Holyoke, Mass. Two 60 horse-power steel boilers, made by the Phœnix Foundry and Machine Co., of Syracuse, 41 hydrants with the necessary valves of the Galvin Brass and Iron Works, Detroit, Mich. Water tower will be of steel, 30 feet diameter by 40 feet high. Water is to be taken from the Oswegatchie River, and passed through a filter, designed by the writer expressly for the requirements of the Water Commissioners. Spiral weel steel tubing will be used for the suction and for the river crossings, &c."

MARQUETTE, MICH.—A water-works system is to be established at this place at a cost of $25,000.

RICHLAND, VA.—John W. Spotts writes from here as follows: "The Richlands Water, Gas and Electric Light Company has obtained a charter, and I believe have organized. Steps will be taken at once to erect water-works, which from the proposed development of the town will necessitate a large and expensive plant, which the Company has ample means to meet. Mr. C. Graham, Pulaski City, Va., is secretary, and Mr. Wm. K. Hewson, Richlands, Tazewell, Co., Va., treasurer."

BROOKLYN, N. Y.—Commissioner Adams has forwarded a communication to Mayor Chapin, requesting that a special meeting of the Common Council be held at the earliest practicable moment for the purpose of considering and acting upon the question of improving at once the water supply of the city. The Commissioner's communication recommends the expenditure of $700,000 on additional water-mains, and $65,000 for a water tower. The Mayor has not as yet acted on the letter.

BUCHANAN, MICH. — The people of this place will hold a special election to decide the water-works question.

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Quebec, Can., Cincinnati, O.; Canton, O.; Gainesville, Ga.; New York City; Pasco, Wash.; Hoboken, N. J.; Newport, Ky.; Allegheny, Pa.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

TUSKALOOSA, ALA.—An additional brick sewer is to be established at this place. For particulars address W. W. Thompson, as above.

GRAND FORKS, DAK.—Important information can be obtained regarding extensive sewerage work in this city by addressing the City Engineer, as above.

MOUNT VERNON, O.—The city officials have under discussion the question of expending several thousand dollars on sewerage improvements.

SAN ANTONIO, TEX.—Mayor Callaghan has issued a message advocating the immediate construction of a complete system of sewers and the purchase of the water-works plant by the city.

FINDLAY, O.—Important information regarding extensive sewer work can be obtained by addressing M. G. Foster, City Clerk, as above.

QUINCY, ILL.—It is probable that a new sewer will soon be constructed in the First Ward, this city. Address Alderman Higgins, of this city, for particulars.

LINCOLN, NEB.—Numerous sewer extensions are to be made here.

FORT HOWARD, WIS.—Extensive improvements will be made to the sewerage system of this place.

MEADVILLE, PA.—The city will soon need 5 miles sewerage.

WATERVILLE, ME.—The sum of $10,000 is to be expended in extending the sewerage system of this place.

LA SALLE, ILL.—The following bids for the construction of about 25,000 feet of sewers were received by Mayor F. W. Matthiessen, August 5: Division "A."—J. P. Fox, Eau Claire, Wis, $11,942.90; John Stuart, La Salle, Ill., $15,414.02; Rockford Construction Co., Rockford, Ills., $15,873.89. Division "B."—J. P. Fox, Eau Claire, Wis., $2,493. Division "C."—John Stuart, La Salle, Ills., $4,339; J. P. Fox, Eau Claire, Wis., $5,409 20. Division "D."—J. P. Fox, Eau Claire, Wis., $7,088.40; John Cummings, La Salle, Ills, $10,900. The following contracts were awarded: Division A, B and D to J. P. Fox; Division C to John Stuart.

TORONTO, ONT.—There is a scheme on foot to establish a trunk sewer in this city. City Engineer Jennings can furnish particnlars.

LYNN, MASS.—Numerous extensions are to be made to the local sewer system.

PAWTUCKETVILLE, MASS.—Important improvements are to be made to the sewerage system of this place.

LOWELL, MASS.—It is probable that work on the Belvidere sewer will commence soon. The Chairman of the Sewer Committee can furnish details.

KANSAS CITY, MO.—City Engineer Butts has completed plans, etc., for another section of the O. K. Creek sewer. Address him, as above, for particulars.

WILMINGTON, DEL.—Numerous sewer extensions are to be made at this place. For full particulars see our Proposal Columns.

DETROIT, MICH.—Several miles of sewer mains are to be constructed in this city. For particulars address the Board of Public Works, as above.

BOSTON, MASS.—The following proposals for the construction of sections 8 and 9, Metropolitan Sewerage System (East Boston), and sections C and D (Brighton), all in this city, were opened by the Board of Metropolitan Sewerage Commissioners, August 13. Only the total figures are given. The tables in detail will appear next week.

Section 8.—National Construction Co., Boston, Mass., $60,305.25; Charles Linehan, Cambridge, Mass., $65,225; O. P. Roberts, Cambridge, Mass., $78,321; R. A. Malone & Sons, Philadelphia, Pa., $99,155.

Section 9.—R. A. Malone & Son, Philadelphia, Pa., $96,792.50; Metropolitan Construction Co., Boston, Mass., $82,348.75; O. P. Roberts & Son, Cambridge, Mass., $80,-946.25. Charles Linehan, Cambridge, Mass., $70,530; National Construction Co., Boston, Mass., $69,121.25.

Section C.—John Cavanagh & Co., Boston, Mass., $91,925; Aaron A. Hall, Dorchester, Mass., $73,109.25; National Construction Co., Boston, Mass, $64,606 25.

Section D.—Aaron A. Hall, Dorchester, Mass., $66,255.75; Charles Linehan, Cambridge, Mass., $55,225; National Construction Co, Boston, Mass, $52,546.25.

SEWERS.—See our Proposal Columns for information regarding sewer construction at the following places: Binghamton, N. Y.; Trenton, N. J.; Galion, O.; Greensboro, N. C.; Ashland, Wis.; Wilmington, Del.; Cleveland, O; Key West, Fla.; Vancouver, B. C.; Para, Brazil; Danbury, Conn.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

LOUISVILLE, KY.—A resolution has been introduced in the City Council to construct an iron highway bridge over Kentucky street at the expense of the city and the Louisville and Nashville Railroad Company.

CHESTERTOWN, MD.—It is proposed to either expend $5,000 in repairing the bridge over Chester River or replace it with an iron structure.

NEW HAVEN, CONN.—There are to be two new iron bridges built on the New Haven and Derby Road, one at Derby and the other at Ansonia. They will replace wooden structures.

Little Rock, Ark.—Mayor William G. W. Gipple writes: "The proposed free bridge across the Arkansas at this point, connecting the two sides of the city, is still merely a matter under consideration. Nothing can be done decisively until October when the County Court meets. Doubtless such a bridge will be built by the county, and commenced this fall."

Sedan, Kan.—The Lantz Suspension Bridge Company has been incorporated at this place, with a capital stock of $10,000. Address George M. Lantz, as above, for details of proposed operations.

Richmond, Va.—There is a project to erect a bridge over the river at this place. City Engineer Cutshaw can furnish information.

Trenton, N. J.—The bids for the iron work on the bridge over Bayard Pond, at Hickory Corner, ranged from $466 to $590, and for the stone work from $4 99 per cubic yard to $9.65.

Trenton, N. J.—The following bids for the erection of the iron-work of a high truss bridge, 70 foot span, 18 foot roadway, were received by Symmes B. Hutchinson, county solicitor, August 13th: Variety Iron Works, Cleveland, O., $2,185; King Iron Bridge and Manufacturing Co., Cleveland, O., $2,179; Groton Bridge and Iron Co., Groton, N. Y., $2,179; Wallis Iron Co., Jersey City, $2,211; Penn. Bridge Co., Beaver Falls, Pa., 2,247, Milliken Bros., New York, $2,300; Berlin Iron Bridge Co., East Berlin, Conn., $2,200; Dean & Westbrook, New York, $2,075; New Jersey Steel and Iron Co., N. J., $1,998. Contract awarded to lowest bidder.

Orange Grove, Ind.—It is reported that a bridge is to be erected over the Patapsco River at this place.

Apalachicola, Fla.—Reports say that Chief Engineer J. N. Cook, of the Augusta, Tallahassee and Gulf Railway, will soon let contracts for a bridge over the Ocklockonee River.

Augusta, Ga.—The sum of $8,000 is soon to be expended in building a bridge over the canal at Broad Street, this city.

Jackson County, W. Va.—Two steel bridges are to be erected in this county. Address the Clerk of the County Commissioners for particulars.

Lake Temiscamingue, Can.—Surveys are being made for a proposed bridge over the Ottawa River at the foot of Lake Temiscamingue. The clerk of the Department of Public Works can furnish particulars.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: Toledo, Wash ; Montgomery, Ala.; Beeville, Tex.; Newport, Ky.; Rome, N. Y.; Marble Falls, Tex.; Prineville, Ore.; Steubenville, O.

NEW DEPOTS.

Norfolk, Va.—Car shops, to cost $200,000, are to be erected, in this city by the Norfolk and Western Railroad Company.

Jersey City, N. J.—The Pennsylvania Railroad Company will erect a new depot and sheds at its terminus in this city at a total cost of $1,500,000.

Milwaukee, Wis.—Reports say that the Milwaukee Belt and Terminal Company will erect an extensive depot in this city.

Perth Amboy, N. J.—Reports say that the Reading Railroad Company has secured an independent outlet to new York harbor, and that the site for the new terminal is situated on the New Jersey site of the Arthur Kill, near this place. Two large coal shipping piers, extending 700 feet from the shore line; a commodious freight and storage yard, comprising 24 tracks, each of 1,500 to 2,000 feet in length, and facilities for handling coarse freight of all kinds will be provided. A branch line of railroad 18 miles in length, to connect Bound Brook with the terminal yard and the Perth Amboy piers, will also be constructed.

STREET-WORK AND PAVING.

Alexandria, D. C.—Extensive improvements are to be made to the roads throughout the county, and operations will commence at once.

Dennison, O.—The bids for paving and sewering Grant and Fourth Streets were opened August 8, and were rejected, on account of being too high. New bids will be asked for.

Lincoln, Neb.—The City Council has authorized the paving of numerous streets, and proposals will soon be wanted.

Mount Vernon, O.—Extensive paving operations are contemplated at this place.

Hannibal, Mo.—Considerable paving is to be done in this city.

Keokuk, Iowa.—The officials of this city have decided to pave numerous of the public streets with hard brick.

Brooklyn, N. Y.—The Charities Commissioners are preparing estimates for the macadamising of five miles of road at the County Farm at St. Johnland.

RAILROADS, CANALS, ETC.

Ottumwa, Ia.—This town has voted to issue bonds in the sum of $35,000 to aid in building the C., Ft. M. and D. M. Railroad.

GAS AND ELECTRIC-LIGHTING.

McKeesport, Pa.—The plant of the Union Gas Company will be considerably extended.

Wooster, O.—The Wooster Electric Light Company has decided to make extensive improvements and extensions to its plant.

Orangeburg, S. C.—The people of this place have decided in favor of electric lights and a plant will be established soon.

Newton, Iowa.—This city will pay $13,000 for an electric light plant of 1,000-light capacity, which it is to own and operate.

Richmond, Va.—The Craylor Electric Light Company has been incorporated here with a capital stock of $100,000, for the purpose of establishing an electric light plant, selling electric motors, etc. President, A. W. Barber.

Shelbina, Mo.—The people of this place have voted the sum of $5,000 to be expended in establishing an electric light plant,

Abilene, Kan.—The Mosher Arc Lamp Company has been incorporated here with a capital stock of $50,000. Incorporators, J. A. Mosher and others.

Peabody, Mass.—At a special meeting of the officials, the town accepted the report of the Electric Light Committee, and voted to establish a town plant. Thirty thousand dollars was appropriated, and a committee was appointed to carry out the vote.

West Toronto Junction, Ont.—There is a project here to expend the sum of $15,000 on an electric lighting plant.

Pelham, N. Y.—The Pelham Bay Park Electric Light, Power and Storage Company has been incorporated here, with a capital stock of $10,000. Incorporators, George W. Cochran, Edward S. Becker, and others.

Williamette, Ore.—The Falls Electric Light Company, of this place, will increase the capacity of its plant by the addition of 1,500 incandescent and 100 arc lights.

Watertown, Wis.—The local electric light plant is to be extended.

Franklin Falls, Pa.—The business men of this place have formed a syndicate for making a proposal to furnish electric lights to the town.

Winchester, Tenn.—An electric light plant is to be established at this place.

Crafton, Pa.—A company has been incorporated for the purpose of establishing an electric lighting plant at this place.

Seattle, Wash.—The Metropolitan Electric Company has been incorporated here, with a capital stock of $3,000,000. Jacob Furth, A. B. Stewart, J. M. Thompson and others, incorporators.

Uniontown, Pa.—The Uniontown Light and Heat Company of this place contemplates putting in a large arc dynamo in the new gas plant building when it is completed.

Topeka, Kan.—The Johnson Fuel and Gas Company has been incorporated here, with a capital stock of $200,000. C. P. Baker and others are incorporators,

Electric Railways.—New electric railways will be built and improvements will be made to those already established at the following places: Fall River, Mass.; Savannah, Ga.; Cincinnati, O.; New Orleans, La.; Amsterdam, N. Y.; Austin, Tex.; Dundas, Ont.

BIDS OPENED.

Brooklyn, N. Y.—Neils Pedersen has been awarded the contract for the carpenter work on the new school house at Richmond Hill, at $7,883, and the contract for mason and brick work has been awarded to Thos. W. Styles, at $7,295.

Brantford, Can.—The contract for the erection of the new Central school house was awarded to Shultz Bros., at $38,744, and the contract for heating to Smead, Dowd & Co., at $3,840.

GOVERNMENT WORK.

Washington, D. C.—The following proposals for the work specified were opened on the given dates by the Supervising Architect of the Treasury Department :

Charlotte, N. C.—Plumbing of the United States Court House, Post Office, etc., opened August 7. Bidders: C. Bargamin, Buena Vista, Va., Perfection closet, $2,960, John F. Dalton, Chicago, Ill., Delta closet, $3,107; Shanks & Burrett, Richmond, Va., Inodora closet, $2,165; Crook, Homer & Co., Inodora closet, $4,121.02; J. E. Finsley, Charlotte, N. C., Perfection closet, $2,291.

Houston, Tex.—Extension of the United States Court House and Post Office at this place, opened August 8. Bidder: William Williams, $7,330.

INDUSTRIAL.

St. Paul, Minn.—The Ways and Means Committee of the Board of County Commissioners has reported adversely on the proposition to pay $9,000 for a system of steam regulators for the city hall.

Aransas Pass, Tex.—Russell B. Harrison and others are interested in a new company called theAransas Pass and Harbor City Improvement Company, with headquarters at Topeka, Kan., organized for the purpose of building a city and improving the harbor.

Hot Springs, Ark.—The Jamestown Mining and Milling Company has been organized at Little Rock with E. A. Shipley President, and will build smelter works here.

PROPOSALS.

(Continued from page ii.)

NEW COURT HOUSE.

Notice to Contractors.

SEALED PROPOSALS WILL BE RECEIVED by the Commissioners appointed for the purpose by the County Court of Monongalia County, W. Va., at the office of the Clerk of the Circuit Court, in Morgantown, in said county, until 12 o'clock, noon, of MONDAY, September 1, 1890, for the labor and material and the construction and completion of a Court House at MORGANTOWN, WEST VIRGINIA, in accordance with the drawings and specifications furnished by John C. Fulton, architect, copies of which may be seen at this office.

First—All bids must be made upon the printed forms, to be obtained from this office, in a sealed envelope, directed to the undersigned, and marked "Proposals for Court House at Morgantown, W. Va."

Second—As an evidence of good faith every proposal shall be accompanied by cash or certified checks to the amount of three hundred dollars ($300), made payable to the County Court of Monongalia County, in case the successful bidder shall fail, for ten days after an award, to execute the required contract and bond for the faithful performance of the terms of the contract. The checks of unsuccessful bidders will be returned to them immediately after the contract is awarded or all bids rejected.

Third—The right is reserved to reject any and all bids.

Fourth—Bidders are requested to be present at the opening of proposals.

Morgantown, on the Monongahela River, may be reached by Baltimore and Ohio Railroad or from Pittsburg by daily line of steamboats.

R. E. FAST,
12 Secretary of Commissioners.

LEVEES, Port Allen, La.—Proposals are wanted until September 1, for the construction of numerous levees. Address T. G. Sparks, President Board of Levee Commissioners, as above.

BUILDING AND HEATING, Waltham, Mass.—Proposals are wanted until August 20, for the erection of a police station and court house, also steam heating and plumbing of the same. Address Hartwell & Anderson, No. 68 Devonshire Street, as above.

BRIDGE, Rome, N. Y.—Proposals are wanted until August 25, for the completion of the abutments of the bridge over the Erie Canal at this place. Address John Pugh, Highway Commissioner, as above.

BRIDGE, Marble Falls, Tex.—Proposals are wanted until August 25, for the construction of a bridge over the colorado River at this place. Structure to be 860 feet long, 50 feet high and 18-foot carriage track. Address Louis G Hester, C. E., Texas Mining and Improvement Company, as above.

PROPOSALS.

STREET PAVING.

SEALED PROPOSALS WILL BE RECEIVED for furnishing the materials and laying about 4,750 square yards of GRANITE BLOCK PAVING at the office of the Board of Road Commissioners of the city of Waterbury, City Hall, until 2 P. M., August, 20, at which time and place they will be publicly opened and read.

All bids must be upon proper blanks and must be accompanied by a bond for $300, with satisfactory sureties, conditioned for the execution of the contract within five days after notice of its award.

Certified checks for $300, payable to the city of Waterbury, to be deposited with the Board of Road Commissioners, will be received in place of the above bond.

Specifications can be seen at the City Engineer's office, at which place blank forms of proposal can be obtained as well as further information.

By order of the Board of Road Commissioners.

F W. WHITLOCK,
11 Acting City Engineer.

BUILDINGS, Portsmouth, N. H.—Proposals are wanted until September 1, for the construction of sick quarters. Address J. Mills Browne, Surgeon-General, Chief of Bureau, U. S. A., as above.

WATER PIPE, Canton, O.—Proposals are wanted until August 25, for furnishing the following quantities of iron water pipe: 35 tons 12-inch, 93 tons 8-inch, 125 tons 6-inch, 130 tons 4-inch, 20 tons 3-inch. Address Paul Field, Secretary Canton Water-Works Company, as above.

CHURCH, Roanoke, Va.—Proposals are wanted until August 27, for the erection of a stone church at this place. Address C. Ruehrmund, architect, as above.

BRIDGE, Hamilton County, O.—Proposals are wanted until August 23, for masonry superstructure of bridge over canal on Mosteller Road, Sycamore Township. Address Board of Hamilton County Commissioners.

DRY DOCK, Port Royal, S. C.—Proposals are wanted until November 1, for the construction of timber dry dock at Naval Station. Address N. H. Farquhar, Chief of Bureau of Yards and Docks.

HOTEL, Goshen, Va.—Proposals are wanted until August 27, for the erection of a brick hotel. Address Messrs. Yarnall and Goforth, 14 South Broad Street, Philadelphia, Pa.

New York av, n e cor Park pl, br dwell; cost, $16,000; o, Richard Major; a, G P Chappell; b, not selected.

ALTERATIONS—BROOKLYN.

S s Verona av, 200 E Sumner av, br asylum; cost, $13,500; o, Roman Catholic Orphan Asylum; a, F Haughton.

MISCELLANEOUS.

BOSTON, MASS.—403-05 West Broadway, 2 br mer bldgs; cost, $28,000; o, R L Barstow and E Baker; a, Winslow & Wetherell; b, Clark & Lee.

Farnsworth st, fr mfg bldg; cost, $12,000; o, Boston Wharf Company; a, M D Safford.

6-8 Hazel Place, 2 fr dwells; cost, $7-500; o, Joseph Vogel; a, Ourish & Rich.

Morton st, fr dwell; cost, $7,000; o, Ella G Hunter; a, Swanson & Murray; b, G F Murray & Co.

7 Waltham st, br apart, cost, $14,000; o, Mary M Adams; a and b, E C Heath.

25 Blue Hill av, fr dwell; cost, $7,000; o, Isabelle Davis; a, A B Pinkham.

Plans being prepared for alteration, extension and raising of old cathedral, Washington st cor Castle st, by Rand & Taylor. It is proposed to remodel for theatre.

BUTTE, MONT.—The city has voted to bond itself for $50,000 for sewers and $20,000 for a city hall.

CAMBRIDGE, MASS.—Mt. Auburn st, fr addn to church; cost, $8,000; o, St Paul's R C Church; a, P W Ford; b, A Sullivan.

Linnaean st, fr dwell; cost, $6,000; o, Mrs Anthony, a, C H Blackwell; b, A Y Currie.

Mt Auburn st, block fr dwells; cost, $7,000; o, A S Harriman; a, T B Fink; b, Sewell & Co.

Creighton st, fr dwell; cost, $4,250; o, W M Colby; b, as above.

Concord av, block fr dwells; cost, $6,300; o, J F Sullivan; a, Geo Fogarty; b, Geo Chaplin.

CANTON, O.—A 3-story business block will be erected on the northwest corner Piedmont and 8th sts. Address G D Saxton, Canton, O.

CINCINNATI, O.—A new asylum for the epileptics will be built by the State at Gallipolis. Three commissioners have been appointed to select plans and buy ground for building. J W Vance, of Gallipolis, is chairman of the commission.

2d and Broadway, alteration to br store; cost, $9,000; o, Samuel Shaw; a, Geo Vogel.

FOSTORIA, O.—A Presbyterian Church is to be erected at this place to cost $25,000. Architects Crapsey & Brown, of Cincinnati, O. Wm. Alcott, of this place, is Chairman of the Building Committee.

BUILDING INTELLIGENCE.

DENVER, COL.—Murdock bet 33d and 34d avs, br dwell; cost, $10,000; o and a, Thos Freeman.

Downing bet 19th and 20th avs, double br dwell; cost, $10,000; o, Mr Hinsell; a, Balcomb & Rice.

Broadway bet 1st and Ellsworth, br block; cost, $23,500; o, Flembing Bros; a, Miller & Janisch.

Wazee cor 17th st, bus block; cost, $100,000; o, Fledhauser & Co; a, F E Edbrooke & Co.

Lafayette bet 15th and 16th, stone dwell; cost, $35,000; o, O L Haskell; a, as above.

Downing bet 16th and 17th, br dwell; cost, $13,000; o, P D Gannons; a, as above.

13th av cor S 3d st, br terrace; cost, $10,000; o, A McAlister; a, A Dutchie.

Wynkoop bet 15th and 16th sts, br warehouse; cost, $12,000; o, Jackson & Co; a, D A Cole.

DETROIT, MICH.—Gratiot av, 2-story br schoolhouse; cost, $30,000; o, Board of Education; a, Geo C Oldfield.

Russell, High and Windsor sts, fr market; cost, $25,000; o, City of Detroit; a, Wm Voigt, Jr.

N w cor Grand River av and Perry st, 8 2-story br stores; cost, $20,000; o, Joseph Perrien; a, Hess & Raseman.

W s 4th st near Cherry st, 2½-story br residence; cost, $7,000; o, Robert Bell; a, Harry J Rill.

N s Alexandrine av, bet Woodward av and John R st, 2½-story br residence; cost, $7,000; o, John J Alley; a, A C Varney & Co.

N e cor Palmer av and Beaubien st, 2-story br residence, cost, $7,000; a, Scott, Kamper & Scott; b, W H Hollands & Son.

ERIE, PA.—A $20,000 building will be erected here. For details address J T Steen, architect, 36 6th st, Pittsburg, Pa.

INDIANAPOLIS, IND.—The Catholics of this city will erect a cathedral at a proposed cost of nearly $250,000. A bishop's residence will also be built, to cost $25,000. Bishop Chatard, of Indianapolis, can give information.

LANSFORD, PA.—Ricey, fr church; cost, $7,700; o, English Cong; a, W D Hill; b, contract not let.

MEADVILLE, PA.—East Pine st, hospital; cost, $10,000; o, Sisters of Charity; a and b, W E Morrison.

MEDIA, PA.—An annex to the court house at this place will be erected at a cost of $40 000. Address City Clerk, as above.

MILWAUKEE, WIS.—Kinnekinnic and Lincoln avs, storehouse; cost, $7,000; o, Aug Hermes; a, B Kolpacki; b, E Stollenwerk.

Prospect av, dwell; cost, $15,000; o, Marcus Cohen; a, Ferry & Clos.

MINNEAPOLIS, MINN.—2642 Portland av, fr dwell; cost, 8,000; o, C C Whitney; a, O M Barber.

Main st and 1st av S E, alterations; cost, $10,000; o, Minneapolis Ind Expos; a, C F Struck.

9 E 17th, br block of flats; cost, $26,000; John B Long; a, L Jepron.

Lake Cemetery, br chapel and vault; cost, 20,000; o, Lakewood Cemetery Asso; a, C C Yost.

2401 S Irving av, br and s dwell; cost, $16,000; o, a and b, J S O'Donnell.

NASHVILLE, TENN.—Market, 5-story br bldg; cost, $20,000; o, Craighead; a, Desmukes; b, Ed Laurent.

Church, 2-story store and office bldg; cost, $25,000; o, Dr Noel; a, Thompson & Gibel; b, S H Bowen.

Market st, 6-story s bldg; cost, $24,000; o, Craighead; a, same as above.

Sumner st, 5 s bldgs; cost, $10,000; o, Jesse French; a, Jno Lewis.

Broad and McSemne, church; cost, $40,000; o, Christ Church.

Cherry st, 6-story restaurant and hotel; cost, $25,000; o, M M Gardner; a, H C Thompson.

BUILDING INTELLIGENCE.

NEWCASTLE, WYO.—Conover & Porter, of Madison, Wis., have prepared plans for a brick school house at this place, to cost $10,000.

PALESTINE, TEX.—R C Church, gothic; cost, $25,000; o, Rev J Thion, pastor; a, N J Clayton & Co; b, not let yet.

PHOENIXVILLE, PA.—A $15,000 res will be erected here by Ernest Knapp.

POTTSTOWN, PA.—Hill School bldg; cost about $30,000.

PROVIDENCE, R. I.—Taylor and Comstock av, 2 fr ten dwells; o, Mrs Herbert West; a, Gould & Angell; b, Robert Paterson.

Westminster st, alterations and additions to Merchants' National Bank; a, Gould & Angell; b, Cutting & Bishop.

Stimson av, fr dwell; o, Mary Jackson.

Melrose st, fr and br dwell; o, Fred E Field.

Lexington av, fr dwell; o, Louise M Hopkins; a, Gould & Angell.

SEDALIA, MO.—L C and W M Buckley, architects, of St. Louis, will make plans for a $40,000 business block.

SIOUX CITY, IOWA.—N w cor Pierce st, fr dwell; cost, $8,000; o, E E Selsmer; a, J P Martin; b, not let.

2d and 3d sts, Union station; cost, $250,000; o, railroads; a, sketches made not decided.

SPRINGFIELD, ILL.—Charles F May, architect, St Louis, Mo, has completed plans for a theological college for the German Lutherans, to cost $30,000, and be heated by steam.

ST. LOUIS, MO.—Page and Prairie avs, br dwell; cost, $8,500; o, Mrs E Jones; b, J H Keefe.

Cates and Clara aves, br dwell; cost, $8,000; o and b, T C Higgins.

Lindell and Taylor aves, br dwell; cost, $12,000; o, Mrs R Jacoby; b, Goesse & Remmers.

N w cor Grand and Finney aves, br dwell; cost, $10,000; o, E Pugnet; b N Pelligreen.

15th and Gratiot sts, br machine house; cost, $7,500; o, Laclede Gas Co; b, F C Bonsack & Co.

Grand and Cook aves, br dwell; cost, $8,000; o, Dr. Hall; b, N Pelligreen.

N e cor Washington and Jefferson aves, br store and dwell; cost, $90,000; o, Ills Dairy Co; b, G W Pipe.

28th and Locust sts, br dwell; cost, $35,000; o, G M Maverick; a, Peabody & Stearns.

Francis st and Clifton Place, br dwell; cost, $7,000; W D Grant; b E B Scott.

McB Elfatrick & Sons, architects, have prepared plans for a new theatre for M Kaufmann.

ST. PAUL, MINN.—The Board of Education took out a permit for the construction of a 2-story school house on Jenks st, bet Edgerton st and Payne av (Arlington Hills District), to cost $30,000.

E 4th st, nr Minnesota st, 4-story br office bldg; cost, $30,000; o, H Broadbent.

Fairmont st, nr Dale st, 3-story stone and br dwell, cost, $12,000; o, F B Kellogg.

TERRE HAUTE, IND.—S. Hannaford's Sons, of Cincinnati, O., have the plans under way for a passenger station at this place, for the Vandalia Railroad, to cost $100,000. A freight depot and the passenger train sheds are estimated to cost $150,000 additional. Pressed brick and brown stone will be the material used.

WILMERDING, PA.—A $20,000 depot will be erected here by the Pennsylvania Railroad Co.

BUILDING.—There is nothing over $7,000 in value to report at the following places: Charleston, S. C.; Clinton, Iowa; Geneva, N. Y.; Harrisburg, Pa.; Galveston, Tex.; Worcester, Mass.; San Antonio, Tex.; Denison, Tex.; Pottsville, Pa.; Springfield, Mass.; Montclair, N. J.; Dayton, O.; Braintree, Mass.; Ogdensburg, N. Y.; Baltimore, Md.; Findlay, O.; Topeka, Kan.; Madison, Wis.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22. NUMBER 12. } PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.

NEW YORK, AUGUST 23, 1890.
LONDON, SEPTEMBER 6, 1890.

SINGLE COPIES, TEN CENTS.
Subscription, $4.00 per year in advance, post paid. } IN AMERICA.
Subscription, 25s. per annum in advance, post paid } IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING,

TERMS, $4 PER YEAR, IN ADVANCE.

25*s*. in GREAT BRITAIN. Other Foreign Countries $6.

Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $6; China, Japan, Sandwich Islands, Mexico and Cuba, $6; South America, $6.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

A LESSON FOR BUILDING DEPARTMENTS.

THE letter which was published in THE ENGINEERING AND BUILDING RECORD of last week regarding the defective trusses in Herrmann's Theatre now being erected in Brooklyn, elicited very general comment from the daily papers of that city and those of New York, and the public attention thus drawn to the matter has caused the owner to suspend work on the building until the defects are remedied or some more satisfactory method of construction devised. Meantime we have received another letter from the same source, showing the danger to be even greater than at first suspected, which has been more than corroborated by an investigation made by our representative, and, in the opinion of Building Commissioner Platt, the defective trusses will probably be removed.

This might be the end of the matter, and a very satisfactory one as far as this particular building is concerned, or as we are concerned with it through our correspondent's letter, but the facts brought out in the course of this discussion and investigation, coupled with a letter published in this issue from another Brooklyn correspondent, also a well-known civil engineer, who has been in charge of important work in New York and Brooklyn, indicate that there is something seriously wrong in the Brooklyn Department of Buildings.

The duties of such a department are twofold; first, to see that no building is undertaken until satisfactory plans for it have been approved; second, to see that the building is erected in accordance with those plans and the regulations of the department. The first requires the careful examination of the plans by some one thoroughly conversant with the mathematics of stresses and strength of building materials and also with the requirements of good modern construction. Either there is no such person in the Brooklyn Department or he has greatly neglected his duty in regard to the plans of the building in question. What other explanation can there be of the statement by the Commissioner, that the floors were figured for a load of 120 pounds per square foot, when a very simple calculation shows that that load would probably be sufficient to break the tie rod of at least one of the supporting trusses even if no weight were transmitted to it from the floor above by the intervening partition? The inadequacy of the cast-iron columns supporting the steel beams is another illustration of the same thing, and the slipshod way in which they have been set up indicates gross neglect in the inspection of the work after the plans had been approved. Even the plain provisions of the Brooklyn Building Law regarding cap and bond stones in the walls under such pillars have been entirely disregarded, and instead of a cut stone 8 inches thick and 24 inches long, as required, there is a bit of blue-stone about 4 inches thick and 20 inches long, on one end of which the pillar sets, while the bond stones are entirely omitted.

It seems as if the most probable cause of these shortcomings on the part of the Building Department is the inadequacy of the appropriation for its work. This for the current year is $39,000, out of which must be paid $3,000 to the Commissioner, and $1,500 to each of 17 or 18 inspectors, besides a deputy commissioner and clerks. This force has to keep track of some 5,000 buildings per year, aggregating in value $25,000,000 or $30,000,000; which, allowing them to average four months in construction, would mean that about 1,700 buildings are constantly in course of erection, giving each inspector about 100 buildings to look after, even supposing operations to be conducted uniformly throughout the year.

It is obviously out of the question for any one man to properly keep track of 100 buildings at once, and this may, in a measure, account for such oversights as have been mentioned, while it, of course, does not justify them. Another reason is the increasing number of heavy buildings that are being erected in the city. Until recently Brooklyn was largely a city of residences, and, except for an occasional church or warehouse, almost all her new buildings were dwelling houses. In recent years, however, this has been very much changed, and a class of buildings is being erected there for stores, offices, public assemblies, etc., that will compare favorably for size and finish with those in most of our large cities. It is natural that the Building Department should follow, rather than lead, in such a change, and that the methods of computation and inspection which answered well enough for the regular three-story brown-stone, or even the Clinton Avenue mansion, or an occasional church, should be found sadly inadequate for the structures with which it now has to deal.

If the millions which are yearly spent in making Brooklyn a bigger and better city to live and do business in are to be wisely and safely expended, it seems very obvious that the methods of her Building Department should be thoroughly and speedily revised, and enough money appropriated to enable the Commissioner to secure the services of a sufficient number of competent men to make sure that all buildings hereafter erected are properly designed and carefully constructed.

EXHAUST STEAM HEATING.

IT is not so very long ago that the idea of using exhaust steam for heating was first suggested. The economy of utilizing what, with a large number of non-condensing engines, was really a waste material seemed so obvious that the matter was entered into with a good deal of enthusiasm, and many owners of power plants congratulated themselves on having placed within their reach a means of getting something for nothing. Live steam was in many instances wholly abandoned as a heating agent; in others it was retained merely as an auxiliary. There was, to use a popular trade term, a boom in exhaust steam heating.

Before long, however, there were, in many quarters, misgivings as to whether exhaust steam was really so inexpensive an article as it had been supposed to be. Strange to say the new heating agent did seem to cost something,—a good deal in some cases,—more, in fact, than live steam. At least such were the indications of the coal bills To those of an investigating turn of mind there was little mystery about the matter. It was soon found that exhaust steam had been applied under conditions which were fatal to economy. The old pipe systems which had worked very well with live steam, but which were more or less inadequate for the requirements of exhaust heating, had, in many places, been retained, with the result that high back pressures were created in the engines, and heat in the buildings was obtained at an expense of power which considerably overbalanced the calculated savings. In other cases, again, where the amount of steam required for heating was very small compared with the amount exhausted by the engine it would have proved much more economical to fit the latter with a condenser and to use live steam for heating.

Taken altogether there was abundant evidence to show that the theory of heating by exhaust steam was but imperfectly understood by many who attempted to apply it. Disappointment and discouragement were, therefore, natural results. Experience and good judgment have since led to a better appreciation of the requirements of successful exhaust steam heating, and under competent advice the system now rarely fails to give satisfaction. A good illustration of what may be accomplished by it is furnished by a correspondent, whose letter we publish in another column. The figures there given speak for themselves and tend to confirm the early impression that exhaust steam, under certain conditions, costs practically nothing. There are, however, as we have attempted to show, limitations which cannot be overstepped without giving the benefits of the system a wholly imaginary character.

WAS IT PREMATURE?

Referring to a letter received from Professor Herrmann regarding the criticisms on his new theater building, the Brooklyn *Standard-Union* takes credit to itself for having previously "published a report of an interview between his architect and Building Commissioner Platt, completely setting forth the fact that the new theater building was prematurely criticised by 'Civil Engineer' in The Engineering and Building Record, and that, when the work is completed as contemplated, it will be one of the safest of structures."

In view of what was found by our representative in his investigation of the theatre building, which is detailed on another page, it would seem that the criticism was anything but premature, and that Professor Herrmann and the public, for whose entertainment he is building, have abundant reason to be grateful to our correspondent for his timely warning.

Would the *Standard-Union* have had our correspondent wait until the structural parts of the building were concealed by the ornamental ones, or until competent authority could point out what made the building fall down rather than seasonably indicate what would make it stand up? It is easy to be wise after the event, but it takes a wise man to show where danger lies in time to avoid it, and that is the part most men prefer to play when possible.

There is no reason to doubt that Professor Herrmann intended to erect a safe and suitable building; but, in view of recent developments, it seems to be very doubtful whether his expectations would have been realized had not a man trained to critically observe such matters chanced to note the structural defects of the new building and taken the trouble to call public attention to a matter of public concern. It would be well if this were done oftener.

THAT DANGEROUS TRUSS WILL COME OUT.

As we go to press we learn that Professor Herrmann has ordered the removal from his new Brooklyn theatre building of the floor truss, to whose faulty design attention was called by "Civil Engineer" in our last issue.

DISINFECTING CANDLES.

Of late, owing to its proved germicidic power, the vapor of bromine has come to the front as a disinfectant. According to *Industries*, the bromine is converted into the organic bromine compound dibromonaphthalene, an almost inodorous substance, and this is dissolved in any desired quantity in the fat or wax, before it is run into the molds. The result is a candle or night light which in shape and appearance resembles an ordinary candle or night light, but differs from it in this respect, that when burnt it produces free bromine vapor, at the same time emitting the usual amount of light. The night lights are put up in hygienic iodine night lights and candles which, on burning, liberate iodine vapor in any required quantity, in the same manner as the bromine night lights liberate bromine, and are made in a similar way.

FLOATING THE OHIO CONNECTING RAILWAY CHANNEL SPAN.

The Ohio Connecting Railway, about 13,000 feet long, is essentially a belt road built chiefly as a transfer between north and northwestern and south and southwestern railroads at Pittsburg, and includes a bridge 4,558 feet long across the upper part of Brunot's Island and the Ohio River, a little below Pittsburg, Pa.

The channel span of this bridge is a steel single track through single intersection span with intermediate subpanels and members. The trusses are 25 feet apart and have a maximum depth of 65 feet. They are 523 feet long and have curved top chords. The masonry piers are about 80 feet high and between them an enormous river traffic of steamboats, barges and rafts constantly passes. To avoid obstructing this traffic, as well as to be somewhat less exposed to danger from flood, it was decided not to build any false work, trestles or piling whatever between the piers, but instead to assemble the span at the required level, with its axis perpendicular to the final position and far enough removed to be clear of the main waterway, then to float it to its required position and secure it to the abutment seats.

In the shallow water along the shore of the island piles were driven on which to erect the false work and span. The piles were driven in an area of about 100x600 feet, the short side of the rectangle about parallel to the line of the bridge and 300 feet below it at the upper end. The piles were arranged in rows corresponding to the panel of the bridge. Each row was cut off and capped about 13½ feet above normal water level, and several lines of 20-inch steel I beams were laid across the caps. These formed stringers on which timber trestle bents, 54 feet high and 90 feet wide at the bottom, and 30 feet at the top, were erected and secured by wooden bracing and special adjustable iron tie rods.

On this false work the iron and steel bridge members were hoisted, assembled and connected in the usual manner from a traveling wooden erecting tower nearly 100 feet high. This part of the work was rapidly executed in 15 working days. Nine specially constructed barges were then floated into position under the 20-inch steel beams, and between the rows of piles. The barges were 130'x25'x8' deep, strengthened by longitudinal and transverse bulkheads, and contained inlet valves through the bottom of every chamber. These valves were opened and the barges submerged sufficiently to pass under the steel beams. The valves were then closed, and on August 18 the water was pumped out in about five hours by steam pumps on three adjacent tug boats, and as the barges rose they finally received the entire weight of the bridge span and supporting false work and floated it clear above the piles.

The false work was securely connected and braced to the barges, which were connected together by longitudinal timbers and temporarily bolted with iron plates to the piles. Decked barges were secured to the others and to the false work at the ends, and carried four multiple spooled hoisting engines, besides which two others were set up on shore, all of them being supplied with about 60,000 feet of lines. The span was secured against overturning by heavy steel guy ropes from each end of each barge, and on the morning of August 19 guy ropes were attached to the floating mass, the barges disconnected from the piles and the hoisting engines, winding upon tackles made fast to the shore, slowly drew the barges clear of the piles. Stringers across the rear of the barges and extra braces were then placed where the piles had previously interfered and the barges and their burden again drawn forward, swung through an angle of about 90 degrees and drawn up stream between the bridge piers which had about 25 feet clearance from the end barges. The movement was very slow, occupying several hours, and was always in very short stages, preceded by careful adjustment of the guy lines. The bridge was thus brought approximately to position 21 inches above the required level. Guide bolts were passed through the shoes and inserted in holes prepared in the masonry, and the valves in the barges being opened the false work gradually sunk until it deposited the span safely on its seats and left it there free and clear at about 7.30 P. M. The total weight moved by the barges was about 1,800 tons, 915 of which was the weight of the permanent span.

The bridge site is near the head of a "riffle," and the normal current is very swift there, but was, at the time of bridge launching, reduced to an estimated velocity of three miles an hour by closing the wickets of the United States Government dam across the river at Davis Island, a few miles below. The conditions were mainly favorable to the movement of the bridge, but rainy weather inconvenienced the thousands of spectators, and several times drove the workmen off and interrupted the operations. Once there was a gust of wind sufficient to accelerate the motion of the barges and strain their guys.

The false work will be removed and used to erect, in its required position, another span of the same bridge. Large spans over the Hawkesbury River, Australia, the St. Lawrence River, the Missouri River, and perhaps elsewhere, have been erected in a somewhat similar manner by the use of floating false work, but so far as we remember none of them were as long as this span, nor was the false work for them built on piles and afterwards transferred to barges, but was originally constructed on them. The Keystone Bridge Company, of Pittsburg, are the contractors for the building and erection of the bridge. C. L. Strobel is the Chief Engineer of the Keystone Bridge Company, Max J. Becker, Chief Engineer of the Ohio Connecting Railway Company, and George R. Buchan is Superintendent of Outside Construction for the Keystone Bridge Company.

We hope soon to publish detailed descriptions and illustrations, that are now being prepared, of the superstructure of this bridge and the false work, traveler, barges and general erection plant.

MAKERS OF STEAM ROAD ROLLERS.

In reply to an inquiry from Willard Beahan, Engineer of Maintenance, City Hall, St. Louis, Mo., for the names of makers of steam road rollers in the United States, we give the following: The foundry and machine department of the Harrisburg Car Manufacturing Company, Harrisburg, Pa., and W. C. Oastler, 43 Exchange Place, New York, who handles the English roller made by Aveling & Porter. Among makers of other road rollers are The American Road Machine Company, Kennett Square, Pa., and the F. C. Austin Manufacturing Company, of Chicago, Ill.

Ex-Governor Gilpin, of Colorado, is said to be now developing the railway project for the construction of a line through America and across Behring Straits into Siberia, thence through Asia and Europe to the eastern shore of the Atlantic.

PERSONAL.

William S. Bacot is the engineer of roads at Stapleton, S. I.

H. D. Ludden has been appointed City Engineer of Detroit for a term of four years from 1st July ult.

Davis & Hulbert, Fuller's Wedge Building, Schenectady, N. Y., have opened an architect's office, and would be pleased to receive catalogues and office samples from manufacturers of builders' supplies.

Col. Jedediah H. Baxter, Chief Medical Purveyor of the army, has been nominated by President Harrison to be Surgeon-General, with the rank of Brigadier-General. He succeeds General John Moore, who has been placed on the retired list, having reached the age of 64 years.

Mr. J. J. R. Croes, Chief Engineer of the Suburban Rapid Transit Company, of New York City, returned on the "Alaska" on August 3 from a tour of 12,000 miles, including the sea voyages, and extending from Edinburgh on the north to Tunis and Malta on the south, and from London, Paris and Algiers on the west to Syracuse, Vienna and Berlin on the east. Immediately on his arrival in New York he received orders to extend the Suburban Rapid Transit Road a mile, and work has already been begun on the foundations by Allston, Gerry & Co., and on the plate girder superstructure by the Wallis Iron Works.

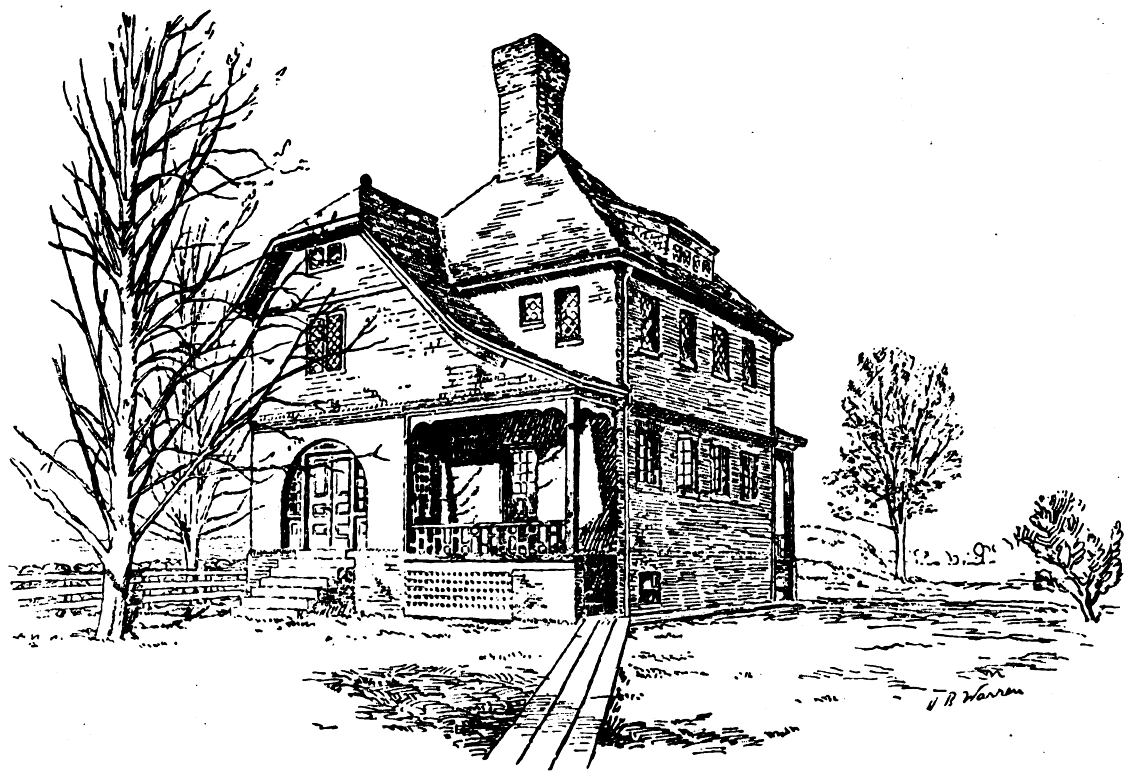
ENGINEERING SOCIETIES.

THE Civil Engineers' Club, of Cleveland, O., held a meeting on August 12, 1890, with President Searles in the chair. Sixteen members and two visitors were present. The minutes of the last meeting were read and approved. A communication from the Western Society of Engineers was received, requesting the Club to appoint a committee to meet in Chicago, on Tuesday, October 14, 1890, to aid in formulating a plan for holding an International Congress of Engineers at Chicago, in connection with the World's Fair, and the President was instructed to appoint a committee of three for this purpose.

The application for membership of George C. Lucas was received.

The President announced that the "Technischer Verein" would hold a convention in Cleveland before the next regular meeting of the Club. The Executive Board was authorized to take the necessary action to extend the courtesies of the Club to the visiting scientists.

The paper of the evening was by Jas. Ritchie on "Some Recent Constructions in Railway Bridges," but in his absence it was read by Walter P. Rice. It was followed by a discussion on the use of iron and steel in construction, of kinds of steel to be used, relative length of plate girders and latticed bridges, and the relative merits of the pin-connected and riveted bridges.



RESIDENCE OF E. A. P. NEWCOMB, ARCHITECT, BOSTON, MASS.

A CIRCULAR just issued by the American Society of Mechanical Engineers announces that the library fund accumulated for the purchase of books now amounts to upwards of $2,000. The Council have authorized the expenditure of this fund in part for such books as the profession of mechanical engineering calls for most loudly and often. The help of members is requested in deciding upon this list and the library committee invite suggestions so as to be assured that in preparing their catalogue they are acting under the advice of many who are best qualified for this duty.

THE twelfth semi-annual convention of the National Electric Light Association was held this week at Cape May, N. J.

A COMPANY is being organized at Atlanta, Ga., for the purpose of manufacturing an improved paving brick, together with ornamental and first grade building brick.

LETTER FROM ENGLAND.

(Regular Correspondence.)

LONDON, August 8, 1890.

A VERY interesting judgment was delivered in the House of Lords a few days since in the case of the Institution of Civil Engineers *vs.* the Commissioners of the Inland Revenue. The Commissioners some years since had sought to assess the Institution on an annual value of £1,619 ($7,771.20), to which the Institution, through their Secretary, Mr. James Forrest, replied, claiming exception, a claim they have maintained from year to year. The Commissioners went to the Divisional Court and obtained a judgment, the judge holding that the Institution was not exempt. From the Divisional Court Mr. Forrest went to the Court of Appeals, where Lord Justice Lopez reversed the decision, giving judgment in favor of the Institution. The Commissioners next took the matter to the House of Lords, where the case was heard by the Lord Chancellor and the Law Lords Watson and Macnaghten. In giving judgment last week the Lord Chancellor held that the Institution was not exempt, on the ground that a large proportion of its work was not pure science, but science as applied to engineering art. He held, further, that the Institution was a society founded for the advantage and in the interests of civil engineers, affording valuable and important means for their training and instruction, to the interest and advantage of the members of the Institution. The other two judges gave their judgment on the other side. Lord Watson held that the mere fact of membership being confined to those who were actively engaged and who have attained a degree of eminence in the profession did not militate against the objects of the Institution; he did not doubt that membership was accompanied by a certain amount of prestige, a prestige of some service to the individual in his professional career, but at the same time he held that there is a science of civil engineering, that its development is of the utmost consequence to our national interest, and that the Institution of Civil Engineers was founded and is maintained in the interests of that national weal.

Lord Macnaghten, in the course of his judgment, put the question at issue as follows: "Is the property of the Institution of Civil Engineers legally appropriated and applied for the promotion of the science of civil engineering, or is it legally appropriated and applied for the benefit of civil engineers in order to enable them to practice their profession to greater advantage?"

He did not doubt that the Institution had raised the standard of the profession, a fact which doubtless was advantageous to the civil engineer, but he held that that result was merely incidental to the purpose and object of the Society; he held with the Master of the Rolls that the Society does something higher than the mere education of students for the profession of civil engineering. The judgment being for the Institution by the balance of two votes to one it is, therefore, declared to be exempt from the assessment.

The Institution of Mechanical Engineers has held its meeting this year at Sheffield, and it is a notable fact that several larger works were closed to the Institution as a body, although open by special individual invitation. It is openly stated, without contradiction, that the origin of this unusual step was that a large number of foreigners, Americans, Germans and others were with the members, and that Sheffield, being strongly protectionist in its feeling, declined to exhibit to the world its special features of manufacture. Sheffield in the present as represented by the firms in question is not to be congratulated on the narrowness and smallness of its views.

IN celebrating the completion of the harbor improvements at Ciotat, the manager, M. Robert, recently gave a remarkable dinner to the press and the engineer corps. The caisson was decorated and brilliantly illuminated, and the banquet in the working chamber, at the bottom of the harbor, 26 feet below the surface of the sea. The banquet was followed by a concert, and the guests remained for several hours without any other inconvenience than the slight buzzing in their ears caused by the atmospheric pressure.

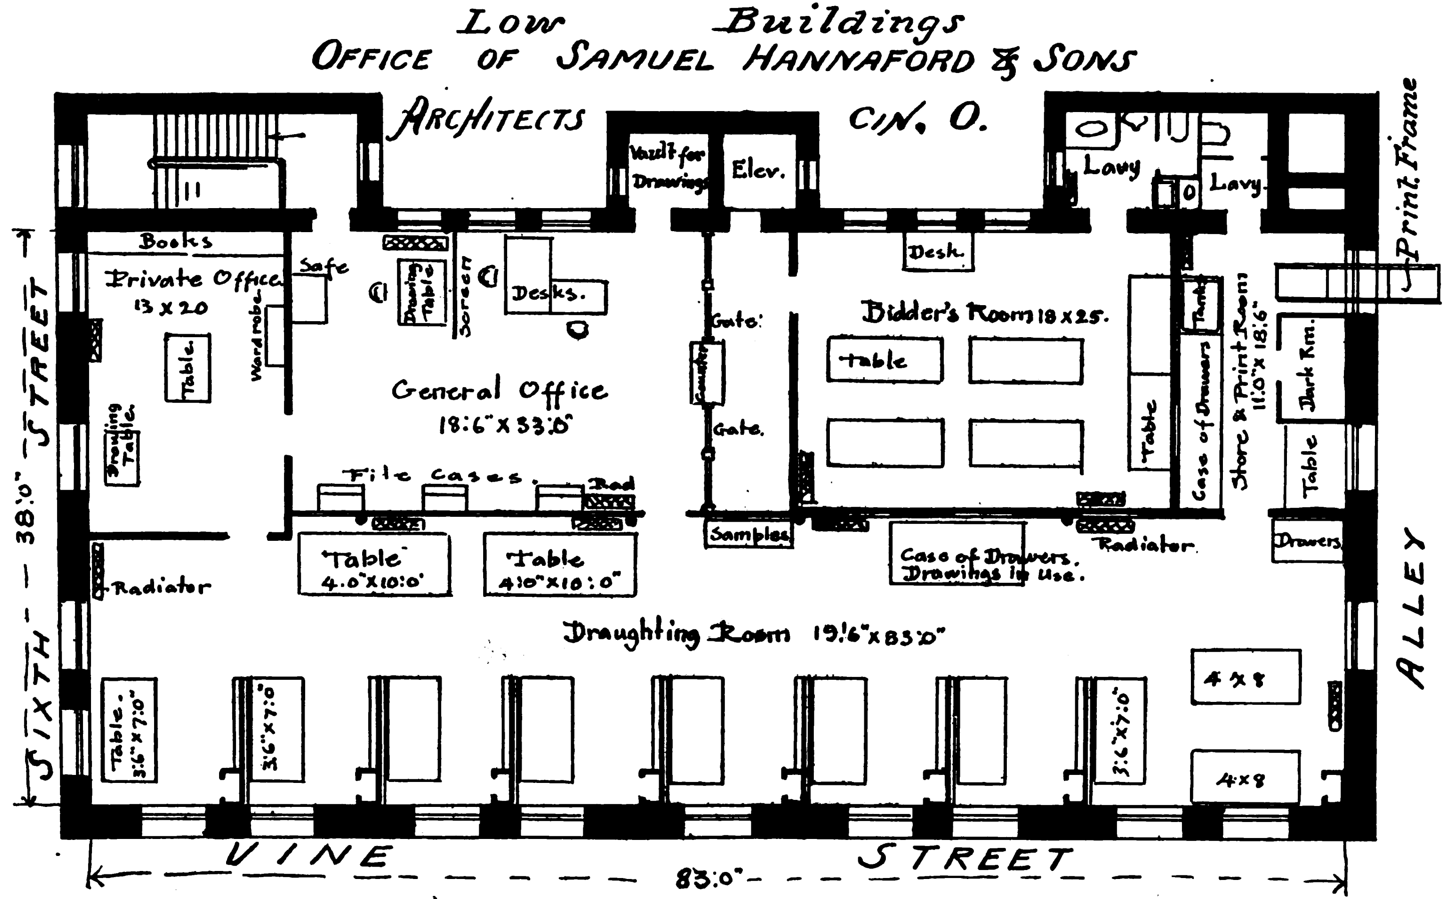
THE latest two canal projects in France are attracting much attention. One of the proposed canals is to run from Narbonne to Bordeaux, connecting the Mediterranean Sea and the Atlantic Ocean, and the other is to connect Paris and Rouen, and is thus to put Paris in direct communication with the sea. It is reported that the necessary capital has already been raised.

NEW OFFICES OF SAMUEL HANNAFORD & SONS, ARCHITECTS, CINCINNATI.

IN connection with what we have published within the past year on architects' offices,* the accompanying plan, showing the arrangement of the newly fitted office of Samuel Hannaford & Sons, architects, cf Cincinnati, O., will prove interesting. For the sketch and particulars we are indebted to Mr. Louis G. Dittor.

The office occupies the top story of Hulbert Block, corner Sixth and Vine Streets. The entrance to the elevator is by a corridor leading directly through the center of the building from the main entrance on Vine Street.

In the draughting room a dozen men can work conveniently, and in case of necessity more than twice that number can be handled without becoming uncomfortably crowded. One of the features is the convenience of the stalls, which are constructed of narrow partitions about 6 feet 6 inches high, with a projecting ledge on each side of about 6 inches, and high enough to admit of placing ordinary drawing boards under them. In the angle of partition and wall is built a neat closet arrangement—locker and drawers above, with closet below. The tables are made to raise or lower to any required height, and to tilt from a horizontal to a vertical position.



THE AMERICAN INSTITUTE OF BUILDING ARTS.

AUGUST 11 was "Inspection Day" at the American Institute of Building Arts, at Chicago. The latter, according to the Chicago *Inter-Ocean*, is conducted by the Illinois Chapter of the American Institute of Architects. In its present form it is quite a new institution, although it was established several years ago. To understand the true meaning of inspection day it is necessary to comprehend the objects of the institute as now conducted. It contains an exhibit of building materials in their manifold forms. It furnishes architects, owners, and those otherwise interested in building with information on all subjects connected with architectural construction. It is a meeting place for the chapter of architects, and has other functions as well. Inspection day has been established as a bi-monthly occasion for the meeting of architects and building contractors, manufacturing agents, and others on a common ground. It is the intention of the management to give all who are interested in building materials a chance to meet the architects of the city without the necessity of visiting the various offices. The average architect is too busy a man to spare time during his office hours to talk with those who may desire to present new ideas or materials to him for consideration, but on inspection day the contractor will be given his opportunity.

According to Mr. H. W. Perce, who is the manager of the institute, the institute has only been under its present management since last May. Previous to that time it had been merely a private enterprise, and, although successful and useful, its scope was comparatively limited. As conducted now it is an educational institution, and its aim is to advance the building arts. Its income, small or great, will always be used to extend its sphere of usefulness.

THE OCMULGEE, GA., CANAL.

IN the report recently submitted to the Macon, Ga., Canal and Manufacturing Company, on the project of bringing water to Macon from the Ocmulgee River through a 10-mile canal, Col. B. S. Church recommends a canal 50 feet wide on the top or water line, 30 feet in width on the bottom, with a depth of 10 feet of water during maximum flow, and a grade 0.528 of a foot per mile.

The above dimensions, according to Colonel Church, will convey 1,288 cubic feet per second to the vicinity of the city, which is nearly the minimum supply of the Ocmulgee River. It gives what will be required for all purposes for many years to come. In the future, when more is desired, the canal may be enlarged by a floating dredge, or, still better, a supplementary canal can be constructed on the other side of the river, giving two independent sources of supply, which is an advantage.

Then only a part of the supply would be shut off when repairs are needed.

This canal, 50 feet wide, delivering 1,288 cubic feet, and having effective head or fall of 48 feet back into the river at its lower end, will create 7,000 theoretical horse-power almost within the city limits, which equals 6,000 actual horse-power outside of the water needed for the city supply. This converted into electrical energy will produce 5,000 salable electrical horse-power.

Such command of power and water can hardly fail to attract manufacturing interests of many kinds to Macon, and give the city an unwonted impetus to growth and increase in the value of real estate.

The cost of the canal, distributing system, and power installation is estimated at $548,000.

THE formal opening of the Boynton Bicycle Railway, between Boynton Junction and Brighton Beach, Coney Island, took place last week. The cars and engines are constructed on the bicycle principle, and run over a single rail of the old road from Gravesend to Coney Island.

VILLAGE WATER SUPPLY.

THE village of Earls Barton, England, has recently been supplied with water by a scheme of which a few particulars may prove interesting.

According to accounts given in several English papers, the population is only 2,500, and the inhabitants did not wish to carry out works involving a large capital outlay or annual maintenance. Four wells have been sunk through porous strata, situate on rising ground above the village, and good water was found on the surface of a thick clay strata at a depth of 20 feet. Neither of these wells would yield sufficient in itself to supply the village, but an ample supply can be obtained by connecting the four wells together with a collecting pipe laid just below the surface of the clay. The length of the 9-inch earthenware socketed collecting pipe will be 300 yards, and it will have open joints at the top of the pipe to admit water. A 4-inch iron surface main will be connected to the end of the collecting pipe, and will convey the water to the distributing pipes in the village. The collecting pipe is sufficiently high in level to enable the greater part of the village to be supplied by gravitation. The part of the village which is too high to be supplied by gravitation has already a good supply from surface wells, but the scheme is arranged so that a small pump can be put down at any time to raise the water into a tank, which would increase the pressure sufficiently to supply this part also. The cost of the gravitation scheme to supply those parts of the village now in need of water would only be $5,500, and the annual expense would be practically nothing. If a pump and water tank is added to supply the high part of the village, the extra cost would be $2,000.

THE ROCHESTER, N. Y., WATER-WORKS.

IT is reported that a proposition to have a private company furnish water to the city of Rochester, N. Y., is under consideration. The proposition, as stated in a local paper, is to purchase the present water-works from the city at a price which will reimburse it for all expenditures for the rights at Hemlock Lake and the conduit line to Mt. Hope Reservoir, and then to contract to deliver at Mt. Hope Reservoir any amount of water the city may need up to 15,000,000 gallons per day, at 3 cents per 1,000 gallons.

THE New York Street Cleaning Department now has a fire engine to help it keep the streets clean. It has obtained from the Fire Department an Amoskeag engine, a two-wheel tender and other apparatus, to be used in flushing the streets with water, especially those on the east and west sides.

THE KINGSTON-ON-THAMES SEWAGE WORKS.

THE discharge of the sewage of Kingston, a town near London, in a crude state into the Thames involved such a serious nuisance to the population lower down the river, that the authoriites have been obliged to construct disposal works. The following account is prepared from notes furnished by our London correspondent, with additions from accounts of the same work in the *Engineer* and *Engineering*.

The Kingston sewage works have been erected by the Corporation of that borough, at a cost of about £23,000. A lease is granted to the Native Guano Company, who treats the sewage by the A B C process, and receives a subsidy equal to a rate of 3*d*. in the pound, retaining for its own benefit the "native guano" obtained from the sewage. This manurial product is stated to receive a ready sale at £3 10*s*. per ton. The works at Kingston are designed not only for the treatment of the Kingston sewage, but likewise that of Surbiton and Hampton Wick. The sewage of the last named locality is not yet under treatment, but will shortly be made available by being transferred to the works through one of Shone's ejectors, which will send the sewage over the railway bridge. Kingston has a population of 26,000, Surbiton 12,000, and Hampton Wick 2,500. The works have been designed for treating the sewage of 35,000 people, but could be enlarged, at a very moderate cost, so as to answer for 50,000. The works were designed by Major Macaulay, Borough Surveyor of Kingston, in conjunction with C. E. Robinson, M. Inst. C. E., the Consulting Engineer to the Native Guano Company.

The works, which were opened June 29, 1889, occupy a plot of land about 800 feet long by 250 feet broad, on which there has been erected a comparatively small building two stories high, which differs but little in appearance from an ordinary dwelling house, and in this building are placed the engines, boilers, pumps, mixers, filter presses, and drying cylinders required for conducting the process.

The engines were constructed by Willans & Robinson, of Thames Ditton, and are of the central valve triple-expansion type, running at speeds ranging from 350 to 550 revolutions per minute. In all there are eight engines, namely, two of 40 indicated horse-power, used alternately for driving the pug mills, revolving cylinders, etc., and six 15 horse-power pumping engines, driving centrifugal pumps of the Invincible type constructed by J. & H. Gwynne, of Hammersmith. Three of these pumps dealing with the Kingston sewage have 10-inch suction and delivery pipes, and are each capable of raising at least 100,000 gallons of sewage per hour to an average height of 10 feet. The three pumps for the Surbiton district have 7-inch suctions, and can each raise 45,000 gallons of sewage per hour to an average height of 13 or 14 feet.

Two mortar mills are used for grinding the chemicals, which are then mixed in vats and discharged into the pump well. A small centrifugal pump supplies water from the river for the boilers, mixing the chemicals, and other purposes. Either of the two 40 horse-power engines can be used for driving the mortar mills, sludge and water pumps, the drying cylinder and mill elevators.

It was originally intended to deal with the Kingston sewage only, and to use horizontal engines of the ordinary type for performing the pumping and driving the mixing and other machinery. With this arrangement an engine house, 50x40 feet, would have been required; with the eight high-speed engines above mentioned, driving a plant of nearly double the capacity of that required for Kingston alone, the engine room measures only 25x14½ feet, and sufficient space is left for the erection of an additional engine, should it ever become necessary to do so. Steam for the engines is supplied by three boilers of the locomotive type, one of 80 and two of 60 horse-power each, also constructed by Willans & Robinson. The largest of these is 12 feet 6 inches long by 4 feet in diameter, the other two being each 11 feet 6 inches long by 3 feet 6 inches in diameter; all three have been designed for a working pressure of 150 pounds per square inch, and are placed in a boiler house measuring 24 feet 3 inches by 23 feet 9 inches. One advantage of this type of boiler, in the present instance, has been that as no tall chimney stack is required, it has been possible to give all the chimneys the same shape and appearance as those of an ordinary dwelling house.

The land was the property of the corporation. The cost of the buildings and works amounted to a rate of three halfpence in the pound.

The contract for the whole of the works was let to W. Cuncliffe, of Dorking, the sub-contractors being Willans & Robinson for the engines, boilers and pumps, and Holroyd, Horsfield & Wilson, of Leeds, for the filter presses and drying cylinders.

Kingston is situated below the intakes of the London water companies, and is removed from tidal influence by the intervention of Teddington Lock. The sewage on reaching the works passes through a screening chamber, which intercepts coarse matter likely to choke or injure the pumps. Thence it proceeds through a culvert to a pump well 25 feet deep and 14 feet in diameter, under the main building, where it receives the B. C., or deodorizing and purifying mixture. This consists of clay and charcoal, mingled with a small quantity of blood. The sewage thus partially treated is raised about 12 feet by centrifugal pumps, of which there are three, each driven by a 15 horse-power engine, and capable of lifting 1,650 gallons per minute.

These pumps discharge into a meter chamber, where the sewage is measured and the quantity registered. The Surbiton sewage is separately received and screened, and is forced by centrifugal pumps through a meter into the Kingston pump well. For this purpose there are three pumps, each driven by an 8 horse-power engine, and capable of lifting 750 gallons per minute.

The sewage of Kingston and Surbiton having been alike dosed with the B. C. mixture, emerges from the

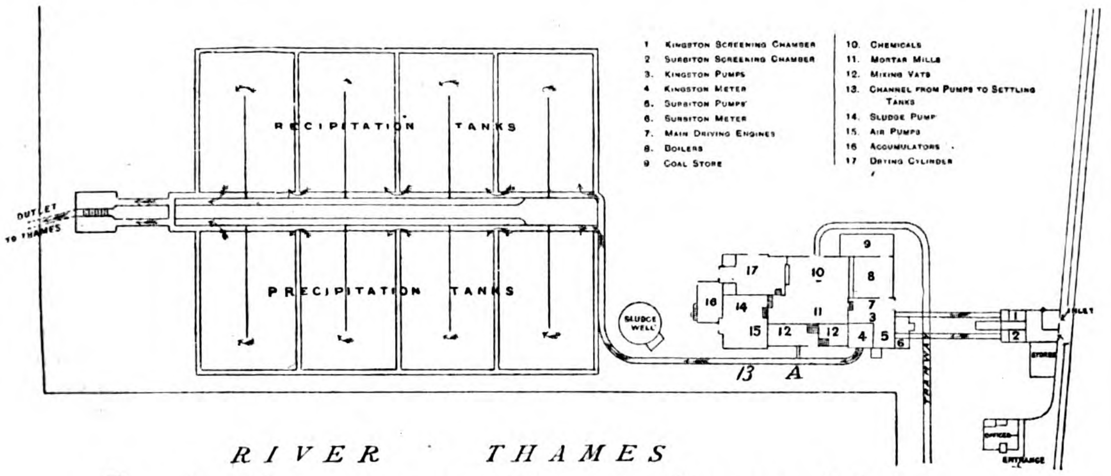

FIG. 1 KINGSTON-ON-THAMES SEWAGE WORKS

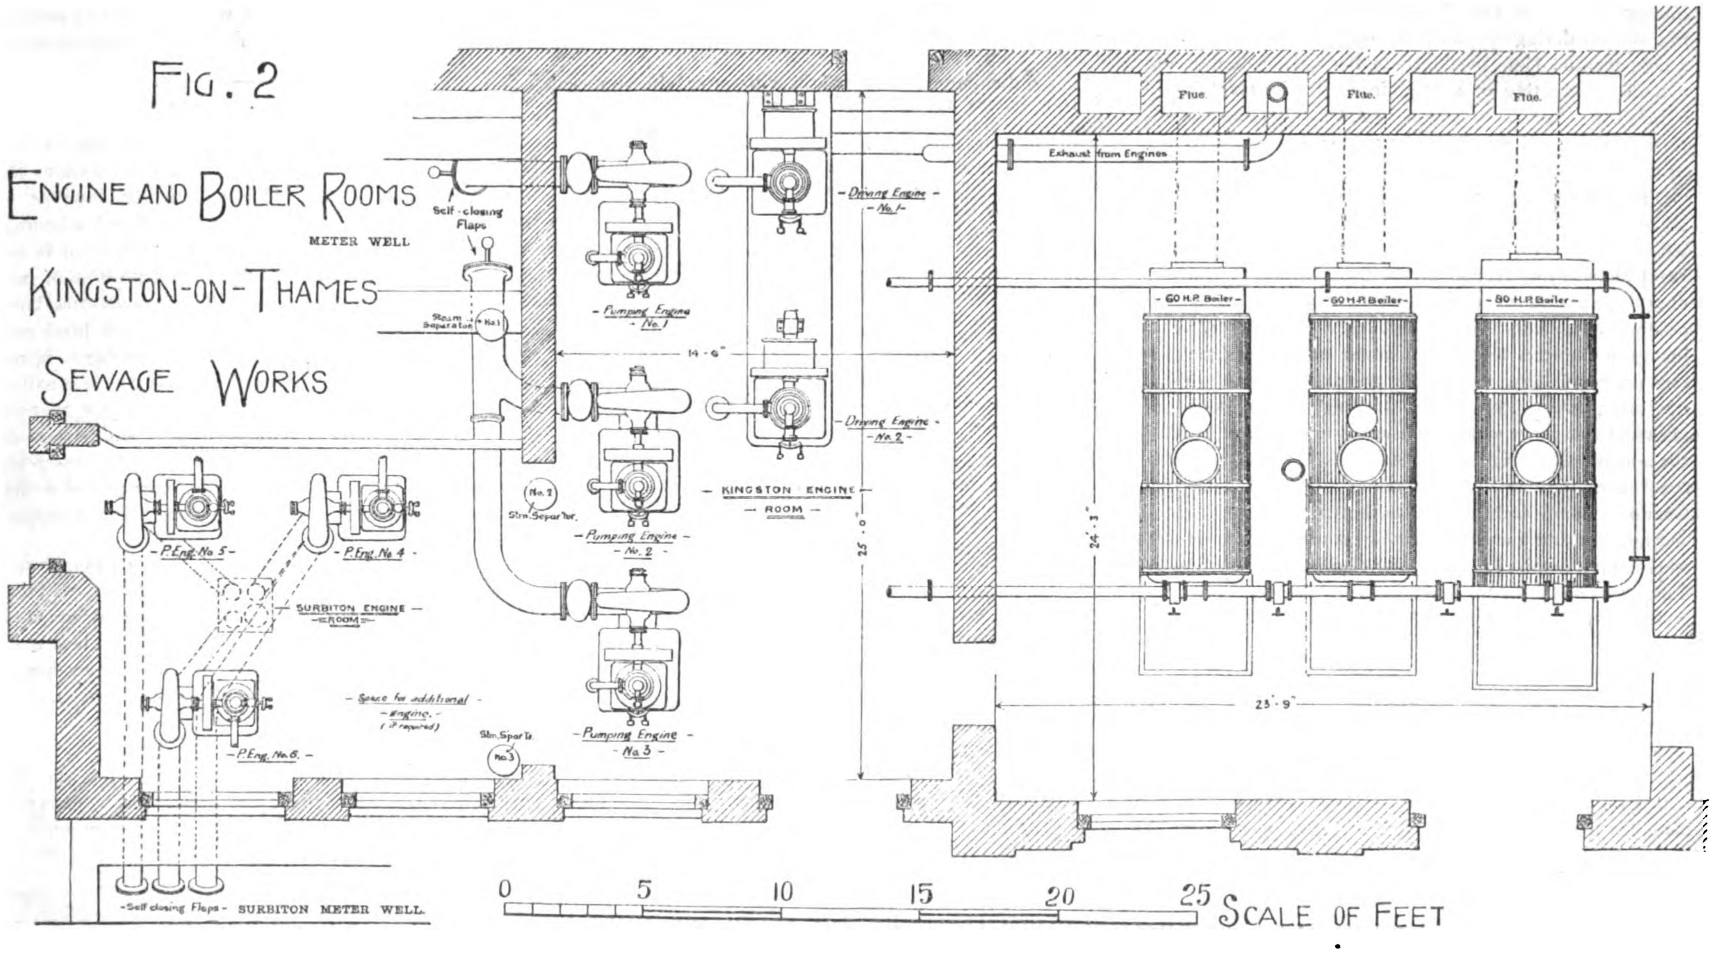

FIG. 2 ENGINE AND BOILER ROOMS KINGSTON-ON-THAMES SEWAGE WORKS

building as one stream into an open channel. Here it receives a solution of alum, dropping into it from a little serrated bridge. This acts as a precipitant, curdling the particles held in suspension. The sewage thus prepared travels onward to the settling tanks. These are eight in number, arranged in two sets of four each with a walk between. The sewage is made to flow along two separate conduits, each flanked by four of the tanks. Each of the eight tanks has a capacity of 150,000 gallons, each being 85 feet in length and 50 feet broad, with an average working depth of 6 feet. The eight tanks are therefore capable of holding 1,200,000 gallons, equal to 30 gallons a head for 40,000 people. Each tank is of twin construction, having a baffle wall running out about three-fourths of its length from its inner end. The tanks are worked in pairs and are interchangeable and auxiliary, flood-gates in the channel courses diverting the sewage into or from each, as desired. Flowing into the first tank as a black and repulsive looking liquid, though without any bad odor, the sewage undergoes precipitation in two stages. It is first passed into the first division of the first pair of tanks in use and runs around the baffle wall until the tank is full. Then, the heavier particles having in great measure settled, the effluent overflows into a head leading to the inner of the double row of channels. This effluent is then comparatively clear and free from smell; it is, however, directed into the second of the tanks, which it also fills to the overflow, when it is run into the outer channel and passes off perfectly bright and clear into the Thames.

In its course to the outlet the channel is "flared" out with an inclined plane, so that the fluid is spread with very little depth over a large surface so that it may be oxygenated. Underground conduits connect the tanks with a double-action Tangye-Holman sludge pump, by which the sludge is periodically pumped from the settling tanks into a sludge well by a Tangye-Holman double-acting pump at the rate of 500 gallons per minute, and from this well it is drawn up into four sludge receivers or accumumulators by exhausting the air from them. They are each 4 feet 6 inches in diameter and 12 feet 6 inches high. When the receivers are full the valves are reversed and air is pumped into them at a pressure of 100 pounds per square inch, which forces the sludge into a set of filter presses, eleven in number, situated on the first floor of the building. The air pumps, which are used alternately for exhausting and forcing, are two in number, and have been constructed by George Scott & Sons, of London. They have cylinders 6 inches in diameter by 6 inches stroke.

The filter presses express from the sludge about 80 per cent. of the contained moisture, the residuum taking the form of hard flat cakes of a black color, free from smell, which are removed by hand. As soon as a sufficient quantity of "press cake" has been stored it is subjected to a further drying process by being passed down through a hopper into an improved form of Borwick's patent drying cylinder, consisting of a large iron cylinder revolving in a furnace. The dried cake is afterwards ground and returned by an endless band elevator with buckets to the upper floor, where it is bagged and sold as native guano.

The meter referred to was designed by Mr. Robinson, and consists of an undershot water-wheel of special design, which is rotated by the sewage as it passes through. The revolutions, being recorded an a dial, indicate the amount of sewage passed in a given time, with an error not exceeding, it is said, 1 per cent. The meter is 5 feet 6 inches in diameter and 5 feet broad, and passes 483 gallons per revolution. The meter can also be made to work the machinery employed for feeding in the purifying chemicals, so as to supply the latter in an exact ratio to the amount of sewage measured. Its use was rendered requisite by the terms of the agreement between the Native Guano Company and the local authorities.

Figures 1 and 2 are, respectively, a general plan of the works and a detailed plan of the engine of boiler-house. The course taken by the sewage is indicated by the arrows in Fig. 1, though it must not be supposed that all the sewage flows at all times in all the directions shown by the arrows in the settling tanks, which merely indicate alternate or alternative routes, as while some of the tanks are in use, others are being cleaned out. The alum is added to the sewage at A.

"A Subscriber," of Philadelphia, is requested to send his name and address before we can undertake to answer his letter.

RECENT CONSTRUCTIONS IN RAILWAY BRIDGES.

In a paper on the above subject, read at the last meeting (August 12) of the Civil Engineers' Club, of Cleveland, O., Mr. James Ritchie pointed out that the largest recent bridge of note is that across the Ohio River at Ceredo, W. Va., known as the Ceredo bridge. It consists of one channel span 518 feet, two side spans 298 feet each, and a series of approach spans, the total weighing upwards of 3,250 tons. A large number of other bridges are in process of construction, including many plate girders, and fixed and draw spans up to 212 feet. In the Southwest considerable iron bridge construction is going on, and in the Northwest there is an increasing number of iron bridges. In the Northeast, also, many bridges are building. The Maine Central road is replacing its wooden bridges with iron ones, while the New York Central is building several bridges of steel.

Particular mention was made of a plate girder span of the New York Central, 115 feet in length and 9 feet deep, in which the web plates are placed with the fibre vertical.

The new swing bridge on the Lake Shore Road, across the Cuyhago River at Cleveland, was described as a double track through bridge 306 feet long with steel eye bars, and the balance of iron. The total weight of the superstructure is 328 tons, and of the turn-table, 133 tons. A table of actual weights of spans from 30 feet to 200 feet was given.

In commenting on specifications of bridges Mr. Ritchie regards those by Mr. George S. Morrison, for the Memphis bridge, as the most complete and systematic, and on account of the minuteness of their details they are not likely to be evaded. Nothing impossible to comply with should be written in specifications, but all reasonable conditions should be rigidly enforced. The use of steel in bridges seems to be increasing, and many roads allow Bessemer steel or open hearth to be used, while the New York Central allows the use of acid open hearth only.

In testing full sized iron eye-bars to destruction Mr. Ritchie has noticed that failure takes place near one head or the other, indicating that the material might have been injured in manufacturing. He, therefore, recommends annealing as is done with steel bars. This might not produce the desired result, but a few experiments in this manner might be of great benefit.

THE EFFICIENCY OF FACTORY CHIMNEYS.

In an article on "The Height of Factory Chimneys," published in The Engineering and Building Record, July 5, 1890, attention was directed to the prevailing tendency to build chimneys for boiler plants of much greater height than is necessary. Bearing further on this subject the following, taken from the *Journal du Gaz et de l'Electricit* and credited to a German source, is of interest:

"An old chimney, 67 feet high, with internal diameter of 19.6 inches to 13.8 inches, and with total passage, from fire to chimney top, of 98 feet, was taken down, and a new chimney, with an intended total draught of 95 feet, and a minimum internal diameter of 25.5 inches was planned out. When the chimney had gone up 39 feet, it was tried. Already there was a great improvement on the old chimney; again at 46 feet, still better, and at 52½ feet the draught was excellent, and there was an economy of from 15 to 20 per cent. in fuel. The chimney was therefore finished off at that height. Herr Huth thinks chimneys are usually made too narrow, and the mischief is aggravated by increasing their height, so fuel escapes unburned. Herr Ramdohr, of Gotha, confirms this, and recommends a uniform internal diameter as being more rational, and as protecting the brickwork from the hot and rapid axial stream. The cross section of the chimney should be from one-fourth to one-eighth the grate area, and the height, not less than 50 feet, should not exceed 100 to 120 feet (the diameter being made to suit), unless the chimney is at a distance, in which case it may be 160 to 200 feet, the diameter being regulated according to the amount of soot which escapes."

GROWTH OF BAMBOOS.

Stories as to the rapidity with which bamboos grow are current all over the East, and the newcomer is often regaled with some rather tall stories in this connection. According to *Indian Engineering*, however, Dr. Trimen records in his Administration Report of the Peradeniya Gardens, Ceylon, for last year, that one of the culms of giant bamboos in the gardens grew last April at the rate of 13½ inches in 24 hours. As this is properly authenticated, the circumstances is notable.

CORROSION FROM SOFT WATERS.

In a paper on the Sheffield, England, water-works, recently read before the British Institution of Mechanical Engineers, Edward M. Eaton, the chief engineer of the works, referred to the extreme energy displayed by the soft Sheffield water in attacking metals exposed to its action. This was shown by specimens of a wrought-iron screw spindle, nuts, bolts and washers. These had been wholly immersed in the water to a considerable depth for a period of more than forty years, and the manner in which the pure metal was eaten away was most remarkable. It has been found also that steel blades, such as razors, scissors, pocket and table knives, and also files suffer complete deterioration to a considerable depth from the surface of the metal, when immersed in the water for several years. This has been proved by the recovery from time to time from the reservoirs of bundles of such steel articles which had doubtless been placed there in connection with trade outrages in times past. The steel was found to have been converted into plumbago, whole bundles of blades being capable of being scraped away with a penknife.

Referring to this, Mr. C. Cochrane pointed out that in the manufacture of cast-iron water pipes the use of graphitic grey iron was not usual, it having been abandoned for the harder white iron. E. P. Martin said that at Dowlais they had had much the same experience with regard to corrosion in the case of a boiler fed with very pure water. They had, however, put a few cart loads of lime into the stream from which the feed water was obtained, and from that time forth the trouble ceased.

Mr. Eaton said that wrought-iron pipes could not be used with the Sheffield water, as they would be eaten through or choked up in three years; but cast iron lasted well, although they were sometimes troubled with "tubercles" of oxide of iron combined with peaty matter, the cause of which was obscure. These formed in spite of a constant stream with a pressure due to a head of 400 feet. Under these tubercles the ordinary coating of scale was found to be intact. Within the last few years they had had much trouble with lead pipes, and the water did seem to act on lead in a remarkable manner, in fact, it seemed at first hungry for any impurity and would take up anything, and if the first thing was lead it would take up that. This, however, was a property common to other waters besides those of Sheffield. In some other places a lime treatment for this defect had been tried. In Sheffield they had met with some encouragement in the use of finely divided chalk. A curious feature about the action of the water on lead was that it was found to be more active at certain seasons of the year. There was no doubt that iron pipes were often affected by the acids in the made ground in which they were buried. Sulphur was the chief cause. Some of the iron which was made soft by remaining in the water became hard again when exposed to the air.

BLACKENED CEILINGS.

It is generally supposed, says *Industries*, that the use of the incandescent electric lamp completely obviates the blackening of ceilings. This is a mistake, however, as incandescent lamps do to some extent cause blackening. It is probable that the blackening from a gas lamp is not due to unconsumed carbon, but to the deposition of particles from a current of hot air. The incandescent lamp causes a current of hot air, which also deposits black particles; but, unless the lamp is near the ceiling it is not easily observed, as the current of air is, of course, smaller. It may be noticed in connection with this subject, that the mica guards and glass bells arranged over gas burners do not themselves blacken, and do not appreciably lessen the blackening of the ceiling. It is therefore probable that the deposit only takes place from hot air to a cold surface.

The Nordenfelt submarine torpedo boat, launched a few years ago, of which so much was expected, is no more. On her way to Cronstadt last year she stranded on the coast of Jutland, was got off and repaired, since when the vessel has been lying in Copenhagen roads awaiting a buyer. At last the torpedo boat has been purchased as old iron and broken up.

English papers contain accounts of a new gun, the propulsive agent in which is carbonic acid gas, compressed to a liquid condition and capable of giving a pressure of 500 pounds per square inch.

THE PROPOSED LONDON TOWER.

FOLLOWING the general illustrations of competitive plans for this structure which have been published in recent issues of THE ENGINEERING AND BUILDING RECORD, we give herewith one of the plans in considerable detail, prepared from the drawings and specifications of the author, so as to present the principal features and solution of a construction problem that is interesting from its exceptional novelty and magnitude.

COMPETITIVE DESIGN AND ESTIMATE FOR A TOWER, 1,400 FEET HIGH, FOR THE TOWER COMPANY, LIMITED, OF LONDON, BY EDWARD S. SHAW, CONSULTING ENGINEER, BOSTON, MASS, 1890.

The tower will present a curved outline, from the principal floor, 360 feet high, to a point near the top. This is attained by making the tubular columns in comparatively short lengths, which are placed as the chords of a curve, and by connecting them at the intersection of the diagonals by junctions which are also chords of, or tangent to, the curve at these points. Besides the floors shown in the illustrations, there is a room about 10 feet in diameter, surrounded by a balcony, at a height of 1,388 feet from the ground, to be used for an electric light lantern. On the top of this room will be a deck or standing room, 10 feet in diameter, protected by a railing at a height of 1,400 from the ground.

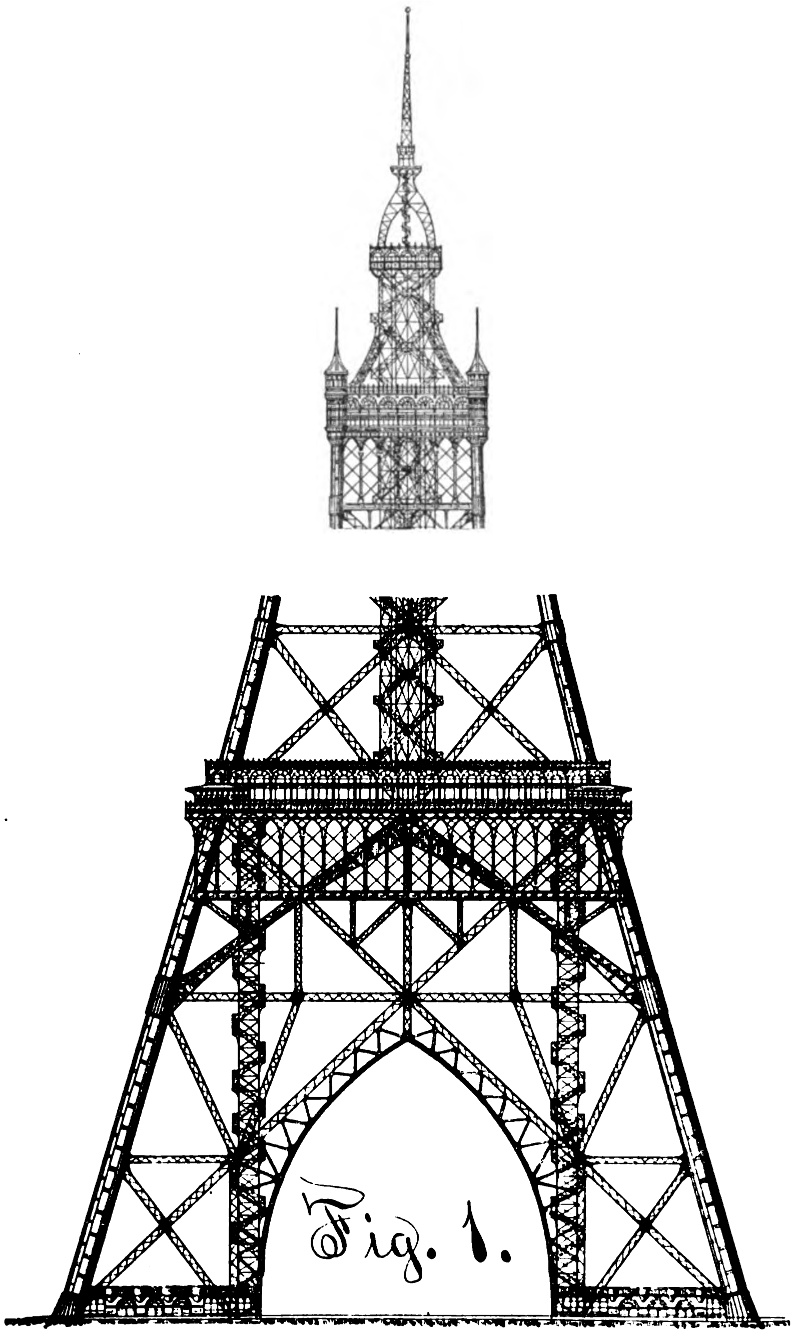

Fig. 1.

TOWER 1400FT. HIGH DESIGNED BY EDWARD S. SHAW.

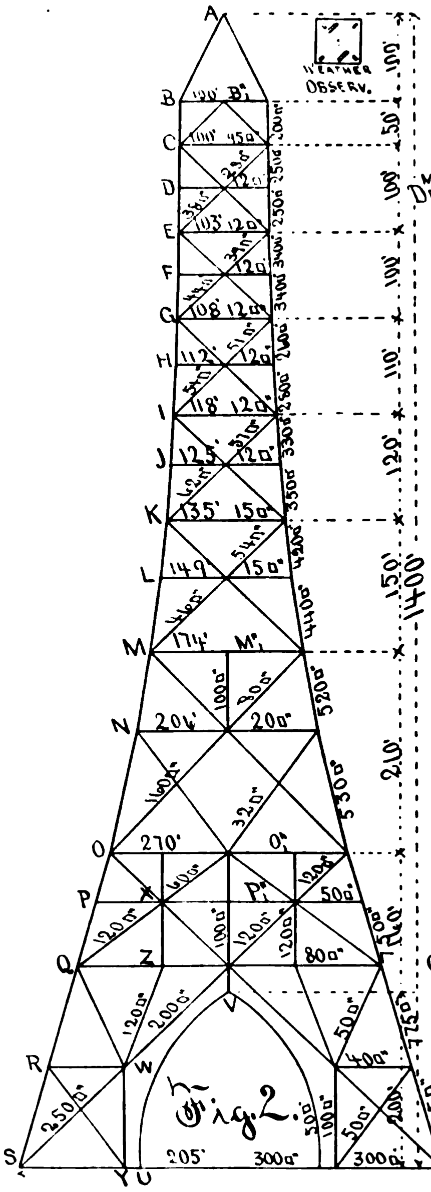

Fig. 2.

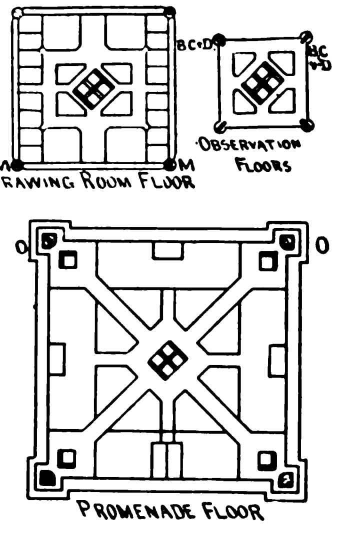

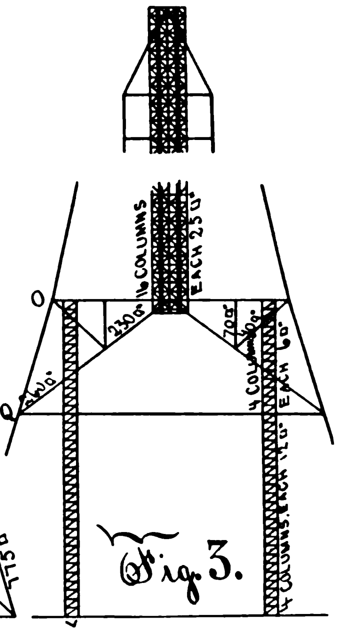

Fig. 3.

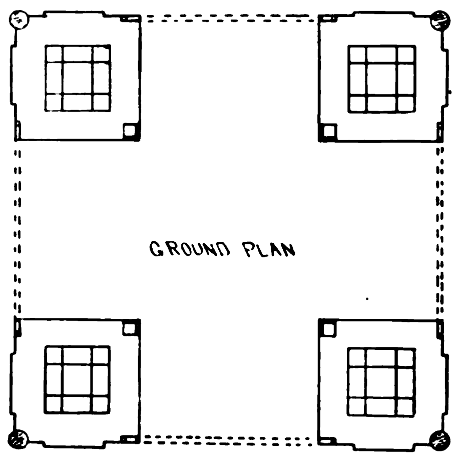


1400FT TOWER
DESIGNED BY
EDWARD S. SHAW
BOSTON MASS.

Access is had to the several floors by means of four shafts, carrying staircases and lifts from the ground to the principal floor (360 feet in height), and from this floor to the top of the tower, by a single shaft, having four wells for lifts and provided with staircases. This latter lift shaft is placed at an angle of 45 degrees with, or diagonally to, the main tower, in plan, and is connected horizontally with the principal tubular columns, by diagonal members passing through it.

FLOORS.

The ground floor consists of four pavilions, each 140 feet square, covering a total area of about 74,000 square feet, and situated adjacent to the four corners of the tower, and contains offices, restaurants, shops, etc.

The first and largest floor above the ground level is termed the promenade floor, from the covered promenade 1,200 feet long and 15 feet wide surrounding it. It covers a net area of about 75,000 square feet, and is situated at a height of 365 feet above the ground. It contains a general public hall, 50x160 feet; kitchens and toilet rooms.

The drawing room floor is at a height of 575 feet above the ground, and contains a net area of about 28,000 square feet. It is proposed to have this floor fitted and furnished in a more elaborate and expensive manner than the other floors, and to charge an extra price for admission. It may contain a general drawing room (for both sexes), restaurant, gentleman's room (smoking), ladies' drawing room, private drawing rooms (may be hired by the hour or day), toilet rooms, etc.

The upper public floors of the tower will be situated at a height of from 1,200 to 1,230 feet from the ground, and will consist of a covered floor 100 feet square inclosing an area of 10,000 square feet; a covered gallery 10 feet wide extending around the four sides of the tower directly above the principal floor; and a flat roof or deck, which may be used by the public in fair weather, and which covers the same area as the floor below. The total available area of these floors and galleries is about 20,000 square feet.

At a height of 1,318 feet from the ground is a floor 50 feet square, inclosed and covered, which may be used as a weather observatory or signal service station, and fitted up with the proper instruments for this purpose. Above this, at a height of 1,388 feet, is a lantern 10 feet in diameter, which may contain a powerful electric light. The roof of this lantern is surrounded by a railing and constitutes the highest standing room upon the tower, 1,400 feet from the base. Above this point extends a tapering latticed column, the upper portion (30 feet) being a circular column of uniform diameter. This staff will serve as a lightning protector and a signal staff upon which flags denoting the condition of the weather may be hung. The principal upper floors are further protected from lightning by four iron poles extending upward from the tops of the four turrets which surmount the principal columns at the corners of the tower.

ELEVATORS AND STAIRCASES.

From the ground floor to the promenade floor are four vertical shafts for elevators, 15 feet square, each shaft being surrounded by a staircase. From the promenade floor to the weather observatory floor, a distance of 950 feet, there is a single shaft situated in the center of the tower and provided with four wells for elevators, each about 13 feet square. All staircases are 3 feet wide, with steps having a rise of about 7½ inches and landings 3 feet square. They will be protected upon both sides by fenees or railings 5 feet high, the lower portion of which are solid girders carrying the steps.

The elevators from the ground to the promenade floor are 13 feet square inside, with two floors, each elevator having a capacity of 60 persons without crowding. The elevators from the promenade floor to the top of the tower are 11 feet square inside, with two floors, each elevator having a capacity of 50 persons. It is proposed that one-half of the elevators shall have a speed of 400 feet per minute, and the other half a speed of 200 feet per minute, as it is unpleasant to many persons to ride in fast elevators. The time occupied by one trip, including loading and unloading is estimated as follows: Ground to promenade floor, fast elevators, 2 minutes; ground to promenade floor, slow elevators, 3 minutes; total capacity per hour to promenade floor, 3,000 persons. By increasing the speed of the slow elevators the capacity can be raised to 3,600 persons per hour. From promenade to observation floors, fast elevators, 3½ minutes; from promenade to observation floors, slow elevators, 6 minutes; total capacity to observation floors, 1,350 persons per hour. This can be increased to 1,500 per hour by running three of the elevators at a speed of 400 feet per minute.

The tower is designed to sustain, first, its own weight; second, a live or moving load, covering all of the floors, of 56 pounds per square foot, this load being increased to 112 pounds per square foot upon members directly supporting portions of the floors liable to be crowded; third, a wind pressure of 56 pounds per square foot, acting upon double the exposed side area of the tower, with a deduction of one-half for tubular members, and plane surfaces inclined at an angle of 45 degrees to the direction of the wind. The total wind pressure upon the tower is estimated at 3,000 tons. With the above loads the stresses per square inch employed are as follows: Upon steel in compression 5 to 7.5 tons per square inch; upon steel in tension, 6 to 7.5 tons per square inch; upon iron in compression, 3 to 5 tons per square inch; upon iron in tension, 4 to 6 tons per square inch; according to position and duty, the stress being reduced, as the ratio of live to dead load and minimum to maximum stress increases.

The details of construction of the principal parts of the tower are in many respects similar to the details of the Forth bridge. The principal columns at the four corners of the tower are plate iron tubes 16 feet in diameter and ¾-inch thick at the base, and 8 feet in diameter and ⅜-inch thick at the top. They are built up of 16 plates in the circumference at the base, 12 plates at the middle portion and 8 plates at the top, with internal ribs of I-shaped section and stiffening rings. The diagonal and horizontal members are generally four channel shaped sections, with triangular web bracing of angle section. They are connected with the tubes and at their junctions by plates. The junction members of the tubes are flattened upon the inside surfaces to facilitate the attachment of diagonal members, and provided with four internal webs extending across from side to side. The floors are supported by steel trusses and girders, with steel I-beams for floor joists, the space between the beams being filled with flat arches of hollow terra cotta, and covered with asphalt or tiles bedded in cement. The elevators and staircase shafts are constructed of vertical columns of channel or Z section connected by horizontal struts and diagonal ties. Steel is used for all the heavier members and iron for the lighter ones, the rule being to use iron where the section required for steel is less than ⅜-inch.

FOUNDATIONS.

It is proposed to make the foundations principally of Portland cement concrete. Those under the principal columns are 25 feet in diameter at the top, 40 feet deep, and 60 feet in diameter at the base, in the form of truncated cones. The upper courses of these foundations are of cut granite. The estimated vertical pressure upon the top of each of these foundations is 6,400 tons; the weight of the foundation is 3,500 tons, and the pressure per square foot upon the ground at the base of the foundations 3.5 tons. The horizontal thrust of the columns due to the vertical load is taken up by horizontal ties just under the surface of the ground, leaving a horizontal thrust of not exceeding 900 tons upon each foundation. Anchors will extend down to a point near the base of the foundation, and be connected there to heavy girders embedded in the concrete.

The cost of rolled bars, plates and shapes is estimated at £9 to £10 per ton for iron, and £10 to £11 for steel manufacture; erection and painting of the same at £13 to £14 and £14 to £15, respectively.

The summary of estimates gives—

(A.) Constructional steel and iron, 17,790 tons, £437,916; balustrade railings, cost, £1,080; ground floor, walls, partitions, floor and roofs, cost, £30,570; promenade floor, walls, partitions, floor and roofs, cost, £31,758; drawing-room floor, walls, partitions, floor and roofs, cost, £15,653; observation floors, walls, partitions, floor and roofs, cost, £8,195; weather observatory floor, floor and roofs, cost, £1,013.

(B.) Foundations, £28,400; excavation, £3,750; lifts, £9,600; plant for operating lifts, £8,000. Total cost of tower, £575,933.

11,987 tons of steel, at £302,671, and 790 tons of iron, at 18,491 £ for the tubes, diagonals, trusses arches and buttresses are included in item A. In item B the foundations of the principal columns are estimated at 10,800 cubic yards, at £2 per cubic yard.

Excavation throughout is estimated at £3 per cubic yard, and the elevator plant is of 100 h. p., with electric generator and motor for the upper elevator.

Figure 1 is a general elevation of the tower, Fig. 2 a diagram of principal sections and dimensions, and Fig. 3 shows the arrangement of elevator shafts.

ANNUAL REPORTS.

REPORT ON THE PROJECTED WORKS OF THE TULARE IRRIGATION DISTRICT, TULARE COUNTY, CAL.; by the Board of Directors and the Engineers.

On September 21, 1889, the Board of Directors of the Tulare Irrigation District was organized, and undertook to ascertain the most available and acceptable routes for irrigating canals and works, and to estimate and determine the amount of money necessary to be raised for construction. For this purpose John S. Urton, C. E., of Hanford, was engaged to make the necessary surveys, investigations and estimates, and his report forms part of the pamphlet. The result of his investigations was the conclusion that further and more detailed surveys of the proposed irrigation works were necessary. The services of P. J. Flynn, C. E., of Los Angeles, were therefore secured, and to his report the greater part of the pamphlet is given up. The line recommended by Mr Flynn has been adopted, and it is intended to call for bonds to the amount of $500,000 for the work of construction.

Mr. Flynn estimates that $353,476 will suffice for building the line, but the Board of Directors believe it advisable to have an ample surplus as a contingency fund for purchasing water rights, etc., if occasion shall arise.

REPORT ON THE OPERATIONS OF THE SANITARY DEPARTMENT OF THE CITY OF GLASGOW; for the year ending December 31, 1889; by Peter Fyfe, Sanitary Inspector.

THE report shows that during 1889, 13,128 persons died in Glasgow, making a death rate of 25 per 1,000 of the population. This as compared with the year 1874, when the death rate was 32 per 1,000, shows a marked improvement in the sanitary condition of the city. A review is given of the different city districts, and their evil features are pointed out. An appendix contains a report on the stabling of cows within the city. Comprehensive tables also are given, furnishing details of the epidemic and nuisance inspectors' work, and of the sanitary inspector's work.

A DOVER, N. H., despatch states that suit was entered against the city on August 15, by John H. Leavitt, who contracted to build, and built, the upper well of the Dover water-works. In constructing the well it caved in badly, and cost him a good deal more than he expected. He claims pay for the extra work that the caving in caused him, to the amount of $3,390.12, with interest, making a total of $3,713.05. The city denies that it is under any obligation to pay for extra work, as Leavitt took the job for a fixed sum, and took his own risks.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

THOSE DANGEROUS TRUSSES AGAIN.

BROOKLYN, N. Y., August 19, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: I am glad to see that my letter about the dangerous trusses in Hermann's Theatre, published in your last issue, has attracted considerable attention to the matter, and, according to the daily papers, has led to some changes being made in the trusses and in the supports of the iron beams. I shall watch with some interest to see if the proposed changes are really improvements. It is reported in the *Standard-Union* that the iron pillars "are to be reinforced with substantial *wooden* posts;" rather an unusual construction certainly in a new building. Why not put in proper iron pillars to begin with, especially as only one of them has so far been put in place? As white or yellow pine compresses about ten times as much as cast iron under a given load it is very obvious that it will be next to impossible to get supports of such dissimilar material to work together to any sort of advantage. It will be like the "new cloth in the old garment," only more so.

In the Brooklyn *Eagle* it is said to be the architect's "intention to strengthen the trusses by means of two rows of braces, and although this is not by any means what the plans call for," it is said that the commissioner would be satisfied with it. Apparently this can only mean that diagonal braces are somehow to be inserted between the vertical struts shown in the sketch accompanying my first letter, and it is obvious that though this may be so done as to give a somewhat better support to the center of the timbers that form the top chord it adds nothing whatever to the effective depth of the truss. Right here I may say that though it is claimed that the truss rod is 1½ inches in diameter instead of 1¼ inches as I supposed it to be, yet the correctness of my calculation is in no wise affected thereby, for, willing to be liberal where the discrepancies were so great, I assumed the rod to have its full area at all points, but as a matter of fact its section is reduced by having a screw thread cut upon it for the turn-buckle in the middle and the nuts at the end, so that even if it was 1½ inches in diameter to begin with it has, at the critical points, only the effective area of a 1¼-inch rod. It is not even as good as if its effective area had been reduced in the same proportion for its whole length, and for the same reason that it is safer to cross a brook on an inch board than on a two inch plank that has been cut half through in the middle, for in the latter case the tendency to break has been concentrated at one point and it will not spring or "give" as much before breaking.

Since my first letter was written I notice that a partition has been put up in the first floor, distant perhaps 6 feet from the side wall, which may in a measure reduce the load on one of the trusses, although the shrinkage and compression of the plates and beams render that very uncertain; but I was astonished to see also that a partition had been put up on the second floor right over the most heavily loaded truss. The beams of the floor above break joint on this partition which thus transmits to the truss below full half the weight of another floor, and taking the dimensions given in my last letter, and assuming the weight at only 100 pounds per square foot, this is 30 × 16 × 100 = 48,000 pounds, an additional load of nearly five times what I showed last week would be safe for the truss to carry even if properly braced. Altogether, even supposing the partition below to take its full share of the load, this unhappy truss is, to all appearance, liable to have to sustain seven or eight times as much as would be safe to put upon it, or about twice its breaking load. Comment is unnecessary.

If there is anybody in the Department of Buildings who is capable of figuring such matters it is charitable to assume that he is enjoying his vacation, and it is to be hoped that work on the building, which seems to have been suspended since your publication of my letter, will not be resumed until he has returned and given the matter his most careful consideration.

I notice that Mr. Allen, the architect, is quoted as saying that "'Civil Engineer' has labored under a mistake in his figures, his calculations are wrong, and he don't know what he is talking about," but as not the slightest evidence is offered in support of this sweeping statement it is perhaps safe to assume it to be merely the expression of a very natural irritation in which "the wish was father to the thought." CIVIL ENGINEER.

[As the accuracy of some of the statements and calculations regarding Hermann's Theatre contained in the letter from "Civil Engineer," which was published in our last issue, appeared from the daily papers to have been questioned by the architect of the building and others, a representative of THE ENGINEERING AND BUILDING RECORD visited the theatre, where he found work suspended pending the settlement of the matters in dispute. On examining the plans it appeared that the description of the trusses was substantially correct, differing, however, in the following particulars: The truss rod was 1½ inches instead of 1¼ inches, although as the ends were not upset its effective area was only 1¼ inches. The top chords were only 4x12 inches instead of 4x14 inches as estimated, while the total length of the truss was 33 feet 2 inches instead of 30 feet as estimated, the center struts being 6 feet 6 inches apart.

The effect of these differences on the timbers of the top chord, considered with reference to their transverse strength for the middle portion of their length, is to make that strength about 26 per cent. less than estimated, and to make the bending moment of the load, supposed to be the same per square foot, about 15 per cent. greater than estimated, altogether making the disproportion between load and strength over 50 per cent. greater than estimated.

If, however, the truss were so braced as to properly support the upper chord its strength would then be limited by that of the lower chord, provided the wooden struts did not split or crush. In this case, as the truss is about 10 per cent. longer than was supposed, the bending moment of the same load per square foot would be increased about 20 per cent., which, with the slight reduction in the effective depth due to the lessened depth of the top chord, would make the disproportion between load and strength about 25 per cent. greater than estimated by our correspondent.

These calculations are based on the state of things noted in his first letter; since then, however, the partitions described in his second letter have been added: the apparent effect of the upper one would be to more than double the load on one of the trusses. The Commissioner of Buildings stated that floor loads of 120 pounds per square foot had been allowed for. The floor area supported by one of the trusses, making all allowance for the relief afforded by one of the partitions below, and adding the area of the third floor if supported by the upper partition, would be 864 square feet. This would give a distributed load of 864 × 120 = 103,680 pounds, and give a stress on the truss rod of 160,000 pounds. Taking the ultimate strength of the rod at 50,000 pounds per square inch, which is good iron, the rod would break at 50,000 × 1.23 = 61,500 pounds. The safe load would be about 12 pounds per square foot, or about what the bare floors would weigh.

From the above figures it would appear that the danger to be apprehended from the use of these trusses is considerably greater than "Civil Engineer" had supposed when he wrote his first letter, and the facts, as ascertained by our representative, fully justify the confidence which we placed in our correspondent's statements and calculations. None of them has been successfully questioned except the size of tie rod which, as he said, he was obliged to estimate, and that difference was fully covered by the ample allowance he had made in his calculations. Of his other statements, though strongly condemned in general terms by interested parties, not one has even been specifically questioned, much less disproved.

The rolled beams to which our correspondent called attention are 20-inch steel weighing 64 pounds to the foot, and are 30 feet long. Their safe distributed load would be 81,500 pounds. They were to be supported at each end by cast-iron pillars 6 inches in diameter, 1 inch thick and 16 feet 6 inches long. The breaking strength of such pillars is about 170 tons each if bearings are perfectly true; if such is not the case the safe load will not exceed $\frac{1}{16}$ of that or about 11 tons, little over half of what the beams would safely carry. The upper ends of these pillars are rough, but the lower ends are turned. The one in place rests directly on a piece of rough blue stone about 16x20 inches, its center being about 4 inches from the end of the stone, which, in its turn, rests on a 16-inch wall 8 or 10 feet high, in which there do not appear to be any bond stones. These pillars are to be reinforced by yellow pine posts.

One of these posts has been put in place. It is 8x10 inches. At the bottom it rests on 14 inches of plank blocking laid on the side, giving an indefinite amount of compressibility, and has not even been squared off to get a fair bearing on that, as the end of the finger could be run under it for some distance. At the top it is cut away for more than half its width to accommodate the capital of the cast-iron pillar, which is some 14 inches square.

On this unfinished capital, which, from the draught of the pattern is quite crowning, the steel beams are shimmed up with wooden wedges, while under one side of the lower end of the iron pillar the end of a rule can be readily inserted, so poor is its bearing on the stone.

The plans for the additional bracing of the trusses had not been received up to the time of going to press, but the Commissioner stated that they merely contemplated putting diagonal bracing between the struts without increasing the depth of the trusses. In view of the fact that work on the building, which has been stopped by the owner since last Saturday, has not yet been resumed, the Commissioner thinks that the trusses will probably be replaced by some more satisfactory construction, especially as the owner did not appear to be favorably impressed by their appearance when his attention was called to them.

The architect of the building is J. D. Allen, of Philadelphia, and the general contractors are R. C. Ballinger & Co., of the same place.]

BUILDING INSPECTION IN BROOKLYN, N. Y.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

BROOKLYN, August 11, 1890.

SIR: The subject of building inspection is a serious one, and I am one of those who think the liberty of our institutions should be allowed to govern all things. If public sentiment and private interests could so shape our policy that only skillful architects and engineers would be employed, we should be safe in trusting all, as we must trust much in any event to them.

Building inspectors are not generally skilled men, and rarely ever architects or engineers. Somewhere should rest the power to insist that only good men should plan and build structures in and over which human beings must live and move.

The criticism of your correspondent, "Civil Engineer," recalls several instances of faulty construction in buildings in this city. Our administration of such matters is different from that in New York City, and probably inferior thereto. Our interests are just as essential and very similar to those in the greater city. For three purposes at least—health, police and public works—the two cities should be served by the same rules, if not by the same officials.

I noticed the other day, in the repairs being made at a large brick building, necessitating the introduction of a heavy iron floor beam to carry wooden beams, till then resting on a partition wall which was being removed, that the new beam was made to rest on the outer edge of a cast-iron column cap. The end of this beam did not extend over the body of the column at all, and had only about four square inches bearing on the outer edge of the column cap. It would have been easy to attach supporting angles of sufficient strength to transmit the shear of the new beam to a cross girder already resting squarely on the column. Instead of this the beam was left to exert a bending stress on a 6-inch cast-iron column, or to shear off the ornamental cap, or both.

In the demolition of the old Brooklyn Theater one of the outside columns, carrying a heavy canopy, broke in handling and exhibited a section 8-inches in external diameter, the metal on one side being 1⅜ inches thick, while that on the other side was about $\frac{3}{16}$ inch thick. The special Providence that watches over drunkards and children had prevented serious disaster during the life of this eccentric old column.

An excavation something like 100 feet square is being made in a thickly settled portion of the city and will be carried about 30 feet deep; for economical reasons no sheeting or bracing was provided for. The slopes in clean sand which were left and intended to stand at a slope of about 60 degrees have caved in so as to endanger neighboring fences and buildings and seriously inconvenience the workmen in starting the foundation walls. An ordinary heavy rain might easily bring the slopes down to 45 degrees and endanger buildings and streets. A casual glance at the present condition of the work will show that the inconvenience to construction will overbalance the saving in omitting sheeting. Should serious slides occur, heavy damage will result.

No doubt many have observed the peculiarly light and airy construction in the repairs of the building corner De Kalb Avenue and Fulton Street, where semicircular arches of iron beams are made to support the front wall of brick of the old upper story; the thrust is intended to be taken up by tie rods and the total weight ultimately rests on cast-iron columns. The construction contrasts strikingly with the strong modern buildings designed by our best architects and is certainly very close on the margin of safety.

The problem is left almost entirely to the owner, which on my theory is correct, if he can only be induced to give the design and inspection of his work and the consequent cost to conscientious architects of acknowledged ability.

BROOKLYN.

[Our Brooklyn correspondent, who is in position to speak with authority, outlines a condition of things which is well known to exist in many places, but which unfortunately too often requires disastrous practical illustration before receiving proper attention. The instances, above cited, of dangerous building practices in Brooklyn, are probably only a few among the large number which have hitherto escaped detection, and we would commend them to the attention of the Brooklyn Building Department as samples of what might be looked for and guarded against by any system of inspection worthy of the name.]

STEEL FOR WATER AND OTHER PIPES.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: The article in your issue of August 2 seems to have been prepared in some misconception of the nature of the question which is now under discussion in engineering circles. So far as I am aware, there is no discussion as to whether cast iron, steel or wrought iron is the best material for pipe manufacture. In the American Water-Works Association the debate took a practical turn, and hinged on the question—understood by the speakers if not clearly formulated in words—whether the superior advantages of steel as a material was not offset by the passive resistance to destructive oxidation in the ground of the heavy and clumsy cast-iron pipes hitherto used. In the New England Water-Works Association, as I learn from a study of their transactions for several years, the discussion has assumed much the same character—cement pipe being contrasted with cast iron, not because it was open to debate whether iron or cement is the better pipe material, but simply which rendered the better service during a long term of years.

I venture the prediction that the days of the cast-iron pipe are nearing an end. They represent too much dead weight for too little strength. Wise engineers long ago reached the conclusion that the most costly and least satisfactory way of protecting iron against oxidation is with mere bulk of its own substance; and those most concerned in the future of the cast-iron pipe, for business reasons realize most keenly the fact that it is destined soon to take its place among the materials forced into disuse by the progress of the arts. Mr. Hamilton Smith, Jr., who stands very high in the profession of hydraulic engineering, in a paper contributed to the British Iron and Steel Institute, and published in Volume I. of their Transactions for 1886, furnished data as to the life and strength of light wrought iron and steel pipes for water conveyance, which left little room for further discussion. He concludes as follows:

"The query presents itself: Why should not wrought iron, or still better, steel, be used for conduit pipes in preference to cast iron? If it answers the desired purpose in California, why should it not do so in other parts of the world? To one like myself, who has for years been accustomed to the California practice, it seems as irrational to build a pipe carrying water under considerable pressure of cast iron, as it would be to build a suspension bridge with the supporting chains made of cast iron.

"Experience in the United States has shown that the practicable limit of size for cast-iron mains is a diameter of about 4 feet, even when the pressure is less than 100 feet. It is evident that a pipe of wrought iron or mild steel can be safely made of almost any desired size, and this may be of much advantage if it be desired to conduct a large supply of water through pipes for city or other use. For instance, with an inclination of 3 feet per mile a single pipe 8¼ feet in diameter will carry 280 cubic feet per second, while seven pipes, each 4 feet in diameter, would be required to transport the same quantity of water with the same inclination. The cost of the large pipe, made of steel or wrought iron, would be considerably less than one-half the cost of the seven small pipes made of cast iron.

"The ideal conduit for high pressures is a welded steel tube; such tubes could probably be subjected to a tensile strain of 25,000 pounds with perfect safety, and would be much preferable to riveted pipe, not only on account of superior strength, but also by reason of almost perfect interior smoothness. * * * The adaptation of a superior and cheap metal, such as mild steel, for conduits will permit the construction of hydraulic works in many parts of the world which now appear to be impracticable, owing to the cost of many of the methods still in use for the transportation of water."

The problem of the protection of steel tubes in the ground is no longer one which causes the engineer any anxiety. A steel tube $\frac{1}{8}$-inch thick, properly coated with asphalt applied in the right way, will, under normal conditions, have a longer useful life in the ground than a cast-iron pipe ¼-inch thick. Meanwhile it will be, what cast iron is not, impervious. The experience in the streets of New York with cast-iron gas and water pipes shows how long they will outlive their usefulness as conduits. The pipe of the present and future is the welded steel tube; and the fact that, the demand for these has always been greater than the available supply would seem to dispose satisfactorily of the idea that they are regarded with a prejudice which must be overcome before they can be generally introduced.

Respectfully,
JAMES C. BAYLES.

THE Columbian Government has passed to the Senate the petition of Lieutenant Wyse, the Panama Canal Company Commissioner, who recently arrived from Paris. Lieutenant Wyse asks for six years' prolongation of the canal company's concession without recompense, and that the Government concede to the company 10,000 hectares of land for the lake which will be formed by the Chagres River, the Government receiving 12,000,000 francs, which sum the company will pay in installments.

SOUTH BALTIMORE was temporarily deprived of water on the 15th inst. owing to a break in a water main.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

HOT-WATER RADIATORS ON A LEVEL WITH THE BOILER.

WILLIAM J. BALDWIN, New York, writes: In your issue of August 9, page 153, "Architect" asks, "Can a hot-water heater be set up as well on a level with the ground floor—that is, in the first story of a house as in the basement or cellar? Can it work to as good advantage in heating the first and second stories? In this town there are no cellars."

In reply, you say in your issue of July 12, 1890: "We show an arrangement of securing circulation through hot-water radiators placed below the level of the boiler. The flow pipe from the boiler is first carried up some distance, in this case to the top of the first story, and is then brought down to supply the radiators.

"The plan has given entire satisfaction. * * * The working conditions of such radiators correspond very nearly with those on 'Architect's' first floor, the boiler and radiators there being on the same level. If our correspondent, therefore, will apply the principle illustrated in our former issue he will have no trouble in getting proper circulation in his first floor radiators."

You evidently do not intend to convey the idea that the plan will give as good results as a *circulation above the boiler*. Still this is the construction many of your readers will be apt to apply to it; hence my letter to you on the subject.

When you tell your correspondent to apply the principles shown in your issue of July 12, and tell him he will have no trouble in getting proper circulation, of course you mean that he will get as good circulation as can be expected under such conditions, always assuming, of course, that his pipes are properly run and sufficiently large. Circulation below the boiler is seldom satisfactory. It is always sluggish and requires very much more heating surface to accomplish a given result than would be required for similar conditions when the boiler can be below the heaters. My advice to "Architect" is *not to do it* if there is any other way out of the difficulty.

Would it not be better to put coils near the ceilings?

[From the nature of "Architect's" inquiry, we took it for granted that he contemplated a job in which the lowest radiators had to be used either on a level with the boiler or not at all. In our reply we, therefore, attempted to show how the problem could be solved under such unfavorable conditions. As Mr. Baldwin points out, they are to be avoided if in any way possible.]

WHEN IS IT ECONOMICAL TO USE EXHAUST STEAM FOR HEATING?

"M. E.," of Jersey City, N. J., writes: "The inquiry in a recent number of your paper as to the economy of using exhaust steam for heating, and your reply to it, suggest a few thoughts on the subject in general.

"Where a manufacturing establishment is using steam for heating as well as for power, or where there are two establishments adjoining, one of which is using steam for power and the other for heating, and the amount of steam required by each is nearly the same, a plant can be erected to generate the steam for use in the two places at a small advance on the cost of a separate plant for each. The reason for this is, that while it is necessary to add about 1,147 heat units to every pound of water of a temperature of 32° Fahr. in order to change it into steam at atmospheric pressure, it requires the addition of only 33 heat units to give us the same weight of steam at a pressure of 75 pounds above the atmosphere. With this work can be performed in the engine, and then the steam can be delivered for heating at a reduced pressure, with but slight loss as compared with the gain resulting from its double use.

"In practice a good automatic cut-off non-condensing engine requires about 30 pounds of steam, of 60 pounds pressure, per hour for each horse-power. Of this about 22 pounds will be delivered as exhaust steam in the neighborhood of atmospheric pressure, and is available for heating purposes; or 71½ per cent. of the heat imparted to the steam in the boiler is actually available for heating after having passed through the engine. The difference between this available heat and the theoretically available quantity is lost in the engine by cylinder condensation, etc. In this manner it would be possible to obtain power and afterwards deliver the exhaust steam for heating. The proportionate cost of the coal would be about $\frac{3}{10}$ for the power and $\frac{7}{10}$ for the heating.

"In other words, if an establishment had been paying $5,000 a year for the coal used in generating its steam for power, and it could subsequently deliver the exhaust steam for heating purposes to some one else, the quantity so delivered would have cost the one using it $3,500 a year for coal if generated by himself, leaving the cost of coal to the one using the steam for power $1,500 instead of $5,000 as before. This can be stated also in another way. If a party is paying $3,500 per year for coal for steam for heating purposes the addition of $1,500 worth of coal will add sufficient heat to enable this steam to be first used to generate power, and then the same quantity of heat can be delivered for heating as before.

"Recently I was called upon by a large candle factory to determine what charge should be made for steam and power which was furnished to a lard refinery next door, where they were using about 4,150 pounds of live steam per hour for general purposes, besides from 15 to 20 horse-power requiring about 64 pounds of steam per hour each, or altogether about 100 cubic feet of water per hour in the shape of steam. To generate this steam from water at a temperature of 122° Fahr. required about three tons of coal per day, or one pound of coal to 7¾ pounds of water changed into steam of 60 pounds pressure. The exhaust steam from the engine was used in the candle factory to heat the feed-water before entering the boilers, and also for heating a portion of the establishment, with such favorable results that it was estimated that an actual saving was effected in coal consumed of 80 tons per year for heating the feed-water, and 30 tons for the heating done during one winter, being about 13 tons saved per month in winter time by the exhaust steam generated by the consumption of 17 tons of coal per month. In this instance no back pressure in the engine was produced."

HOT-WATER HEATING IN PUBLIC BUILDINGS.

"**ARCHITECT**," Hamilton, Ont., asks; "Can you give me the names of some public buildings heated by hot water and where can any information regarding same be obtained?"

[A great number of the United States Treasury buildings in various parts of the country are heated by hot water, probably the latest example being the new Court House at Boston which is now being fitted up. The hot-water heating plant of the State, War and Navy Department Building at Washington, D. C., was described and illustrated in THE ENGINEERING AND BUILDING RECORD of January 22, 1887, and practically the same matter is given in William J. Baldwin's book on "Hot-Water Heating and Fitting." Mr. Baldwin, in this book, describes also the hot-water system at the Westchester, N. Y., Almshouse. Reference to these articles will give our correspondent some of the desired information.]

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department*. Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

SILVER EXTRACTION FROM SULPHURIC ACID SOLUTIONS.

AN English correspondent asks: "Can you give me any information concerning the extraction of silver from a sulphuric acid solution? Can you refer us to any American manufacturers of machinery for accomplishing this by electric methods?"

[Sulphuric acid solutions of silver are generally obtained in treating alloys of gold and silver in which the latter metal always predominates. The gold is separated from the granulated alloy by boiling in concentrated sulphuric acid, which converts the silver into sulphate of silver in the form of a pasty mass. This is dissolved in boiling water and the finely divided gold is left as a black powder, which, when accumulated in sufficient quantity, is well washed and dried. The sulphate of silver solution is drawn off into leaden troughs, where it is left in contact with copper shavings.

The copper enters into solution, forming sulphate of copper, or blue vitriol, as it is commonly called, and the silver is separated, in a finely-divided state, as a gray powder. This is allowed to settle, the solution of copper sulphate is run off into another cistern, and the silver is washed with fresh water, drained and compressed by hydraulic pressure in cast-iron boxes, making cakes of about 60 pounds each. These are dried, melted in plumbago crucibles, and cast into ingots.

The sulphate of copper is crystallized out, after concentration by boiling, and is disposed of for various purposes. When there is no market for the copper sulphate, the solution is decomposed by scrap iron to recover the metallic copper.

We know of no electric method of treating the silver sulphate solution and have been unable, on inquiry, to obtain the names of any makers of electric machinery for the purpose.]

HOW MANY LEAKS ARE ALLOWED IN AMERICAN WATER MAINS?

G. H. **BENZENBERG**, City Engineer of Milwaukee, Wis., writes: "Regarding Mr. W. Perry's inquiry in your issue of August 9, I would say that I do not think any water-works engineer or superintendent will allow any leak to exist knowingly in any length of lines of water main, and I cannot conceive how any one would permit them to exist to a given number per mile or upon any ratio. A leak in a joint under pressure, however small, is too dangerous to permit its continued existence when discovered. It occurs to me that the article referred to may have had reference to leaks that do and will exist on fixtures and along a line of water main, but whose locations are unknown to the authorities, yet the existence of which must be acknowledged and possibly considered in questions touching the consumption or waste of water, etc., and was not meant to convey the idea that American engineers allow their vigilance to slumber to the extent of seven established leaks per mile. That number may have been the result of examinations of long lines of main made for the purpose of locating leakage where the consumption indicated that a leakage must be taking place."

W. L. **CAMERON**, Superintendent of the Artesian Water Company, Memphis, Tenn., writes: "I should say that 'seven leaks' (on an average) per mile of water pipe put down would show a very poor job of pipe laying. I assume that is the question Mr. Perry wants answered. We have 70 miles of pipe, and have put in some 30 miles during the past few years, and I think it is safe to say we have not averaged two leaks to the mile. The fact is that all pipe should be carefully tested before being put in the ground, and their joints carefully yarned, run and calked. We have put in miles of pipe that has never so far developed a single leak."

EDWIN DARLING, Superintendent of the Pawtucket, R. I., Water-Works, writing on the same subject, says: "I do not allow any leaks per mile. We expect perfect work, and a guarantee for one year. I have had laid under my superintendence 70 miles of pipe within the last ten years and have never had 15 leaks on the whole line. If you have a contractor that means to do good work you will have no trouble; if not you can expect more than seven leaks to the mile."

L. H. **GARDNER**, Superintendent of the New Orleans, La., Water-Works, writes: "I have laid a great deal of pipe and claim some experience, but have never heard of such a thing as wilfully providing or allowing leaks in such work. I doubt if your correspondent is serious in his question."

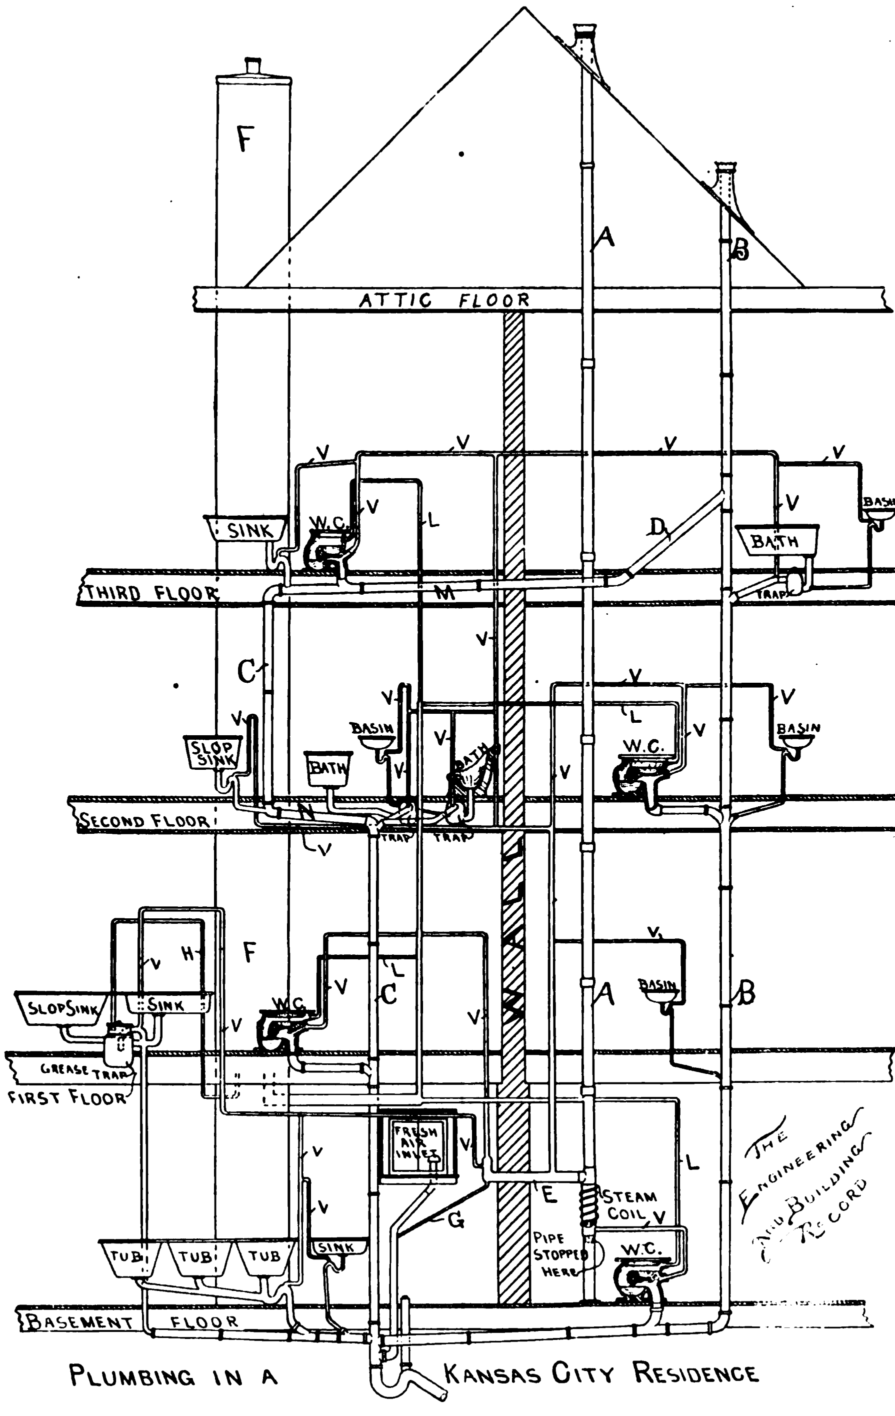
ACCORDING to a Western paper the little city of Lebanon, north of East St. Louis, has taken the initial steps toward the establishment of water-works. A distributing tank or reservoir is to be erected on the public square and water will be pumped into it by the engines of the Lebanon factories.

DOMESTIC
PLUMBING HEATING LIGHTING & VENTILATION
ENGINEERING

PLUMBING IN A KANSAS CITY RESIDENCE.

We print herewith a letter from an old plumbing friend and an illustration prepared from his tracing.

We believe such letters are of especial interest, and that they show and develop interest in the proper arrangement of work and that they will elicit practical discussions and replies, both from the masters in the craft and members who may see points to make and questions to ask.



Plumbing in a Kansas City Residence

The arrangement and laying out of a job, and the efficiency and economy of the system, as a whole, are of great importance, and in these points the young plumber especially has most difficulty. The details of the work, making the joints, fitting the pipes, setting fixtures, etc., are important, but each is separate in itself and only requires skill of hand. It may be tested and criticized by any person of fair mechanical training; a workman may make it perfectly and yet be incompetent to lay out the simplest system. The latter requires ability to apply and follow out principles, the consideration of ordinary and extraordinary conditions, and the best or most available methods at hand.

These qualities are acquired by study, observation and experience; nowadays all plumbers can easily acquaint themselves with the scientific principles involved in their work, and nothing will more assist them in understanding and designing work than to see the jobs actually constructed by others, as in this case, and to study their good and bad points, follow out the operation of the system, understand its reasons and devise changes to produce certain effects or remedies. Such suggestions should be criticized by others, some of whom may have had similar cases in their own experience, and can describe their own solution or approve or object to a proposed one.

Such hints from practical men are interesting and may be valuable to the wisest; they raise live questions and show real interest, progress and pride in creditable work.

Our columns are open for such communications, and we invite our observing, thinking readers to write whenever they see an interesting point; it may be plain to them and puzzling to others, or the reverse; no matter how rough the pencil sketch or diagram, or how brief the description, or whether or no the sketch needs description. Do not waste time and labor on scale drawings or elegant and grammatical writing, the facts and practical ideas are the points desired; our draughtsman can make the drawings clear and accurate, and the editor can easily smooth and correct the language.

If a detail or a system is wrong or unsatisfactory, so much the more interesting; far more is to be learned by mistakes than successes.

Our correspondent, who signs himself T. H. S., Kansas City, Mo., writes: "Inclosed I send you a tracing of the system of plumbing just completed by Mr. A. Grey, in a private house, where all the trap vents V V, etc., are carried to foot of stack A, which has a steam coil intending to promote circulation. The local vents L L, etc., from the water-closets and H from a grease trap open into a brick flue F.

"I would like to hear what other master plumbers and journeymen think of the system."

HEATING AND VENTILATING SCHOOL-HOUSES.

(Continued from page 171)

In the paper of Mr. Theodore P. Perkins an account was given of what was accomplished at Lynn, Mass., during the last five years in ventilating several primary and grammar school buildings under the general direction of Dr J. G. Pinkham, of the School Board. Mr. Perkins furnished more or less advice for all the improvements here mentioned.

The Chase Avenue school-house, at West Lynn, although modern and well built, had no efficient airing appliances, and chemical analysis of its air, when in use, showed $\frac{29}{10000}$ of carbonic acid, a greater proportion than in any other building examined. This fact, and the testimony of the noses of persons interested pointed to dangerous organic contamination, and alterations were resolved upon, following the general method described by A. C. Martin, architect, in the report of the Massachusetts State Board of Health for 1871.

The old chimney in the rear wall was torn down and a new one built in its place, with two plain flues in it each two feet square, the chimney being covered with a galvanized iron cap. These outlet flues were connected, by rectangular openings at the levels of the respective floors, with platforms about eight inches high, two in each room, running from the chimney each way along the rear wall, then turning and running along the side walls toward the front. One of these platform ducts in each room was cut off by the chimney from direct connection with its proper flue, and connection was made by boxing around the chimney. Twelve rectangular holes in the edges of the platforms, obstructed by iron registers, connected them with each room.

Fresh warm air was supplied through jacketed stoves. The stoves were of the "pyramid" style, about 6½ feet high, 18 inches in diameter at the base and about 15 inches at the top. Each was encircled by a "jacket" or cylinder of galvanized sheet iron, 3 feet in diameter, resting on the floor, and open at the top, the front being cut into for access to the stove doors. The floor boards were cut away inside the jacket, the stove being supported on special strips, and a cold-air duct was built, starting from the space under the jacket and running horizontally through the side wall of the building, to the outer air, the outside opening being protected by a hood and wire netting, and provided with hinged flaps or valves for shutting the air-box when not in use. The stoves were placed near the front of the room in each case, and within a few feet of the side wall, so that the cold-air ducts were short. These ducts were supposed to be large enough to give a full supply of air when only one stove (and therefore only one inlet), was in use in each room. The smoke-pipes in each room were united, and run up through the middle of the chimney flue for that room and through the top of the cap, ending above everything else. Mr. Perkins' attention was first called to this apparatus in January, 1885, when it had been in use some weeks

The Sanitation Committee which had been appointed, seeing that the heat from the stove pipes did not move as much air as was desired, had broken through the *with* or partition between flues, at the base, and put in a kerosene stove to heat both flues, but this device was not working well. A current of air was observed to blow horizontally across the stove, causing the flames to flare, and sometimes to go out, thus adding kerosene fumes to the other malodorous substances in the school-rooms. This air-current was accounted for by the peculiar construction of the chimney-cap, which resembled in general appearance a bird house, having a pitch roof and metal slats on four sides. It was divided by an upright partition, which was virtually a prolongation of the with of the chimney. The wind blowing against this partition was deflected down one flue, and, to get out, had to go up the other flue or into the school-room. It did both, usually.

The upright partition was removed and the blind-slats changed to admit air more freely, but other things remained to be done. The inlets from the platforms into the chimney were, as aforesaid, at the levels of the respective floors, one of them being about 5 feet and the other about 16 feet above the point where most of the heat was applied. There being no chance for air to get in below this point (for the door from the cellar into the chimney was kept closed) it followed that most of the school-room air must go down before it could go up—in other words, there must be in the lower part of each flue two currents, one upward and one downward, or else there must be a downward current in one flue and an upward current in the other, the result in either case being to take away about half the efficiency of the apparatus. This was changed—the high inlets were stopped, all air was carried through 28-inch tin pipes (one of them running through the lower school-room) to the very bottom of the chimney. The oil stove was abandoned, and a small "ring cylinder" cast-iron coal stove was set in the with of the chimney, a foot or two above the point where the foul air entered, the two flues being wholly separated by the stove and brickwork. Again tests were applied, but the draught was still too feeble. Search was made, and it was found that the spreading bases of the large stoves blocked up a large part of the air space in the lower parts of the jackets. Then the bases of the jackets were made flaring, to allow as much air space at those points as in other parts of the air channels, and the fresh air inlets for the lower room were enlarged. Air-meter tests taken just after these changes were made indicated the passage of about 40,000 cubic feet per hour through the lower room, the temperature out of doors being 15° to 20° Fahr., and in the school-room 63° to 66° Fahr. The draught in the upper room was a little less, probably on account of the small size of the fresh-air inlet and increased length and friction in the outlets.

Experience at this building prepared the way for other like enterprises. Three other 2-room primary buildings have since been ventilated on the same general plan; their apparatus differs from that just described in the following particulars:

At the Red Rock Street school-house, in 1886, the chimney flues were built large enough to have 4 square feet of clear sectional area in each, after deducting the obstruction caused by the smoke-pipes, which were of fireclay, and set in the corners. No cellar was under the rear of this building, hence the flue-heating stove was set above the first-floor level, and the foul air came into the chimney just below it.

THE ENGINEERING AND BUILDING RECORD

RED ROCK STREET SCHOOL HOUSE

Experiments at the Chase Avenue building had proved that most of the air was drawn through the platform holes nearest the chimney; therefore no side platforms were built at Red Rock Street, and large openings were made through the brickwork, leading directly from the lower room into the chimney. The foul air from the upper room was carried down through the lower room to the base of the chimney by a 30-inch circular tin pipe. The bases of the jacket were somewhat improved in shape, with perhaps a slight gain in effectiveness. Instead of registers, coarse wire netting, about equal to one inch square mesh, was stretched across all outlet openings, and two wooden slides in each room shut off all the outlets when not in use. The fireclay smoke pipes in the chimney stopped on a level with the top of the brickwork, and a rectangular cap of the "Emerson" type covered the whole. The difference of temperature between the air at the floor level and that at the breathing line (3 feet above floor), ranged from two to seven degrees with outside temperatures 16° to 35° Fahr. The building is of brick, and warm. All who have to do with this school-house pronounce the air to be of exceptional purity. The task of looking after the fires, to keep the temperature of the room even, is, of course, only one of very many others imposed upon the teacher, and in practice, the temperature varies, at times, considerably from the normal of 68° Fahr., being usually too high.

At the Baltimore Street (old) school-house, in 1887, the air supplying and air removing appliances were placed in the same end of the room, following the suggestion of Warren R. Briggs, architect, who states as the result of experiments with models that this plan secures more thorough diffusion of the air. In the upper room, two small jackets were built, one on each side of the new chimney, the cold air being taken just above the projecting base of each stove. In the lower room a double jacket was built, containing two stoves, one or both of which might be fired at pleasure. Separate smoke pipes inside the chimney were dispensed with, the smoke being discharged directly into the large exhaust flues (each about 2 feet square.) No inconvenience from this arrangement was ever reported. The fullest opportunity to test the peculiar features of this building were not granted, as the Board of Aldermen, in its wisdom, saw fit to build a four-room school-house on this site the following summer. The ventilating apparatus of the old building was removed to the Jackson Street building, and worked over into a new one. Some few innovations were adopted here. For lack of space the two stoves with their jackets were set close together in one of the front corners of each room, and there was for each room only one foul air outlet into the chimney; protected by 3-inch iron gratings instead of wire netting. The smoke pipes were run straight from the stoves to the chimney, disregarding the unwritten law which says that they must run level, and parallel to the walls of the room. The fresh air inlet ducts for the lower room were connected, making a continuous pipe, nearly straight, from one side of the building to the other. For the upper room, the duct turned at right angles, and there was an opening in the front wall and another in the side wall.

In 1885 the Ingalls school-house on Essex Street was taken in hand, but the alterations were not radical enough to bring it up to a proper standard, although there was some improvement. The building is almost the exact counterpart of the Shurtleff school in South Boston, containing 14 rooms and a large hall. The old wooden outlet ducts were left in place, but each group of them was capped with a circular Emerson ventilator—rectangular ones would have been better. Eight of these were on the main portion of the roof, which was rather flat, with a large square cupola in the middle, and the other two were on a tower, in front, and were several feet above all the others. Measurements at the room outlets connecting with these two ventilating caps showed a much stronger draught in these than in the others, in high winds; in some cases even the strong draught in one of these caused a reflux in one of the others, both being connected with the same room. Several other minor improvements were made, such as substituting coarse for fine wire netting, etc. Measurements at this building showed as the result of removing a wooden frame strung with ⅝-inch wire netting from each of several foul air outlets, a gain of 25 to 30 per cent. in discharge, which was nearly in proportion to the area gained by the change. This shows how easy it it is to make air-moving appliances inoperative by neglecting a few small details. An air channel is practically only a little larger than its smallest part. Yet Mr. Perkins says that he has lately seen small outlet openings in a school room covered with two screens each—a half-inch mesh inside and a *sixteenth-inch* mesh outside—the two nettings being about one-half inch apart. If fine wire nettings must be used, the size of the openings should be greatly increased. But coarse gratings, especially if they are easily removable, are probably far better.

(TO BE CONTINUED)

C. L. HOTZE, of the firm of Adams & White, lawyers, of Cleveland, O., is said to be at work securing options for the transfer of some of the largest sewer pipe works in America to an English syndicate. Mr. Hotze's plan is to secure options on 19 sewer pipe works and five tile manufacturing companies which he has in view, and sell the companies in the London market. There is no organized syndicate that wishes to buy the works. It is believed that a combination of companies would strengthen and maintain the prices of sewer pipe and prevent future cutting.

REGULATION OF PLUMBING.

A MARYLAND act requires plumbers to get a certificate of competency from the State Board of Commissioners of Practical Plumbing before they can engage in business in the city of Baltimore. According to *Bradstreet's* the Maryland Court of Appeals lately held this act constitutional in the case of Singer *vs.* The State. The court said: "No one questions the right of every person in this country to follow any legitimate business or occupation he may see fit. This is a privilege open alike to every one. His own labor, and the right to use it as a means of livelihood, is a right as sacred and as fully protected by the law as any other personal or private right. But broad and comprehensive as this right may be, it is subject to the paramount right, inherent in every government, to impose such restraint and to provide such regulations in regard to the pursuits of life as the public welfare may require. * * * As to the common and ordinary occupations of life, little or no regulation may be necessary; but if the occupation or calling be of such a character as to require a special course of study or training or experience to qualify one to pursue such occupation or calling with safety to the public interests, no one questions the power of the Legislature to impose such restraints, and prescribe such requirements as it may deem proper for the protection of the public against the evils resulting from incapacity and ignorance; and neither section 1 of the fourteenth amendment of the Federal Constitution, nor article 23 of the Bill of Rights of the Constitution of this State, was designed to limit or restrain the exercise of this power. It is in the exercise of this power that no one is allowed to practice law or medicine, or engage in the business of a druggist, unless he shall have been found competent, and qualified in the mode and in the manner prescribed by the statute; and although the business and trade of a plumber may not require the same training and experience as some other pursuits in life, yet a certain degree of training is absolutely necessary to qualify one as a competent and skillful workman. We all know that in a large city like Baltimore, with its extensive system of drainage and sewerage, the public health largely depends upon the proper and efficient manner in which the plumbing work is executed, and this being so, the Legislature not only has the power but it is eminently wise and proper that it should provide some mode by which the qualifications of persons engaged in that business shall be determined."

BOOK NOTICES.

POOR'S MANUAL OF RAILROADS FOR 1890; By H. V. & H. W. Poor New York; Price, $6.

Poor's Railroad Manual for 1890, the introduction to which was noticed in a recent issue, has just made its appearance. It is the twenty-third annual number of that well-known work, its principal new feature being the introduction of special maps of the leading railroads of the country These maps, 51 in number, have been carefully prepared, and are of considerable interest and value, showing the lines of railroad in the territory covered, and also some of its chief topographical features. The general character of the work, as we had occasion previously to remark, has become so familiar that we need not dwell upon it here to any extent. The railroad statements are arranged in two parts, the first comprising the statements of all the steam railroads in the United States and Canada, and of the chief ones in Mexico, and the second part, or appendix, giving the statements of street railroads and private commercial railroads, State debts and liabilities, officials of steam railroads, &c.

IN 1887 the water supply of Rotterdam became so much infested with the *Crenothrix*, and with other plants and animals, that a commission of investigation was appointed, and new filters and other works built. Dr. F. Dupont and Professor Hugo de Vries studied the growths by means of laboratories arranged at the water-works, and found that the *Crenothrix Kuehniana* was the chief cause of the Rotterdam water supply difficulty. This organism, one of those known as "iron bacteria," had previously been found to be the chief difficulty in connection with the water-works troubles of Berlin in 1878. It is derived from the basins and canals of unfiltered water. Fresh water crustacea also entered the filtered water, and increased very rapidly, the *Asellus* eating the woodwork used in filters and reservoirs.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

For works for which proposals are requested see also the "Proposal Columns,' pages i-ii-191.

WATER.

For Additional Water Items see Proposal Columns.

Springfield, Ill.—The managers of the water-works propose putting down 3½ miles of 30-inch water pipe. They are now using 15-inch pipe. The work will not begin, however, for some time.

Steelton, Pa.—C. W. Traham, Secretary of the Council, writes: "The borough of Steelton has taken no steps whatever in building water-works. A company of persons, none of whom are residents of this place, has taken out a charter to build water-works here. This is all we know definitely. Whether they will ever build water-works remains to be seen. So far as we are informed this company is known as the Steelton Water Company, and has its office in Philadelphia."

Goldendale, Wash.—Town Clerk W. B. Pusley writes: "The city has been bonded in the amount of $12,500. The contract for furnishing all materials, including pump, reservoir and hydrants, has been given to John Corkish, of Portland, Ore. He is to put in the plant complete."

Louisville, Ky.—Reports say that S. J. Hobbs, W. J. Dodd, and others, have incorporated the Domestic Water Works Company to construct water-works, etc. The capital stock is $50,000.

Cannondale, Wash.—A water-works system is to be established at this place by the Cannondale Water Company at an estimated cost of $20,000. Address A. R. Cannon for particulars.

Lee, Mass.—The local water supply is to be improved.

Peru, Ill.—The committee to which was referred the proposition of the Peru Electric Light Company to put in water-works, has recommended that a franchise be granted.

Guthrie, Okla.—It is probable that steps will soon be taken towards improving the local water supply.

Menasha, Wis.—Reports say that this place is to have a system of water-works.

Vinton, Va.—Reports say that the contract for constructing the local water-works plant has been awarded to S. B. Mosby & Company, of Bedford City.

Chicopee, Mass.—The local officials will soon want proposals for 650 feet of 8-inch cast-iron pipe to connect the present water main with the Dwight Company's pumps, and also for laying the same.

Lima, O.—Reports say that there is considerable dissatisfaction over the quality of the local water supply and that steps will soon be taken to improve it.

Sioux City, Ia.—The surveys for the projected water-works plant on the Big Sioux have been completed and estimates will soon be wanted.

Cisco, Tex.—The city will soon hold an election to decide upon a proposition to issue bonds for the construction of water-works.

Brookfield, Mo.—A committee which has been investigating the water-works question has reported in favor of building a system to be under municipal control.

Arlington Heights, Tex.—A water-works system is to be established at this place by the Chamberlin Investment Company.

Decorah, Ia.—The water-works system at this place is to be considerably extended.

Perth Amboy, N. J.—At a mass meeting held here August 16, it was unanimously resolved to submit the question of establishing a system of water-works to a vote of the people at an early date. It is proposed to bring the water from Aguan Park, near Metuchen. For further information, address Mayor E R Pierce, as above. City Clerk James S. Wright writes: "The Council is taking steps towards the adoption of a public act which will authorize them to provide a supply of pure and wholesome water for the citizens."

Lebanon, Pa.—It has been decided by those in charge to take immediate steps towards improving the local water supply.

Brookville, Ind.—The people of this place are pushing a movement to establish a water-works system.

Gallatin, Mo.—Specifications, etc., are being prepared by S. T. Haynes for a system of water-works to be established at this place.

Beeville, Tex.—This place is to have a system of water-works. For particulars address Mayor A. C. Jones, as above.

Oxford, N. C.—The city will hold an election at an early date to decide upon the proposition to issue $50,000 of bonds for the construction of water-works.

Conneaut, O.—This place is to have a system of water-works. There will be eight miles of mains, 75 hydrants, two compound duplex pumping engines, two 70-horse-power steel boilers, and a stand-pipe 20 feet in diameter and 100 feet high. Water will be taken from a driven well system on the shore of Lake Erie.

Trenton, Tenn.—The city officials have finally decided, by a popular vote, to issue $20,000 in bonds for the construction of water-works.

Keithsburg, Ill.—According to numerous reports this place is to have a water-works system.

Coldwater, Mich.—The question of bonding the city to the amount of $70,000, for the construction of water-works, was voted on August 18, 1890, and carried.

Lindsay, Can.—Reports say that New York parties have made a proposition to put in water-works at this place. It is proposed to take a supply from artesian wells.

Pueblo, Col.—The Pueblo Water Company has been incorporated here by H. J. Fitch and others. The objects include the laying of pipes in Bessemer and Pueblo. Capital, $300,000.

Modesto, Cal.—At a joint meeting of the Modesto and Turlock irrigation directors, held August 9, it was decided to build a joint dam 90 feet high in the Tuolumne River, 1,800 feet above the Wheaton dam, for the use of both districts. The engineers of each district will submit plans for a masonry dam, the best plan to be accepted by the boards in joint session. The amount of water to be diverted by each district is upon the basis of the acreage of the districts.

Toledo, Ia.—The people of this place have voted to bond the town in a sufficient sum to enable establishing a water-works plant.

Fort Worth, Tex.—It is probable that the construction of the projected water-works system for this place will soon commence.

East Providence, R. I.—The matter of granting a franchise to the Riverside Water Company, to furnish water for domestic and general use, was considered at a special meeting August 18, and indefinitely postponed.

Iona, Mich.—City Clerk W. H. Hearsey writes: "This city has ordered survey plans and specifications for a reservoir of 500,000 gallons capacity. I do not know whether it will be built or not."

Gouverneur, N. Y.—L. J. Richardson, of Cortland, has received the contract for building the new water-works plant at this place at $53,000. The total estimated expense of the construction, including engineering, is $59,800. The water tower will be 30 feet in diameter and 40 feet high.

Centerville, Iowa.—Reports say that this place is to have a water-works system.

Tacoma, Wash.—The Tacoma Mill Company of this city, has decided to shortly increase its water supply, and with this end in view, the plans are being prepared for a reservoir, to hold 600,000 gallons, which the company proposes to erect. The plans are being drawn in the office of Assistant Engineer A. Rydstrom. It is proposed to so construct the reservoir that the water supply may be derived from the springs on the bluff top. The reservoir will cost in the neighborhood of $250,000.

Mobile, Ala.—Our correspondent writes: "The contract for building the water-works in Shelby Ville, Shelby Co., Ala., has been let to H. Merrigold, of Anniston, Ala. The water will be taken from Freestone Springs in neighborhood. Its system will consist of nine miles of 12, 8 and 6-inch pipe; one 2,500,000 Dean pump, and one 1,500,000 Worthington pump; stand-pipe."

Elroy, Wis.—City Clerk E. S. Willey writes: "The city will establish a system of water-works, work will not be begun, however, until early next spring. This is on account of a deficiency in the charter, which will be amended when the State Legislature convenes."

Brooklyn, N. Y.—The Aldermen have adopted the report of the Water and Drainage Committee giving City Works Commissioner Adams power to go ahead and spend $700,000 on improvements in the water supply in the portion of the city bordering on the high ground about Prospect Park.

Cairo, Ill.—Thos. W. Gannon, Superintendent of the Water-Works, has been awarded the contract for building sewers on certain streets.

Independence, Mo.—The Superintendent of the Independence Water Company writes: "We intend to change our source of supply. Instead of pumping direct from the Missouri River, we will try and get a supply from dug or driven wells, near the river. We will erect a new pumping plant; will need two duplex pumps ¾ million gallons each, with the necessary steam plant to operate them, a new stand-pipe 150 feet high by some 15 to 20 feet in diameter, about two miles of 14-inch and some three miles of 4-inch mains, with the necessary valves, etc. While we have been getting rough estimates as to the probable cost of these improvements, nothing definite will be done until after September 4, when an election will be held by stockholders for the purpose of increasing the bonded indebtedness from $60,000 to $100,000."

Palo, Mich.—It is proposed to issue bonds for the construction of a system of water-works at this place.

Iron Mountain, Mich.—The Iron Mountain Water-Works Co. has been incorporated; capital, $75,000.

Water-Works.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Canton, O.; Quebec, Ont.; Gainesville, Ga.; Norwalk, Conn.; New York City; Hoboken, N. J.; Algona, Iowa; Pasco, Wash.; Franklinville, N. Y.; Newport, Ky.; Allegheny, Pa.; Austin, Tex.; Madison, N. J.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

Findlay, O.—City Clerk Marion G. Foster writes: "Sewer District No. 1 has been established and the Board of Improvements has recommended the immediate construction of the same. The necessary ordinance providing for the construction will probably be passed by the Council soon. The system consists of six main sewers and about 60 sub main sewers."

Joplin, Mo.—Messrs. Rosewater & Chrysler, civil engineers, Omaha, Neb., have completed plans and submitted their report with estimates of a system of sewerage for the city of Joplin, Mo. The plans were approved and about $20,000 will be expended on work upon the system this season.

Butte, Mont.—The sum of $70,000 has been voted for additional sewers at this place.

Columbus, Ga.—The officials have decided to issue bonds for the construction of a system of sewers.

Williamsport, Pa.—Reports say that extensive improvements are to be made to the local sewerage plant.

Braintree, Mass.—Reports say that considerable sewer work is to be done at this place.

Little Falls, N. Y.—Considerable sewer work is to be done at this place. Address the Town Clerk, as above.

Batavia, N. Y.—A new system of sewerage is to be introduced at the Batavia Institution for the Blind. The State has appropriated $12,500 for it. It is expected that the swamp near the institution will be drained

Ashland, Wis.—The City Council on August 12 voted the sum of $30,000 to be used in making sewer extensions.

Kansas City, Mo—An ordinance providing for the establishment of a sewer district that will drain over 600 acres of the city lying between Eighteenth Street and Forest Avenue, Thirty-first Street and Highland, will be introduced at the next session of the Common Council. It has just been passed upon favorably by the Board of Public Works, and is now ready for the action of the two houses. The estimated cost of the main and lateral sewers in the three districts is $100,000.

Brunswick, Ga.—Important steps will soon be taken towards establishing a system of sewers at this place.

Sewers.—See our Proposal Columns for information regarding sewer construction at the following places: Danbury, Conn.; Wilmington, Del.; Cleveland, O.; Key West, Fla.; New Haven, Conn.; Vancouver, B. C.; Para, Brazil.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

St. Paul, Minn.—There is a proposition to bridge the Omaha tracks at Payne Avenue with a bridge of iron in place of the present one of wood.

Lyons, Iowa.—The Lyons and Fulton Bridge Company will build a highway bridge over the Mississippi River between Lyons, Iowa, and Fulton, Ill. The structure will be 2,650 feet long from end to end of approaches, the river being crossed by one 200-foot span, three 330-foot spans, and one 360-foot channel span, all on masonry piers, the superstructure to be of steel. C. F. Loweth, of St. Paul, Minn., is the Consulting Engineer for the bridge company. Contract has recently been let to the Chicago Bridge and Iron Works, for the entire work.

Boston, Mass.—The Pittsburg Bridge Company has secured the contract for the Federal Street bridge, for $102,180.

Worcester, Mass.—It is proposed to erect a bridge over the tracks at Lincoln Square, at this place. City Engineer Allen can furnish particulars.

Knoxville, Tenn.—The Cherokee Land Company has a project on hand to open up a new tract of property, and among the other improvements necessary will be an iron bridge, on which it is proposed to expend the sum of $100,000. Gen. J. C. J. Williams, the President of the company, can furnish details.

St. Joseph, Mich.—Mayor Scott, of this town, can give information of a proposed bridge over the St. Joseph River at the foot of State street. The Cincinnati, Wabash and Michigan Railroad are interested.

Evansville, Ind.—Auditor James D. Paine writes: "All bids were rejected for constructing a wrought iron bridge over Pigeon Creek. The Commissioners will re-advertise in the near future."

Iron City, Tenn.—A scheme to place a bridge over Brush Creek is being discussed by the local officials.

Louisville, Ky.—It is proposed to construct an iron highway bridge over Kentucky Street at the expense of the city and the Louisville and Nashville Railroad Company.

Dallas, Tex.—The City Engineer has made estimates for an iron bridge across Turtle Creek on Lemon Avenue. The City Council has been asked to build a bridge across Turtle Creek at Peak Street.

Bristol, Tenn.—Bonds in the sum of $50,000 will be issued at this place for the purpose of erecting five iron bridges on numerous streets.

Tyler, Tex.—The Naches River is to be bridged at this city.

Alexandria, La.—A new railroad bridge is to be built across the Red River at this place at about 200 yards below the mouth of the Rigolette River. The structure will be about 800 feet long, and the piers will be of iron filled with concrete.

Weston, W. Va—Plans have been accepted by the County Commissioners of Suar's County for a new iron bridge, 36 feet wide and 195 feet long, across Hughes River at this place. The Commissioners will soon advertise for bids.

Augusta, Ga.—Reports say that proposals will soon be wanted by the North Augusta Land Company for the new bridge which it proposes to build over the Savannah River at this place.

Brooklyn, N. Y.—The Lewis & Fowler Girder Company, of this city, has been incorporated with the Secretary of State, to acquire, by purchase or otherwise, and to use and dispose of letters patent, licenses, etc., for and in respect of inventions relating to girder rails, etc., and to manufacture and sell these rails. The capital stock is $300,000, and the trustees are John W. Fowler and others.

Lynchburg, Va.—The City Council has ordered the construction of an iron bridge across Blackwater Creek.

St. Paul, Minn.—Reports say that the Mississippi River is to be bridged by the Great Northern Railroad, at a point below the proposed Broadway edifice, in this city.

Detroit, Mich.—The special Council Committee on Bridges will meet August 25, with the City Councilor and City Attorney, to consider the proposition of the Michigan Central Railroad Co. to share the expense of the construction of an iron bridge over their tracks on Baker Street.

Boston, Mass.—The following proposals for the Federal Street bridge draws were opened August 20 by the Engineering Department: Pittsburg Bridge Company, Pittsburg, Pa., $10,218; D. H. Andrews, Boston, Mass., $11,998. The contract was awarded to the Pittsburg Bridge Company.

Chicago, Ill.—Reports say that proposals will soon be wanted for the erection of the substructure of the Canal Street bridge over the South Branch. The estimated outlay is $25,000.

Duluth, Minn.—The contract for constructing the iron work of Howard's Pocket bridge has, it is reported, been awarded to the King Iron Bridge and Manufacturing Company, of Cleveland, O., at $27,100.

Paola, Kan.—Reports say that the County Commissioners of Miami County have advertised for proposals to build bridges at the following places: Across the Marais des Cygnes north of Osawatomie, across the Wea, east of Paola, and at Whiteford, on Bull Creek, in North Marysville.

Pittsburg, Pa.—Reports say the Fifth Street Bridge Company has been formed in this city for the purpose of erecting a bridge and viaduct from the foot of Fifth Street to Stockton Avenue.

St. Paul, Minn.—The Chicago, St. Paul, Minneapolis & Omaha will probably replace the wooden bridge over its tracks on Payne Avenue with an iron structure.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: Marble Falls, Tex.; Rome, N. Y.; Brooklyn, N. Y.; Pineville, Ore.

NEW DEPOTS.

St. Joseph, Mich.—The Cincinnati, Wabash and Michigan Railroad will build a new depot here, also round-house and other buildings.

STREET-WORK AND PAVING.

Ashland, Wis.—The City Council has authorized the paving of numerous streets with cedar block.

New Brunswick, N. J.—Considerable important paving work is to be undertaken in this city. The City Clerk can furnish particulars.

Toronto, Can.—There is a project in this city to make improvements in paving, and also to construct several tunnels, and the entire cost of the work is estimated at $186,408. Alderman Hewitt, Chairman of the Committee on Street Paving, can furnish information.

Media, Pa.—Considerable street paving is to be done at this place.

St. Paul, Minn.—A committee from the Arlington Hills Citizens' Union recommends the paving of numerous streets

Toledo, O.—Paving contracts with fire brick have been awarded to Claflin & Miller, at $14,340.45, and Wm. McMahon with cedar blocks, at $4,762.39.

Chattanooga, Tenn.—The following bids for paving were opened by the Board of Public Works on August 14, 1890: For Market Street, Gen. P. M. B. Young bid $2.74 per square yard for sand and $3 30 for concrete; M. E. Maher, $2.69 for sand and $3 35 for concrete; Venable Bros., $2.59 for sand and $3.40 for concrete. For Carter Street, the Southern Construction Company bid $2.40 per square yard, 10 per cent. retained, or $2.34 with all money paid and a five years' guarantee given. General Young's bid was $2.25 per square yard with 10 per cent. retained. For Montgomery Avenue, Southern Construction Company bid $2.42 per square yard, and General Young, $2.30. The amount of paving to be done in all three streets covers about 38,000 square yards.

Johnson City, Tenn.—A meeting was held August 15, to consider the issuance of $50,000 worth of bonds for streets and schools.

Scranton, Pa.—Considerable paving is to be done in this city at an early day.

South Norwalk, Conn.—The sum of $10,000 has been appropriated for paving purposes at this place.

GAS AND ELECTRIC-LIGHTING.

St. John, N. B.—The St. John Electric Light Company has been organized at this place with a capital stock of $50,000, for furnishing lights to cities, towns, etc.

Laconia, N. H.—Improvements are to be made to the local electric lighting plant, at a cost of $10,000.

Morton, Pa.—The Faraday Electric Light Company will erect a plant as soon as a site can be secured. The company expects to supply Secane, Swarthmore and Moore's station.

Portland, Me.—The Orient Electric Company will establish a plant at this place. Capital stock, $100,000. Address Robie Blake, Cornish, Me.

Huntington, Ind.—The Huntington Fuel and Light Company has been incorporated here. Capital stock, $25,000. John K. Brice, Frank D. Townsend and others are interested.

Chester, S. C.—At a recent town meeting it was voted to authorize the Council to contract for a system of electric street lighting at a cost not exceeding $2,000 per annum.

Winchester, Tex.—It is proposed to establish an electric light plant at this place.

Seneca Falls, N. Y.—Immediate steps will be taken to rebuild the electric light plant at this place which was recently destroyed by fire.

McKeesport, Pa.—The Enterprise Light, Power and Heat Co., has been organized here, with a capital of $100,000, to do business at Reynoldstown. The officers are: President, J. E. White; treasurer, Thomas Reynolds.

Beloit, Wis.—The Common Council has contracted with the Beloit Electric Light Co. for thirty 2,000 candle power lights, at $75 a year per lamp, the lights to be run every night until 1 o'clock.

Hollis, L. I.—The Standard Light Co. has been incorporated for the purpose of lighting Hollis and adjoining places. A complete plant is to be established and material will be wanted for a circuit of 200 lights of 20-candle power each. For particulars address E. H. Rath, Corbin Building, New York City. The capital of the company is $500,000.

Milledgeville, Ga.—The local electric light company will double the present capacity of its incandescent system and also add the arc system.

Cohasset, Mass.—Immediate steps will be taken toward establishing an electric light plant at this place.

Eaton, O.—This place is to have electric lights, at an expenditure of $20,000.

Braintree, Mass.—An electric lighting project is being discussed here.

Sheffield, Ala.—The local electric light company is preparing to buy new electric machinery.

Washington, Ga.—A 500 light electric lighting plant is to be established at this place as soon as plans, etc., are completed.

Shelbyville, Ind.—The Indiana Water and Light Co., of this place, is consolidating its electric light and water-works plants. A new building and additional lighting apparatus will be added.

Clinton, Mo.—At a recent meeting of the Common Council it was decided to light the streets of that city with 38 arc electric lights.

Topeka, Kan.—The Johnson Fuel, Gas and Construction Co., has been incorporated here with a capital stock of $200,000. The directors are C. P. Baker, T. D. Cook and others, all of Topeka.

Wellsville, N. Y.—An electric lighting plant is to be established at this place.

Centreville, Iowa.—An electric light plant is to be established at this place.

Canisteo, N. Y.—This place is to have electric lights. For particulars, address Messrs. Bailey & Davis, as above.

Monillton, Ark.—A franchise has been granted to W. J. Stowers and others for establishing, etc., an electric light plant.

Mount Pleasant, Mich.—An electric lighting company has been incorporated here, and a plant is to be established at once. The capital stock is $10,000.

Oil City, Pa.—The city officials will soon want proposals for electric lighting.

Waynesboro, Ga.—The Waynesboro Electric Light Company has been organized here with a capital stock of $7,500. Directors, A. G. Whitehead, P. L. Corker and others.

San Francisco, Cal.—The California Gas, Light and Fuel Company has filed articles of incorporation. Directors, H. B. Smith, Jr., of Alameda, and others. Capital stock, $10,000,000.

Electric Railways.—New electric railways are to be built and improvements are to be made to those already established at the following places: Winnepeg, Man.; Waco, Tex.; Owasso, Mich.; Rochester, N. Y.; Newark, N. J.; Portland, Ore.; Salem, Mass.; Braintree, Mass, Memphis, Tenn.; Paterson, N. J.; Knoxville, Tenn.; Norfolk, Va.; Hastings, Neb.; Beatrice, Neb.

RAILROADS, CANALS, ETC.

Springfield, Ill.—The Citizens' Street Railway Co., of which Charles F. Herman is secretary, will spend $150,000 or more in an electric plant, and the road will be run by electricity.

Marquette, Mich.—The Marquette and Presque Isle City Railway Company has been incorporated, capital $25,000.

Holland, Mich.—The Holland South Shore Railway Company has been incorporated; capital $60,000.

INDUSTRIAL.

Aberdeen, S. D.—At a special election held here it was decided to issue city warrants to the amount of $50,000, to aid in the construction of a railroad from Oakes to Aberdeen and Pierre.

San Francisco, Cal.—The San Francisco Gas Light Company will build a wharf (for the reception of coal cargoes) at the foot of Second Street. M. E. Manson, C. E., can give particulars.

Coatesville, Pa.—Huston & Co. contemplate erecting a steel plant at this place.

MISCELLANEOUS.

Springfield, Ill—C. W. Shinn, architect, has completed plans for a boiler shop, to cost about $35,000. A. L. Ide and E. A. Wilson are interested. Plans will also be made for a furniture factory, in which the same parties are interested.

NEW CORPORATIONS.

Madison, Wis.—The Wisconsin Bee Line and West Superior Railroad Co. has been incorporated. The object of the company is to construct a line from Milwaukee to West Superior, a distance of 360 miles. The capital stock is $3,000,000. The incorporators are C. D. Smith, F. M. Fox, R. O. Bigford, and others.

BIDS OPENED.

Fairbury, Neb.—The contract for building the Jefferson County Court House was awarded August 12 to J. C. Holland, of Topeka, at $52,000. The building is to be of stone and is 90 by 106 feet.

Sherbrook, N. Dak.—The following bids for furnishing 26,000 common or slop bricks were received by L. C. Goplemd, Auditor, August 12: W. P. Alsip, Grand Forks, N. Dak., $235; W. I Warrey, N. Dak., $11 per M., or $286.

Milledgeville, Ga.—T. O. Brown, of Augusta, Ga., has been awarded the contract for the erection of the Girls' Normal Industrial School, at $38,000. Messrs. MacMurphy & Story, of Augusta, are the architects.

Boston, Mass.—The following proposals for the construction of sections 8 and 9, Metropolitan Sewerage System (East Boston), and Sections C and D (Brighton), all in this city, were opened by the Board of Metropolitan Sewerage Commissioners, August 13:

Section 8—Main Sewer—East Boston.

VICKSBURG, MISS.—The contract for roofing, plumbing and gas fitting of the new Natchez Hotel has been sublet to H. B. Bruser, of this city, at $80,000.

INDIAN ORCHARD, MASS.—The contract for the brickwork on the additional plant for Chapman Valve Manufacturing Company, Jason Giles, General Manager, has been awarded to D J Curtis, of Springfield, at $8,000.

ELLIS ISLAND, N. Y.—Frank Rinschler, of Stapleton, August 20, received the contract for building the masonry and making the foundation for the main immigration station on Ellis Island. His bid was $13,747. The contract for making the cribwork, with the exception of the breakwater, was awarded to Warren Rosevelt, of New York City, for $37,000.

SPRINGFIELD, MASS.—The following proposals for the erection of the Pynchon School has been received by the city property committee: J. S. Sanderson, $30,845; J. B. Walls, $30,500; Jerry Shea, $29,335; L. H. Scott, $28,877; L. Strong, of Chicopee, $27,641; Patrick Benston, $27,625. The contract has not yet been awarded.

CAMDEN, N. J.—The Board of Education has awarded the contract for the new schoolhouse on Newton Avenue to City Assessor John Corbett, at $19,281.79. The lowest bid was that of Charlton H. Sayre, $18,127, but it was informal. The contract for building an extension to Mt. Vernon school was also awarded to Corbett, at $5,598 63.

Oakland st, n e cor Greene st, 4 fr (br filled) stores and tens; cost, $4,000 each; o, James Kelly; a, F Weber; c, J A and W H Port, m, C C Gately.

S s S 3d st, 100 w Hooper st, 2 br tens; cost, $6,000 each; o and b, J W Lamb & Son; a, A W Lamb.

S s N 1st st, 75 Wythe av, 1 br storehouse and stable; cost, $8,000; o, Thomas W Kiley; a, W H Gaylor.

BETHLEHEM, PA.—Wall and Mable, 5 br and terra cotta dwells; cost, $14,000; o, G H Myers; a, A W Leh; b, no contract let.

BOSTON, MASS.—Knapp st, br mercantile, alteration and extension, cost, $53,000; o, Cobb, Bates & Serxa; a, Hartwell & Richardson; b, McNeill Bros.

Ruthven st near Elm Hill av, fr dwell; cost, $12,000; o, M P W Jones; a, J W Beals; b, Ourish & Rich.

Harbor View st, fr dwell; cost, $7,000; o and b, Hugh H Smith; a, E N Boyden.

Clinton st and N Market st, fr rebuild (fire); cost, $40,000; o, Clinton Market Corps; b, J J Shaw.

43 Central wharf, internal alteration; cost; $6,000; o, J D Williams, Treas; b, S S Goodwin.

436 Meridian st, fr dwell; cost, $7,500; o, S M Stevens; a, I S Eastman; b, Hatt & Rogers.

Cambridge st near Dustin st, fr dwell; cost, $7,000; o, Henry P Kennedy; a, T L Smith; b, James Muldoon.

Conant st and Bumstead lane, fr dwells; cost, $7,500; o, Thos Toohey; a and b, J H Pierce.

BRADDOCK, PA.—A church, to cost, $15,000, is to be erected at this place. Address the pastor of the Disciple Congregational Church, as above.

CAIRO, ILL.—The building of a new City Hall is proposed, as one is badly needed in Cairo.

CHAMBERSBURG, PA.—A hospital bldg is to be erected at this place by the Children's Aid Society. Address Dr J S Hull, as above.

CHICAGO, ILL.—Winter nr 50th, br flats; cost, $35,000; o, Jno S Thomas.

Packers av and 46th, beef house; cost, $30,000; o, T E Wells & Co; b, William O'Brien.

2469 n s Paulina, br dwell; cost, $8,000; o, R J Gannell.

4938–40 Drexel boul, br dwell; cost, $65,000; o, Dr J A M'Gill; a, H Ives Cobb; b, Angus & Girdele.

4119 Vincennes av, br flats; cost, $8,000; o, F N Nelligan; a, W W Myers.

5121–23 Kimbark av, br dwell; cost, $8,000; o, C C Conover; a, N Sprague.

538 46th, br flats; cost, $8,000; o and b, Z F Ringer; a, N H Smith.

4823–29 Drexel boul, br dwell; cost, $75,000; o, Albert Wisner.

170–72 92d, br store and flats; cost, $10,000; o, Hermann Derwedden; a, T Tretholm; b, Daegling & Co.

3300 Wallace, br flats; cost, $11,000; o, Jno Hackett; a and b, C Kerbach.

927 w Adams, br dwell; cost, $8,000; o, Jas McGraw.

1113–15 Lawndale av, br dwell; cost, $13,000; o, Bonney Bros; b, F C Porter.

3836 Wabash av, br flats; cost, $8,000; o, Geo E Core; a, R G Pentecost; b, T A Beckett.

351 Webster, br store and flats; cost, $8,000; o, Frank L Shellenberg.

1430–38 W Congress, br flats; cost, $30,000; o, Elizabeth Cooley.

3646 Michigan av, br dwell; cost, $16,000; o, M Gimbel; a, O W Marble; b, O Anderson & Co.

504–10 Armitage av, br store and flats; cost, $8,000; o and b, Aug Wentel; E Clark.

3803 Vincennes av, br addn; cost, $11,000; o, J R Crocker; b, Williams & Stacy.

1291–1301 Taylor, addn to factory; cost, $20,000; o, Jas A Piper; b, Mortimer & Barr.

BUILDING INTELLIGENCE.

CHICAGO, ILL.—2713 Indiana av, br flats; cost, $12,000; o and a, Jas A Tham; b, A Collender.

Cor Washington boul and Peoria, St Mary's Mission House, adjoining Cathedral; cost, $15,000; o, Episcopal Bishop of Chicago; a, Treat & Foltz.

La Salle and Adams, 2 additional stories to office bldg; cost, $125,000; o, Home Insurance Co; a, W L B Jenney.

951 Ogden av, br flats; cost, $12,000; o, P Bretchmer; a, A J Pott.

Edison Park, lodge bldg; cost, $9,000; a, F Ahlschlager.

Hoyne and La Moyne av, br dwell; cost, $20,000; a, H T Kley.

W Harrison, west of Oakley av, br flats; cost, $12,000; o, Thos Gault; a, W L Carroll.

Michigan av near 12th, 8-story apartment house; cost, $100;000; o, E O Russell; a, Fred Baumann and J K Cady.

2332–48 State, br store and flats; cost, $40,000; o, Jonathan Clark; a, Howe & Shelton.

Lake Shore Drive, st and br dwell; cost, $25,000; o, Hiram N Smyth; a, as above.

Cor Dearborn av and Erie st, 2-story addition to Mentone flats; cost, some $40,000; a, L G Hallberg.

Oakenwald av near 45th st, br dwells; cost, $45,000; o, R F Keith; a, as above.

Park av and Hoyne, br and st dwell; cost, $26,000; o, J J McGrath; a, as above.

1201–23 N Western av, br flats; cost, $160,000; o, Geo L Marchie; a, Perley Hale; b, Wm Zullsdorf.

1027 W 19th st, br flats; cost, 810,000; o and b, Frank Kneaba; a, Anton Charvat.

3312 Indiana av, br dwells; cost, $8,000; o, Hy Heflor; a, Furst & Rudolph; b, A Minor.

225 S Morgan st, br flats; cost, $8,000; o, J L Brown.

123–25 LaSalle av, br office bldg; cost, $60,000; o, Watson estate; a, Bowman & Cody; b, Barney & Rodatz.

9–18 Huron st, br factory; cost, $90,000; o, Jose Tilt; a, M P Bell; b, same as above.

160 bldgs costing less than $7,000 each.

COLUMBUS, O.—State st, br and stone church; cost, $25,000; W H Slade, trustee. 10 dwells; cost, $27,000.

DECATUR, ILL.—Henry F Starbuck, architect, Chicago, Ill., has completed plans for 2 churches, one a Presbyterian, to cost $75,000, and the other an Episcopal, to cost $30,000. R G Young has been awarded contract for the construction. The plumbing has not yet been contracted for.

R L Dickinson, architect, has completed plans for a residence for J S C Cussins, of the same place.

DENVER, COL.—S 5th st, bet 12th and 13th avs, br brewery; cost, $100,000; o, J P Dostal; a, Hiershuer & Hiershuer.

McCollough Addition, br dwell; cost, $8,000; o, Thomas Furgeson.

McCollough Hill Addition, stone dwell; cost, $10,000; o, William Geddes.

McCollough Hill Addition, stone dwell; cost, S10,000; o, David Seerie.

DETROIT, MICH.—Cor Chene st and R R, 4 story br mfy bldg; cost, $40,000; o, Detroit Radiator Co; a, Scott, Kamper & Scott.

Cor Cass and Middle sts, 4 story br hotel, cost, $15,000; o, Wm B Perkins; a, Donaldson & Meier.

Jefferson av, bet Dubois & Chene sts, 2½ story br and s res; cost, $14,000; o, Michael Martz; a, Gordon W Lloyd.

S e cor Michigan av and 4th st, block of 4 4-story br stores; cost, $12,000; o, Thos Kennedy; a, A C Varney & Co.

Junction av, 2½ story br and s res; cost, $7,000; o, Chas Jenkins; a, Spier & Rohns.

1134–6 3d av, 2 story br and s res and barn; cost, $7,500; o and a, H W Holcomb.

Cor Canfield and McDougall avs, br and s church; cost, $30,000; o, St Elizabeth R C Soc'y; a, Donaldson & Meirer.

ERIE, PA.—A seminary, to cost $40,000, is to be erected at this place. Address Rev. Father Thomas A. Carey, as above.

BUILDING INTELLIGENCE.

GREENSBURG, PA.—The Committee on Public Buildings and Grounds has reported favorably a bill appropriating $50,000 for a public building at this place.

HOLYOKE, MASS.—Plymouth st, 16 tens, br block; o, Le Clair & Labourin; a, G B P Alderman.

HYDE PARK, ILL.—Maher & Corwin, architects, of Chicago, will make plans for a $100,000 hotel for A F Shuman. Steam heat and electricity will be used.

McKEESPORT, PA.—A brewery, to cost $100,000, is to be erected at this plac.

MERIDEN, CONN.—Crown st, apart house, 2 families, 24 rooms; cost, $8,000; o, John Ives; a, H M Jones; b, not let.

MINNEAPOLIS, MINN.—2714–22 N Wash av, br flats; cost, $30,000; o, J Hanson.

MONTCLAIR, N. J.—Frame dwell; cost, $7,500; o, I Lymore Crane; a, George W Delenha; b, Wm H Dewitt; m, George Booth.

NATCHEZ, MISS.—Hotel; cost, $85,000; a, McDonald Bros; b, M T Lewman & Co.

NEW HAVEN, CONN.—East st, near Greene, br storehouse; cost, $30,000; o, L Candee & Co; b, Smith, Sperry & Treat.

Congress av, near West st, fr dwell; cost, $8,000; o, Fritz Leah; b, Bohen.

Park st, near Chapel st, br dwell; cost, $8,000; o, Elizabeth Thompson; b, John Leonard.

Goffe st, near Webster st, br dwell; cost, $7,500; o and b, H F Warner.

Silver st, br freight house; cost, $15,000; o, Housatonic Railroad Co.

OAKLAND, CAL.—The Board of Public Works has instructed Architect Matthews to draw up the plans and specifications for a new $18,000 engine house.

PITTSBURG, PA.—It is reported that the Order of American Mechanics will erect a new building on Penn ave, at a cost of $100,000.

RED BANK, N. J.—Articles of incorporation have been filed by Edward F. Stokes, proprietor of the Hoffman House in New York, and others, as a company to erect a hotel at Red Bank. The capital stock subscribed is $750,000.

SELLERSVILLE, PA.—The Sellersville Improvement Company will erect eight dwellings at this place.

SHORT HILLS, N. J.—A casino, to cost $20,000, is to be erected at this place. Address the Postmaster.

ST. LOUIS, MO.—Bell av and Whittier st, br dwell; cost, $7,000; o, Mrs L W Green; b, T J Kelly.

Waverly pl and Geyer av, br dwell; cost, $7,500; o, A Herthel; b, A Wieden.

Cambria and Congress sts, br dwell; cost, $7,000; o, H Dorste; b, F Mueller.

Olive st and Newstead av, br dwell; cost, $7,500; o, Sam T Bleyer; b, J H Keefe.

ST. PAUL, MINN.—Iglehart near Prior, 4 2-story fr dwell; cost, $20,000.

Lowell near Mackubin, addn to school; cost, $25,000; o, Board of Education.

WHEELING, W. VA.—15th st, county jail of br, s and iron; cost, $70,000; o, County; a, M Giesy; b, Murray Bros.

Market st, br, fr and slate market-house; cost, $7,000; o, City; a, E Franzheim; b, not given.

WORCESTER, MASS.—Jackson st, br ten block; cost, $12,000; o, J A Colvin; a, Barker & Nourse; b, W Cheney.

YORK, PA.—27 East Market st, Trust, Real Estate and Deposit Co; cost, $25,000; o, Trust, Real Estate and Deposit Co; a, J A Dempwolf; b, contract not let.

BUILDINGS.—There is not over $7,000 in value to report at the following places: Geneva, N. Y.; Harrisburg, Pa.; Charleston, S. C.; Springfield, O.; Ogdensburg, N. Y.; Wilkesbarre, Pa.; Dennison, O.; Saginaw, Mich.; Dayton, O.; Waco, Tex.; Canton, O.; Clinton; Iowa; Pasadena, Cal.; Topeka, Kan.; Galveston, Tex.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22. NUMBER 13.
PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.
NEW YORK, AUGUST 30, 1890.
LONDON, SEPTEMBER 13, 1890.
SINGLE COPIES, TEN CENTS. Subscription, $4.00 per year in advance, post paid. } IN AMERICA.
Subscription, 25*s*. per annum in advance, post paid } IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street*, *New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.

25*s*. in GREAT BRITAIN. Other Foreign Countries $6.

Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $6; China, Japan, Sandwich Islands, Mexico and Cuba, $6; South America, $6.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

THE INTERNATIONAL NAVIGATION CONGRESS AND ITS RECOMMENDATIONS.

AT the Manchester meeting of the International Navigation Congress, which was attended by official delegates from nearly all of the European states and was opened by Sir Michael Hicks-Beach, the President of the Board of Trade, the following recommendations, briefly stated, were agreed to by the delegates, after much discussion, as representing the chief results at which they had arrived.

The construction and maintenance of waterways should be the object of earnest attention from the State, as they form a valuable means for transportation at low cost. To secure this, uniform dimensions of locks are necessary. The co-existence of waterways and railroads is desirable, because the one is complementary to the other, and, from a broad point of view, the industrial and commercial development which will result from perfecting both must, in the end, profit each. The great value of waterways and the fact that they are feeders of, and supplementary to, the railroads justifies the State in assisting their construction and maintenance, so as to encourage through traffic at low rates.

The interdependence of the two methods of transportation has possibly never been thoroughly recognized by any of our railroad managers, except the late Dean Richmond, who, when President of the New York Central Railroad, refused to countenance a raid on the Erie Canal, saying he had rather increase its depth and usefulness, pointing out that the best paying railroads of the country were parallel to the natural or artificial navigable water courses. On the contrary, the testimony of Messrs. Fink, Blanchard and others, showing the effect of water-borne freight in reducing railroad freights, the combined Erie Canal and Lake traffic influencing freight rates to the Gulf, has appealed strongly to those interested in railroad securities, and they, with the aid of bankers, who never handle the money expended in the improvement of our rivers and harbors, have developed an immense amount of newspaper and other hostility to our River and Harbor bills.

In Europe, and more particularly in England, where railroads are neither so well nor cheaply managed as here, and the freight rates are much higher—two to two and a half times higher in England—the demand for the aid of cheaper water rates is more general than here, and, as our readers know, the improvement of rivers and the construction of large canals progresses faster and on a more satisfactory basis than here. One reason for this is that the plan of improvement, when once adopted, is provided for, so that the works can be carried out to the best advantage and at the minimum cost, instead of by the method of yearly appropriations, which, being at the mercy of every objecting demagogue, and liable to be withheld at any time, or even withdrawn for a series of years, requires appropriations covering the cost of a new plant for prosecuting the work possibly on an average of once in three or four years all over the country. This is due, in part, to the fact that a new contract is let to expend each appropriation instead of treating each work as a whole.

In addition to the economic questions involved in a discussion of navigable waterways, a great deal of discussion was given to the technical side. One feature in the management of the meeting may be heartily commended to the consideration of the American Society of Civil Engineers. All the papers were printed and furnished to the delegates, so that they were taken as read, and the time of the congress was devoted to an intelligent discussion of their contents.

A GENERAL SUBWAY FOR NEW YORK.

PROBABLY no other matter has more prominently brought the much-discussed need of a general subway beneath the streets of New York to the attention of the public than the recent controversy between the New York Steam Company and Commissioner of Public Works Gilroy.

After a war of words and almost endless correspondence, however, the hatchet has been buried and the work of the company which has called forth so much unfavorable comment will go on as before. New connections will be made as required and old defects will be patched up as formerly, and there is no reason to expect a cessation of periodical, if not almost continual, street excavating.

It is not the Steam Company alone, however, that is responsible for all the street annoyances inflicted upon the New York public in years past. Every corporation having underground pipes or conduits of any kind has been instrumental in contributing more or less to the discomforts, and will necessarily continue to be so until a rational method of accommodating underground conduits has been adopted. It is only a question of time when the general subway, long urged by THE ENGINEERING AND BUILDING RECORD, and designed to give room to all such conduits, will become an even more pressing necessity than it has already shown itself to be. It is only a subway of this kind which will enable inspection and repair of old, and the laying of new, subterranean pipes, without constantly tearing up pavements and damaging one set of conduits while attempting to add to or overhaul another one.

With the idea once firmly impressed, as it must become, that such a subway is unavoidable in the end and that the cost and difficulties of construction are only being multiplied with the lapse of time, there ought to be no hesitation in getting the work under way. Prompt action now would save large additional sums which would have to be expended a few years hence.

THE BRICK BOYCOTT.

THE brick boycott which was recently declared at New York, Brooklyn and Jersey City is, in one respect at least, unique, and its outcome will be of general interest. Briefly stated, the history of the boycott is that the Board of Walking Delegates recently demanded of four firms of brickmakers at Verplanck Point, on the Hudson, that they should discharge all their non-union workmen and employ only union men. On the refusal of the firms a boycott of their brick was ordered, and no union bricklayers or other union workman in New York City dare now touch their brick, and no dealer dare handle it for fear of being boycotted himself.

The interesting part of the matter, however, is that the New York and New Jersey Brick

Manufacturers' Association, of which the four boycotted firms are members, have, in retaliation adopted the union workingmen's tactics, and since August 22 have stopped all shipments of brick to the New York market, and threaten that they will not resume them until the boycott on the Verplanck Point manufacturers is removed. As in the case of the recent New York Central Railroad strike, the question of wages is not under consideration at all. It is a question of business principle—a question whether manufacturers have a right to employ what kind of labor best pleases them, or whether they must submit to the dictations of that irrational and irresponsible species, known as walking delegates, sometimes, by courtesy, classed as workingmen. In reality the question never has come up for discussion among men of sufficient intelligence to distinguish between what is obviously right and what is just as clearly wrong. It is the indisputable right of everyone to employ any workman who is willing to work for him, no matter whether he be member of a labor union or not, and it is time that labor union enthusiasts clearly understood this.

Under the present circumstances the action of the brick manufacturers, while it must unfortunately bring suffering to many more or less intimately connected with the building trades, is entirely justifiable. It will give labor unions an opportunity to find out that sympathetic strikes can be made to work both ways, and that the gentle, persuasive measures of their own making can be used very effectively by manufacturers, their erstwhile victims.

MECHANICAL MINE VENTILATION.

In reviewing recent improvements in the mechanical engineering of coal mines before the British Institution of Mechanical Engineers, Mr. Emerson Bainbridge recently pointed out that the elements of danger, waste and inconvenience in furnace ventilation for mines have caused an almost general adoption of mechanical ventilators.

The considerations to be aimed at in selecting a mechanical ventilator are as follows: First cost of fan, engine and foundation, future cost of maintenance, economy of fuel and stores, useful effect of fan. The fans now chiefly used in England are the Guibal fan, Walker's improved Guibal fan, Cockson's, Schiele's, Capell's, Waddell's, and Lupton's fans. The Guibal fan is that most largely adopted, and is so well known that it needs no description. In Walker's improved Guibal fan the chief variation in the style is the increased strength, designed with the view of obtaining the same results with a small diameter of fan; and the air, instead of being admitted as in the Guibal fan, on one side only, is admitted on both sides. The Guibal movable shutter is replaced by an anti-vibrating shutter, which is very effective in its action. The tendency recently has been to adopt fast-running fans, which, however, are most suitable where limited quantities of air are required. Four years ago Mr. Bainbridge adopted this principle at the Woodthorpe Colliery, near Sheffield, by applying an 8-foot Cockson fan, driven direct without gear by one of Willans and Robinson's direct-acting engines, which runs very quietly at a speed of 280 revolutions per minute. At this speed the fan gives about 58,000 cubic feet of air per minute, with 3 inches water gauge. The engine since it was started has run about 500 million revolutions, and has cost a very small amount for repairs. The actual economy in the useful effect of a fan depends upon the cost of fuel; but bearing in mind that the useful effect is found to vary from about 15 per cent. to 70 per cent., the matter is of importance; and in the ordinary carrying on of a colliery the quantity of fuel used in driving a fan engine, which practically never stops working, may be said to be one-fourth of the entire fuel used. A simple contrivance in connection with ventilating machines has been adopted by Mr. Bainbridge at the Nunnery Colliery. A new engine-house which is now being completed will be ventilated by taking a pipe from the roof, and passing it into the fan chamber; the air leaving the house will pass up through two ventilators placed in the roof, and thence to the fan.

The break of a 46-inch water main in Philadelphia on the 25th inst. caused considerable damage to several houses along the line.

SLATE PRODUCTION IN THE UNITED STATES.

According to the slate census bulletin, just issued from the Division of Mines and Mining, under the charge of Dr. David T. Day, the total value of all slate produced in the United States in 1889 is $3,444,863. Of this amount $2,775,271 is the value of 828,990 squares of roofing slate, and $669,592 is the value of slate for all other purposes besides roofing. As compared with the statements of the Tenth Census report of 1880 on stone, the roofing slate product of 1889 is nearly twice as great in number of squares and in value. The total value of all slate produced in 1889 is more than twice as great as that considered in the Tenth Census. According to "Mineral Resources of the United States, 1888," the total number of squares of roofing slate produced in that year is 662,400, valued at $2,053,440.

Twelve States at present produce slate. A line drawn on the map from Piscataquis County, Me., to Polk County, Ga., and approximately following the coast outline, passes through all the important slate producing localities. According to amount and value of product, the most important States are, in the order named. Pennsylvania, Vermont, Maine, New York, Maryland and Virginia. In the remaining six States productive operations are of limited extent, and in the case of Arkansas, California and Utah of very recent date. The 12 States referred to do not include all those in which merchantable slate is known to exist, since discoveries promising good results for the future have been made in a number of other States, among which may be specially mentioned Tennessee, where operations of production are beginning.

The Bangor region, which is entirely within Northampton County, Pa., is the most important. This region includes quarries at Bangor, East Bangor, and Mount Bethel, Pa. The character of the slate produced at Mount Bethel is similar to that of the Northampton Hard Vein region. Included in the Lehigh region, besides Lehigh County, Pa., are a few quarries in Berks and Carbon Counties, and a small number in Northampton County, on the opposite side of the Lehigh River.

The Pen Argyle region embraces quarries at Pen Argyl and Wind Gap.

The Northampton Hard Vein region is specially distinguished on account of the extreme hardness of the slate, as compared with that produced in other regions of the State. This region includes the following localities: Chapman's Quarries, Belfast, Edelman, Seemsville, and Treichlers, all in Northampton County.

Five of the nine quarries included in the Peach Bottom region are in Hartford County, Md., the remaining four being in York County, Pa.

The Vermont and New York region includes an extensive slate formation occupying a part of the old Champlain Valley lying between the western base of the Green Mountains of Vermont, and the southern trend of the Adirondacks, in New York. The area in which slate is actually produced at present is confined to a narrow strip in Washington County, N. Y., and a somewhat wider one lying next to it in Rutland County, Vt. It extends from Castleton, Vt., on the north, to Salem, N. Y., on the south, a distance of 35 or 40 miles, and has a maximum width of six miles, but the average is not more than a mile and a half. With the exception of red slate, the production of which is at present limited to Washington County, N. Y., the general character of the slate in Vermont and New York is the same. It happens, however, that red slate is produced only in Washington County, N.Y., this being the only locality in the country producing this variety of slate.

The slate quarrymen of the country, and to a considerable extent the firms operating the quarries, are either Welsh or of Welsh descent, many of them having learned the methods of quarrying slate in the celebrated quarries of Wales. The quarries are operated on an average of about 220 days in the year. The idle days are the result of rainy weather and holidays. The first day of every month is regarded as a holiday by the Welsh quarrymen, and no work is ever done by them on Saturday afternoons.

The average wages for the entire country paid to foremen or overseers is $2 48 per day; for quarrymen and millmen, $1.56; for mechanics, $1.64; for laborers, $1.27, and for boys, $0.76. The highest wages are paid in California, while those paid in the most important regions naturally approximate more closely the figures above given as the averages. The following figures represent the average daily wages paid in Pennsylvania. Foremen, $2.25; quarrymen, $1.88; mechanics, $1.54; laborers, $1.40, and boys, $0.73. In the Vermont and New York region foremen receive an average of $2.65; quarrymen and millmen, $1.77; mechanics, $1.97; laborers, $1.51, and boys, $0.89. The statistics were gathered by Dr. William C. Day, special agent in charge of stone.

A BIG CALIFORNIAN FLUME.

According to the *United States Miller* a flume of exceptional dimensions has just been completed for supplying water to the city of San Diego, Cal., and also for irrigation purposes. The whole flume, 45 miles in length, has been constructed on a uniform grade of .75 feet per mile, the water being carried over 315 trestles of varying heights and through many tunnels and numerous cuts. No fills have been allowed, as with embankments there is always a risk of landslips, trestles being used in every case where these would have been necessary. The whole length is lined with redwood, which is said to be everlasting. The water is drawn from an artificial lake of 900 acres formed by the Cuyamaca dam, which is 720 feet long and 35 feet high. From here it is led along a natural flume to a diverting dam, where another lake is formed. This dam is 400 feet long by 35 feet high, and from this point the flume proper begins. Some of the longest trestles are: The Sweetwater Pass, 1,264 feet long and 81 feet high; Sweetwater Pass, No. 2, 720 feet long and 25 feet high; Sycamore Creek, 720 feet long and 35 feet high; Connor Creek, 688 feet long and 34 feet high; Knob Creek, 600 feet long and 55 feet high; Cut off, 640 feet long and 48 feet high; Los Coches, 1,664 feet long and 70 feet high; Sand Creek, 600 feet long and 58 feet high: South Fork, 420 feet long and 86 feet high; Quail Canon, 560 feet long and 68 feet high; Monte Tunnel, 438 feet long and 60 feet high; Chocolate, 450 feet long and 63 feet high; and over 300 smaller ones. The most important tunnels are: Lankersheim, 1,900 feet in length; Los Coches, 313 feet; El Monte, 290 feet; Cape Horn, 700 feet; South Fork, 200 feet; Anderton, 270 feet; and Sand Creek, 430 feet. These are through solid rock of granite or slate 6 feet square, cemented and arched overhead, supports being placed wherever the rock is soft or has any indications of falling. The flume is 6 feet wide and 4 feet deep, and its capacity when flowing full is said to be 65,000,000 gallons daily.

PERSONAL.

Dr. John S. Billings, Surgeon U. S. A., arrived from Europe on the steamship Majestic on August 27, and has gone to his home in Washington, D. C.

City Engineer Voigt, of Detroit, Mich., took leave of that office on the 20th inst. Mr. Ludden, his successor, has entered upon his duties. Mr. Voigt has made no business arrangements for the future.

Major George W. McNulty has accepted the position of Engineer of Construction on the Broadway Cable Road, of New York City, whose plant has been designed by A. D. Whitton, Chief Engineer of the Philadelphia Traction Company. Mr. Whitton also designed the North and West Side Cable systems of Chicago.

OBITUARY.

Orlando W. Atkinson, of the firm of Johnson & Co., iron founders, at Burlington, N. J., died on the 25th inst.

Walter Howe, a member of the Aqueduct Commission of New York City, was drowned while bathing at Newport, R. I., on the 22d inst.

Col. Victor E. Piolett died at his home in Wysox, Bradford Co., Penn., August 26, aged seventy-eight. He had held many positions of trust. He was Superintendent of the North Branch Canal and Superintendent of Construction of the Philadelphia and New York Railroad from 1867 to 1872.

ENGINEERING SOCIETIES.

THE fall meeting of the New England Water-Works Association will consist of an excursion of members, with ladies, to the White Mountains, in accordance with the programme which appears below.

PROGRAMME.

Saturday, September 13.—Leave Boston, Eastern Railroad station, 9.30 A. M., special cars; lunch at Wolfeboro Junction; arrive at Crawford's 3.25 P. M.; Crawford House.

Sunday, September 14.—At Crawford House. During the stay ride up Mount Willard.

Monday, September 15.—Leave the Crawford House 9.15 A. M. for the Profile House; arrive at 10.30 A. M.; carriage ride to the Flume in the afternoon.

Tuesday, September 16.—Leave the Profile House 9.20 A. M.; stage to North Woodstock, through cars to Boston, arrive at 5.00 P. M. stopping 50 minutes for dinner at Plymouth at the Pemigewassett House.

Any members of the party desiring to take a trip to Mount Washington can do so on Monday and join the party at the Profile House during the afternoon. Tickets to the Summit and return $3 each. Tickets $22 25, including railroad fare, Boston to Crawford's and Profile, stage Profile House to North Woodstock, rail to Boston; carriage ride up Mount Willard, Profile House to the Flume and return, lunch at Wolfeboro Junction, dinner at the Pemigewassett House; board from Saturday P. M. until Monday morning at the Crawford House, from Monday morning until Tuesday morning at the Profile House and services of the conductor. All the details of the excursion will be under the management of Messrs. Raymond & Whitcomb, 296 Washington Street, Boston, Mass., and all tickets must be obtained of them by members of the association on or before September 10. The return tickets will be good until October 1, 1890. Members who do not desire to purchase the round trip tickets can have rooms reserved for them at the Crawford and Profile Houses on application to Messrs. Raymond & Whitcomb. In such cases the hotel rate will be $3 per day. Should a withdrawal be necessitated, after the ticket has been paid for, the money will be refunded.

Further information may be obtained from Albert F. Noyes, West Newton, Mass.; R. C. P. Coggeshall, Secretary, New Bedford, Mass.; Dexter Brackett, 221 Federal Street, Boston, Mass.

THE fifth annual excursion of the Boston Society of Civil Engineers will occur on September 13–16, 1890, and will consist of a trip of members and friends, with ladies, to the White Mountains. The programme outlined is the same as that given above, sent out by the New England Water-Works Association, which will participate in the excursion.

HOUSE AT WABAN, MASS.—H. LANGFORD WARREN, ARCHITECT, BOSTON, MASS.

CREOSOTING OF WOOD.

THE practice of the Eastern Railway Company, of France, in creosoting sleepers is described in a recent issue of *Revue Generale des Chemins de Fer*. Sleepers as delivered are stacked and seasoned in the open air. They are then adzed and bored by a special machine, loaded on trucks, and run into a drying oven, where they remain 24 hours or more. After drying at a temperature of about 176° Fahr., they are run into a metal cylinder 6 feet 3 inches in diameter and 36 feet long, which is hermetically closed. The air is then exhausted, and a partial vacuum is maintained for about half an hour. Communication is then opened with reservoirs of dead oil, which is allowed to flow in at a temperature of 176° Fahr., under pressure. When the oil ceases to flow under moderate pressure, it is forced in by a pump up to a pressure of 83 pounds per square inch, and this pressure is maintained for an hour or an hour and a quarter. Communication with the oil reservoirs is then opened again, and the excess of oil not absorbed by the timber flows back into the reservoir. The cylinders hold 168 sleepers each. The quantity of oil absorbed is measured by determining the difference in volume of the oil before and after operation. The wood used is principally oak and beech. The oak sleepers absorb from 2.4 to 2.7 quarts per cubic foot; beech sleepers from 8.7 to 10 quarts per cubic foot. The whole operation takes about four hours. This method of treatment has been practiced by the company since 1865, with, it is stated, very good results. After fifteen years of service the sleepers taken out have been 15 per cent. for creosoted oak and 50 per cent. for creosoted beech.

COMPETITION FOR PEDESTAL DESIGN FOR THE ROBERT E. LEE STATUE.

THE committee in charge of the Annual Competition for the Clark Medals submits to the draughtsmen of the United States the following problem:

It is required to design for the equestrian statue of Gen. Robert E. Lee, recently erected at Richmond, Va., a pedestal which shall be unlike the one upon which the statue is now set. The design shall comprise the pedestal and the approaches and surroundings of the monument, and no limitation as to the cost or material or dimensions of the pedestal and its accessories are imposed by the committee.

The site of the monument for the purposes of this competition shall be immediately outside of the entrance to a public park, and at the end of a broad boulevard, on each side of which are tall and elegant buildings, apartment houses, hotels, etc.

Drawings shall be rendered on two sheets, one containing such ground plans, elevations and sections as may be required to illustrate fully the intention of the designer, and the other a perspective drawn to any scale and rendered in any manner desired by the individual competitors. The size of the sheets shall be 16x23 inches, and they are not to be rolled for the purposes of shipment.

Drawings will be received until, and not later than noon of the first day of November at the office of the Chairman of the Committee, room 1600, Auditorium Tower, Chicago.

An excellent illustration of the statue for which the pedestal is to be designed can be found in the supplement to *Harper's Weekly* of March 29, 1890.

D. Adler, Chairman.
Henry Ives Cobb,
N. Clifford Ricker,
Lorado Taft,
Samuel A. Treat,
Committee.

WORK was begun recently on the new viaduct from the heights at One Hundred and Fifty-fifth Street and St. Nicholas Avenue to Seventh Avenue at Macomb's Dam Bridge, New York. The viaduct will be of iron, and it will be 1,500 feet long. The roadway will be 60 feet wide with footways on each side. It will cost $600,000.

THE SHEFFIELD, ENGLAND, WATER-WORKS.

According to a paper on the Sheffield, England, water-works, recently presented to the British Institution of Mechanical Engineers, by Edward M. Eaton, Chief Engineer of the works, the town is supplied with water by gravitation from the elevated moorlands lying to the west and northwest, the gathering grounds forming part of the western slope of the backbone of England. The rainfall has been continuously gauged for the last fifty-four years, and averages rather more than 40 inches in depth per annum. Of this it has been ascertained from actual experience that during a period of three consecutive dry years nearly 20 inches can be collected, stored, and distributed. The system of reservoirs may be divided into the high-level and the low-level, the distinction having reference, not to absolute height above the sea, but to the means available for conveying the water from the storage reservoirs into the various surface reservoirs near the town.

The high-level reservoirs are situated at Redmires, about six miles in a direct line from the center of the town. They consist of three reservoirs—the Upper, Middle and Lower Redmires—with the Oaken Clough dam and catch-water. They receive the flow from 2,108 acres of drainage area, and have a total storage capacity of 670,000,000 gallons, the gathering ground comprising the upper part of the valley of the river Rivelin. The water from the high-level reservoirs is conveyed down a water course, open for the greater part of its length, but covered in at the lower end, into the Hadfield or Crookes service reservoir having a capacity of more than 21,000,000 gallons, whence the supply is taken for the higher parts of the town.

The low-level system comprises two reservoirs upon the River Rivelin, and four reservoirs in the adjoining valley of the river Loxley, these being the Strines, Dale Dike, Agden and Damflask Reservoirs. There is also upon the river Rivelin a small reservoir called the depositing pond. The total capacity of the low-level system of storage reservoirs is more than 3,000 million gallons. The water collected in Strines, Dale Dike and Agden Reservoirs is conveyed through a tunnel, passing under the high ridge which divides the Loxley from the Rivelin watershed; and uniting at the depositing pond with the water from the Rivelin Reservoirs, passes through a conduit and tunnel to the service reservoirs at Crookesmoor, lying immediately west of the town. In the valley of the river Ewden, lying immediately north of the Loxley Valley, the corporation of Sheffield has power to construct two other reservoirs,—namely, the Broomhead and Moorhall Reservoirs, for receiving the flow from a drainage area of 6,496 acres; but these works have not yet been commenced.

The total drainage area of the works is 15,703 acres. The total available water during three consecutive dry years is 19,460,000 gallons per day, of which an average of 9,113,472 gallons per day has to be sent down the streams as compensation water, leaving 10,346,528 gallons per day for the supply of the town and district. It will thus be seen that nearly one-half of the available supply of water has to be sent down the rivers for the benefit of the millowners and other riparian proprietors.

After leaving the storage reservoirs and being received into service reservoirs at Crookesmoor, the water is distributed throughout the town and district of supply by means of main pipes from 24 inches to 5 inches in diameter, laid in zones. The service pipes are mainly 4 inches in diameter, 3-inch pipes being laid in short streets and courts. The total length of the distributing pipes is nearly 300 miles. The total daily quantity of water distributed is about 6½ million gallons, of which exactly one-third is for trade and manufacturing purposes, or for supplies in bulk to local authorities distributing water themselves. When water was first supplied to Sheffield under constant pressure in 1869, the daily consumption was 40 gallons per head of the population supplied, of which only about 2¾ gallons per head was for trade purposes. Now, and for many years past, the quantity consumed without restriction or limitation, for all purposes other than meter supplies, has averaged not more than about 13 gallons per head per day; this happy result is due to the rigorous rejection, so far as practicable, of fittings and apparatus of an inferior character, combined with unceasing vigilance in suppressing all unnecessary waste of water.

At each of the surface reservoirs a self-recording gauge is fixed for the purpose of measuring the water supplied to the town. These recorders have been in use since 1878, and the result of their working has been to disclose several facts relating to the supply of water, of a character very interesting to all engaged in the practical management of water-works. So far as Sheffield is concerned, the least draught upon the reservoirs is between 3 and 4 o'clock in the morning, the maximum draught being between 11 and 12 noon; while the fact of the stoppage of work for dinner between 12 and 1 o'clock is strikingly manifested. In proportioning pipes for town supply, although the average daily flow through the pipes may be taken at 100, yet provision must be made for passing 50 per cent. in excess of this quantity.

The water supplied to Sheffield may be taken as a fair type of the excessively soft upland waters supplied to many of the large towns in the north of England. The hardness varies at different periods of the year, rarely falling below two degrees of Dr. Clarke's scale, and seldom exceeding three degrees. The water pressure in different parts of the town varies between 150 feet and 250 feet, or up to 300 feet head. In some spots, however, the pressure rises to 400 feet, but this is considered a dangerous pressure, and with it lead pipes last a very short time Sheffield water is used for power purposes, the motors being coupled direct to the mains, and the exhaust is measured to ascertain the consumption.

THE RADFORD, VA., WATER-WORKS.

Concerning the water supply of Radford, Va., the Radford *Enterprise* gives the following particulars:

> After a careful investigation of all the springs and streams in the vicinity and after analyses had been made of three different sources of supply by Professor Henry Leffman, Analytical Chemist of Philadelphia, it was decided to adopt Connelly's branch as the source. The analysis of Dr. Leffman shows that the waters of this stream are of high organic purity and that it is admirably adapted for use in steam boilers and for general manufacturing purposes.
>
> The pumping station has been located upon this stream, at a point where several springs of undoubted purity can be utilized as well as the waters of the stream.
>
> A subsiding reservoir, with a capacity of 1,000,000 gallons is now nearly completed in the meadow adjoining the stream and engine and boiler house. Full detail arrangements have been made so that the stream, during freshets, will pass the subsiding reservoir without entering it.
>
> The springs referred to will be conducted to this subsiding reservoir, and a supply of water which shall be always clear is fully anticipated.
>
> A substantial and ornamental engine and boiler house of ample proportions is being erected on the bank of the subsiding reservoir. This house is adapted to the convenient accommodation of two 1,000,000 gallon engines and three boilers, each of full capacity to alone operate either engine at its full capacity.
>
> A pump well and inlet chamber, with screens, blow-out and other appliances, have been provided.
>
> The pumping machinery at first to be introduced will consist of a million gallon, compound, duplex, direct acting, condensing pumping engine with duplicate boiler capacity, made after specifications by the hydraulic engineer by the Holly Manufacturing Company, of Lockport, N Y.
>
> The pumping main and the principal distribution main will be 12 inches in diameter, and the general system of distribution pipes will be of ample size, and the whole work will be proportioned for a fire pressure 125 pounds per square inch.
>
> On the top of a commanding ridge between the pumping station and the principal portion of the town, a stand-pipe will be erected which will be 25 feet in diameter and 50 feet high, with an ornamental roof some 30 feet in height. The foot of the stand-pipe will be about 200 feet above the level of the water in the stream.
>
> It is intended to ultimately use this stand-pipe for the supply of dwellings, etc., upon the higher levels of the city and to supplement it by a large reservoir to supply the lower levels when the consumption of water demands it.
>
> The whole Radford water-works have been proportioned to provide an ample fire and domestic service and the engineer has not been limited in any expenditure which he has recommended.
>
> With legitimate economy in the use of water, Connelly's branch will supply the ordinary wants of 10,000 persons and will afford them full fire protection. The works have been so proportioned that two good fire streams can be obtained from each fire hydrant without the intervention of a fire engine.
>
> The works were designed and are being executed by Mr. Howard Murphy, civil and hydraulic engineer, of Philadelphia, who engaged Mr. T. Roney Williamson, architect, of Philadelphia, to furnish him with the ornamental work on the engine house and stand-pipe.

The St. Clair River Tunnel between Port Huron, Mich., and Larnia, Ont., was practically completed on August 25. It is probably the greatest river tunnel in the world, being 11 feet longer than the Brooklyn Bridge.

PARIS PAVEMENTS.

According to the *Zeitschrift für Transportwesen*, there will be more attention paid to the granite and macadam pavements in Paris during the coming year than has been the case for some time. Property holders in the suburbs have complained that more than a just amount of the appropriations for streets is spent in laying wooden and asphalt pavements in the heart of the city. The authorities have accordingly resolved to repair or renew all the outlying streets.

The chief improvement in the granite pavements is the concrete bed that is now used as a foundation for the blocks wherever the traffic is of great volume. The new pavements are prepared in the following manner: The old blocks and the underlying sand are removed, and the ground then brought to the proper grade and heavily rolled. On this surface a concrete layer of about 8 inches is placed, and the whole covered with 3 to 3 5 inches of sand. On this sand are laid the rectangular blocks at right angles to the center of the street. Between the rails of the tramways and for 1.5 feet on either side the joints are filled with cement. The entire upper surface is then covered with sand, sprinkled with water and rammed by hand. More sand is now scattered over the surface, and after two or three days the street is opened to traffic. Several layers of sand are scattered over the pavement during the first few weeks of its use.

When broad streets are being repaired in this manner it is usual to close but one side of the street at a time, thus allowing a limited traffic to be carried on. The pavements are not popular on account of their noise, and will be restricted to the suburbs.

Macadam pavement is restricted to streets where few vehicles pass and to drives in the public parks, such as the Bois du Bologne. In repairing such roads of late years it has been customary in some places to mix old asphalt fragments with the broken stone. The results, as regards wearing qualities, show little improvement over the unmixed stone. The great advantage of the process lies in the fact that such a pavement keeps remarkably clean during dry weather and does not become so muddy as the true macadam style during rainy seasons. In the middle of summer, however, an unpleasant odor is given out, and the surface has a dirty black color.

THE CINCINNATI MANUAL TRAINING SCHOOL.

The Technical School, of Cincinnati, O., is a manual training school, started in 1886 by Col. W. L Robinson, one of Cincinnati's public spirited citizens. In 1888 the Commercial Club of that city, recognizing the value of the movement, came to his aid, and now there exists a well-equipped institution with complete carpenter, blacksmith and machine shops.

During the past winter the third and fourth classes built a 5x12 inch slide valve engine which is now driving the shop machinery. During next winter it is proposed to build another engine, a duplicate of the above. Pupils are to make sketches by direct measurement from this engine, preparing from them a set of working drawings from which they themselves are to work in the shops. Some of the details will be made in lots of three or four, a selection to be made at the end of the year for use in the complete engine. By this method of work good practical instruction can be given in machine drawing, and a series of shop exercises developed which, in themselves, have a useful purpose.

All students, in the regular course, work two hours a day for the entire first year in the carpenter shop, the same amount of time the second year in the blacksmith shop, and the same the third year in the machine shop. Special attention is given to drawing, both free-hand and mechanical. Sketching in perspective and simple projection is encouraged. In addition to manual training, studies are followed similar to those in the best high schools, except that Latin and Greek are omitted. There is a three years' course in arithmetic, algebra, geometry, trigonometry, chemistry and physics. Daily practice is given in writing and speaking English correctly.

Last year the school had 120 pupils; this season many more are expected. The work is intended for boys between the ages of 14 and 17. There are nine teachers besides a director, Mr. J. B. Stanwood, who has special supervision of the work.

Owing to the brick boycott there has been an advance in the price of bricks from $4.95 to $7.45 per thousand.

SLAG CEMENT.

In a recent article on slag cements *Le Génie Civil* states that these cements are made by finely grinding blast furnace slag and mixing it with a suitable proportion of fat lime. The grinding has to be very fine, because as the cement is made by a simple mixture it is necessary that the surface on which the two constituents, the lime and the slag, react on each other should be as large as possible if proper chemical combination is to ensue. The density of slag cements is much less than that of Portland, weighing bulk for bulk, but from .8 to .88 times as much. In general, this cement also sets somewhat more slowly than Portland, but when hardened, has, in many cases, a greater strength, particularly at early dates after setting. In some experiments still unfinished, the following results were attained with a slag cement from the Department of Isère:

Age....	1 week.	1 month.	3 months.
Breaking load, pounds per sq. in..	473.5	568.8	678.3

These figures are higher than any attained in the tests made on Portland cements for the new Croton Aqueduct. Experiments have also been made with slag cement mortar mixed with, and allowed to harden in, sea water, and gave the following results; the mortar consisted of six parts by weight of cement to ten of sand:

Age.	Breaking Weight.		Pounds per Square Inch.		
8 days	252.0	319.9	275.1	273.0	2°5.8
28 "	375.4	327.0	327.0	248.4	341.2

The main objection to slag cement seems to be that if it is allowed to harden in dry air its strength is very materially reduced, and it is then liable to crack. In the town of Villefranche-sur-Soane (Rhône) it has been largely used for paving footpaths, some 4,800 square yards having been laid there with the most satisfactory results.

On Saturday, August 23, the remains of Captain John Ericsson were transferred, with imposing ceremonies, from the Marble Cemetery, New York, to the U. S. cruiser Baltimore, to be taken to Sweden for final interment.

THE MADISON SQUARE GARDEN.

PART I.—GENERAL DESCRIPTION AND PERSPECTIVE; FRONT AND SIDE ELEVATIONS; LONGITUDINAL AND TRANSVERSE GENERAL SECTIONS. GENERAL PLAN AND PLAN OF ROOF GARDEN.

The Madison Square Garden, just completed on the site of the old garden, adjacent to the north east corner of Madison Square, New York, occupies an area about 200x425 feet square, and will be one of the most extensive amusement buildings in this country. It is owned by a stock company, for whom it was designed, and the construction was superintended by McKim, Meade & White, architects, New York. D. H. King, of New York, is the principal construction contractor. The total estimated cost is about a million and a half dollars.

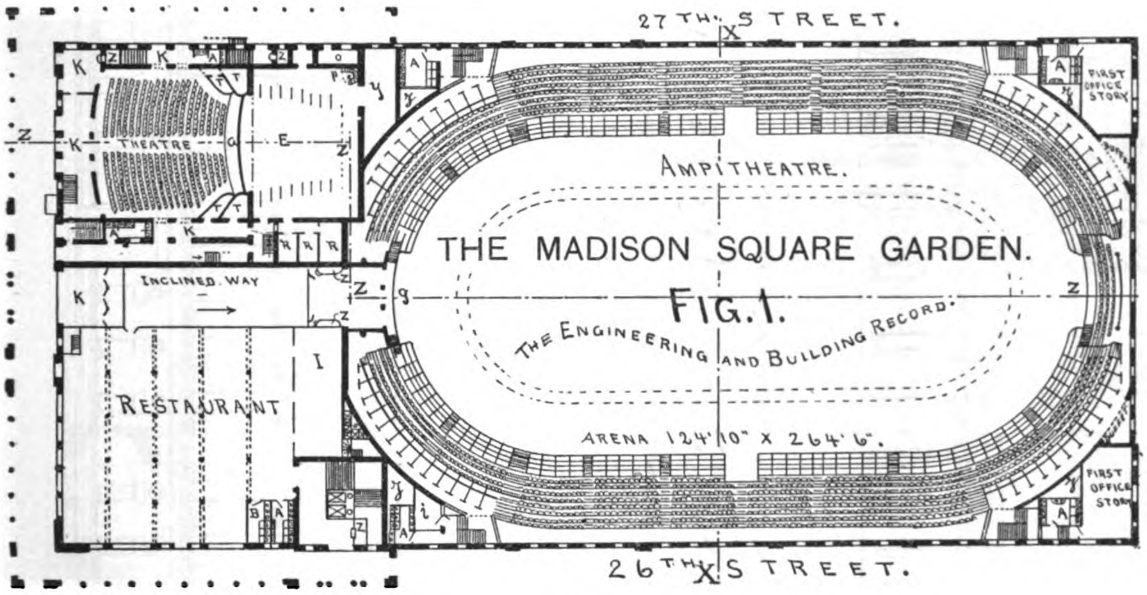
The side and curtain walls are of brick, resting on continuous massive brick foundation walls, 28 inches thick, and from 10 to 30 feet deep, which, in turn, rest on continuous Portland cement concrete footings, from 4 to 8 feet wide, and about 3 to 6 feet deep. The outside walls are 40 feet high above the level of the street to roof, and the tower is 38 feet square at the ground, and 325 feet high to the top of the figure. The partition walls are of hollow brick. The roof trusses, floor beams and columns are of wrought iron and steel, the roof of tar and gravel, and most of the doors of iron, the construction throughout being designed to be fire-proof.

At the first floor level are the amphitheater arena, the theater and a restaurant. Below the amphitheater is stabling for nearly 400 horses. Above the restaurant are concert halls and ball rooms, and the roof. Both theater and restaurant are designed for open-air gardens.

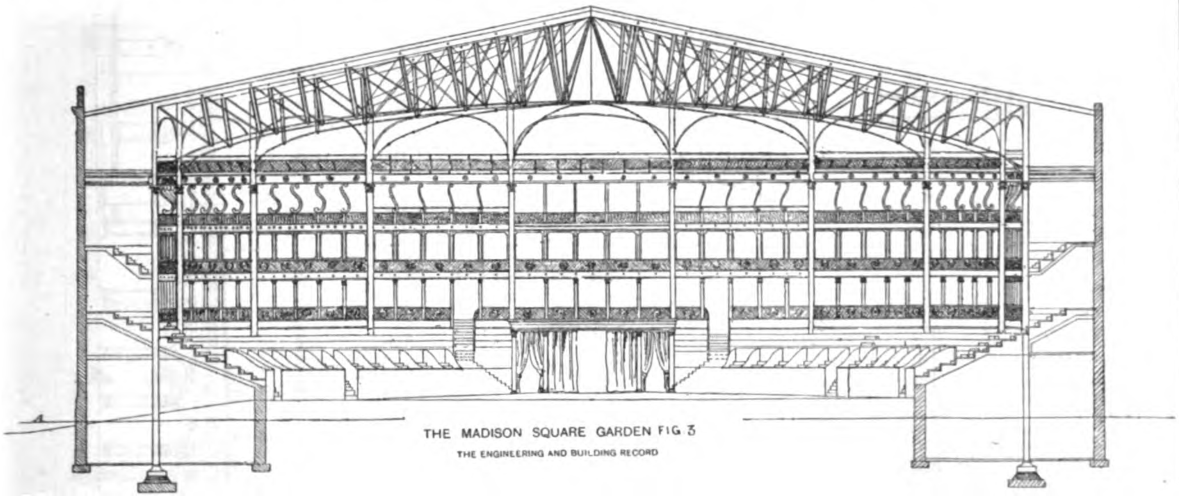
Figure 1 is the general first-floor plan. K K, etc., are lobbies; A A, etc., men's toilet rooms; B B, etc., women's toilet rooms; Z Z, ticket offices; Q, manager's office; T T, boxes; *p*, stair well; E, stage; *y*, scene room; *z*, light shaft; R R, dressing rooms; I, pantry; *j*, cloak room. Figure 2 is a section at Z Z Z Z of Fig. 1, and Fig. 3 is a section at X X of Fig. 1.

Figure 4 is an elevation from Madison Avenue, and Fig. 5 is an elevation from Twenty-sixth Street. The Twenty-seventh Street and Fourth Avenue elevations are similar to Figs. 4 and 5, respectively, except that they do not show the tower on the same arrangement of small domes. A general perspective is given on a separate page. Figure 6 shows a plan of the roof garden, and section of the roof buildings; *t*, is the pitched roof over the stage; A, men's toilet room; *u*, store room; *v*, kitchen; L, freight elevator; S S, etc., sinks; M, concert hall elevator; N, roof garden elevator; *x*, sliding skylight over theatre auditorium, movable to position indicated by dotted lines; *r*, promenade; *b*, open court of roof garden; *w*, stairs from gallery.

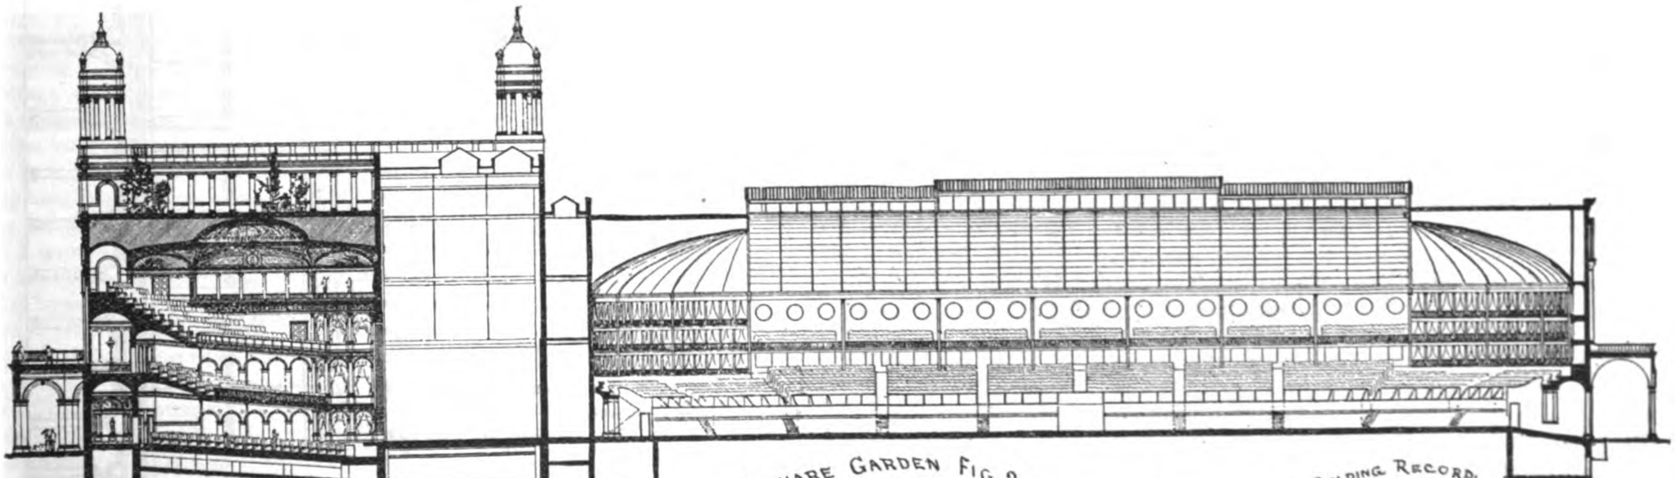
(To be continued.)



THE MADISON SQUARE GARDEN. FIG. 1. THE ENGINEERING AND BUILDING RECORD.

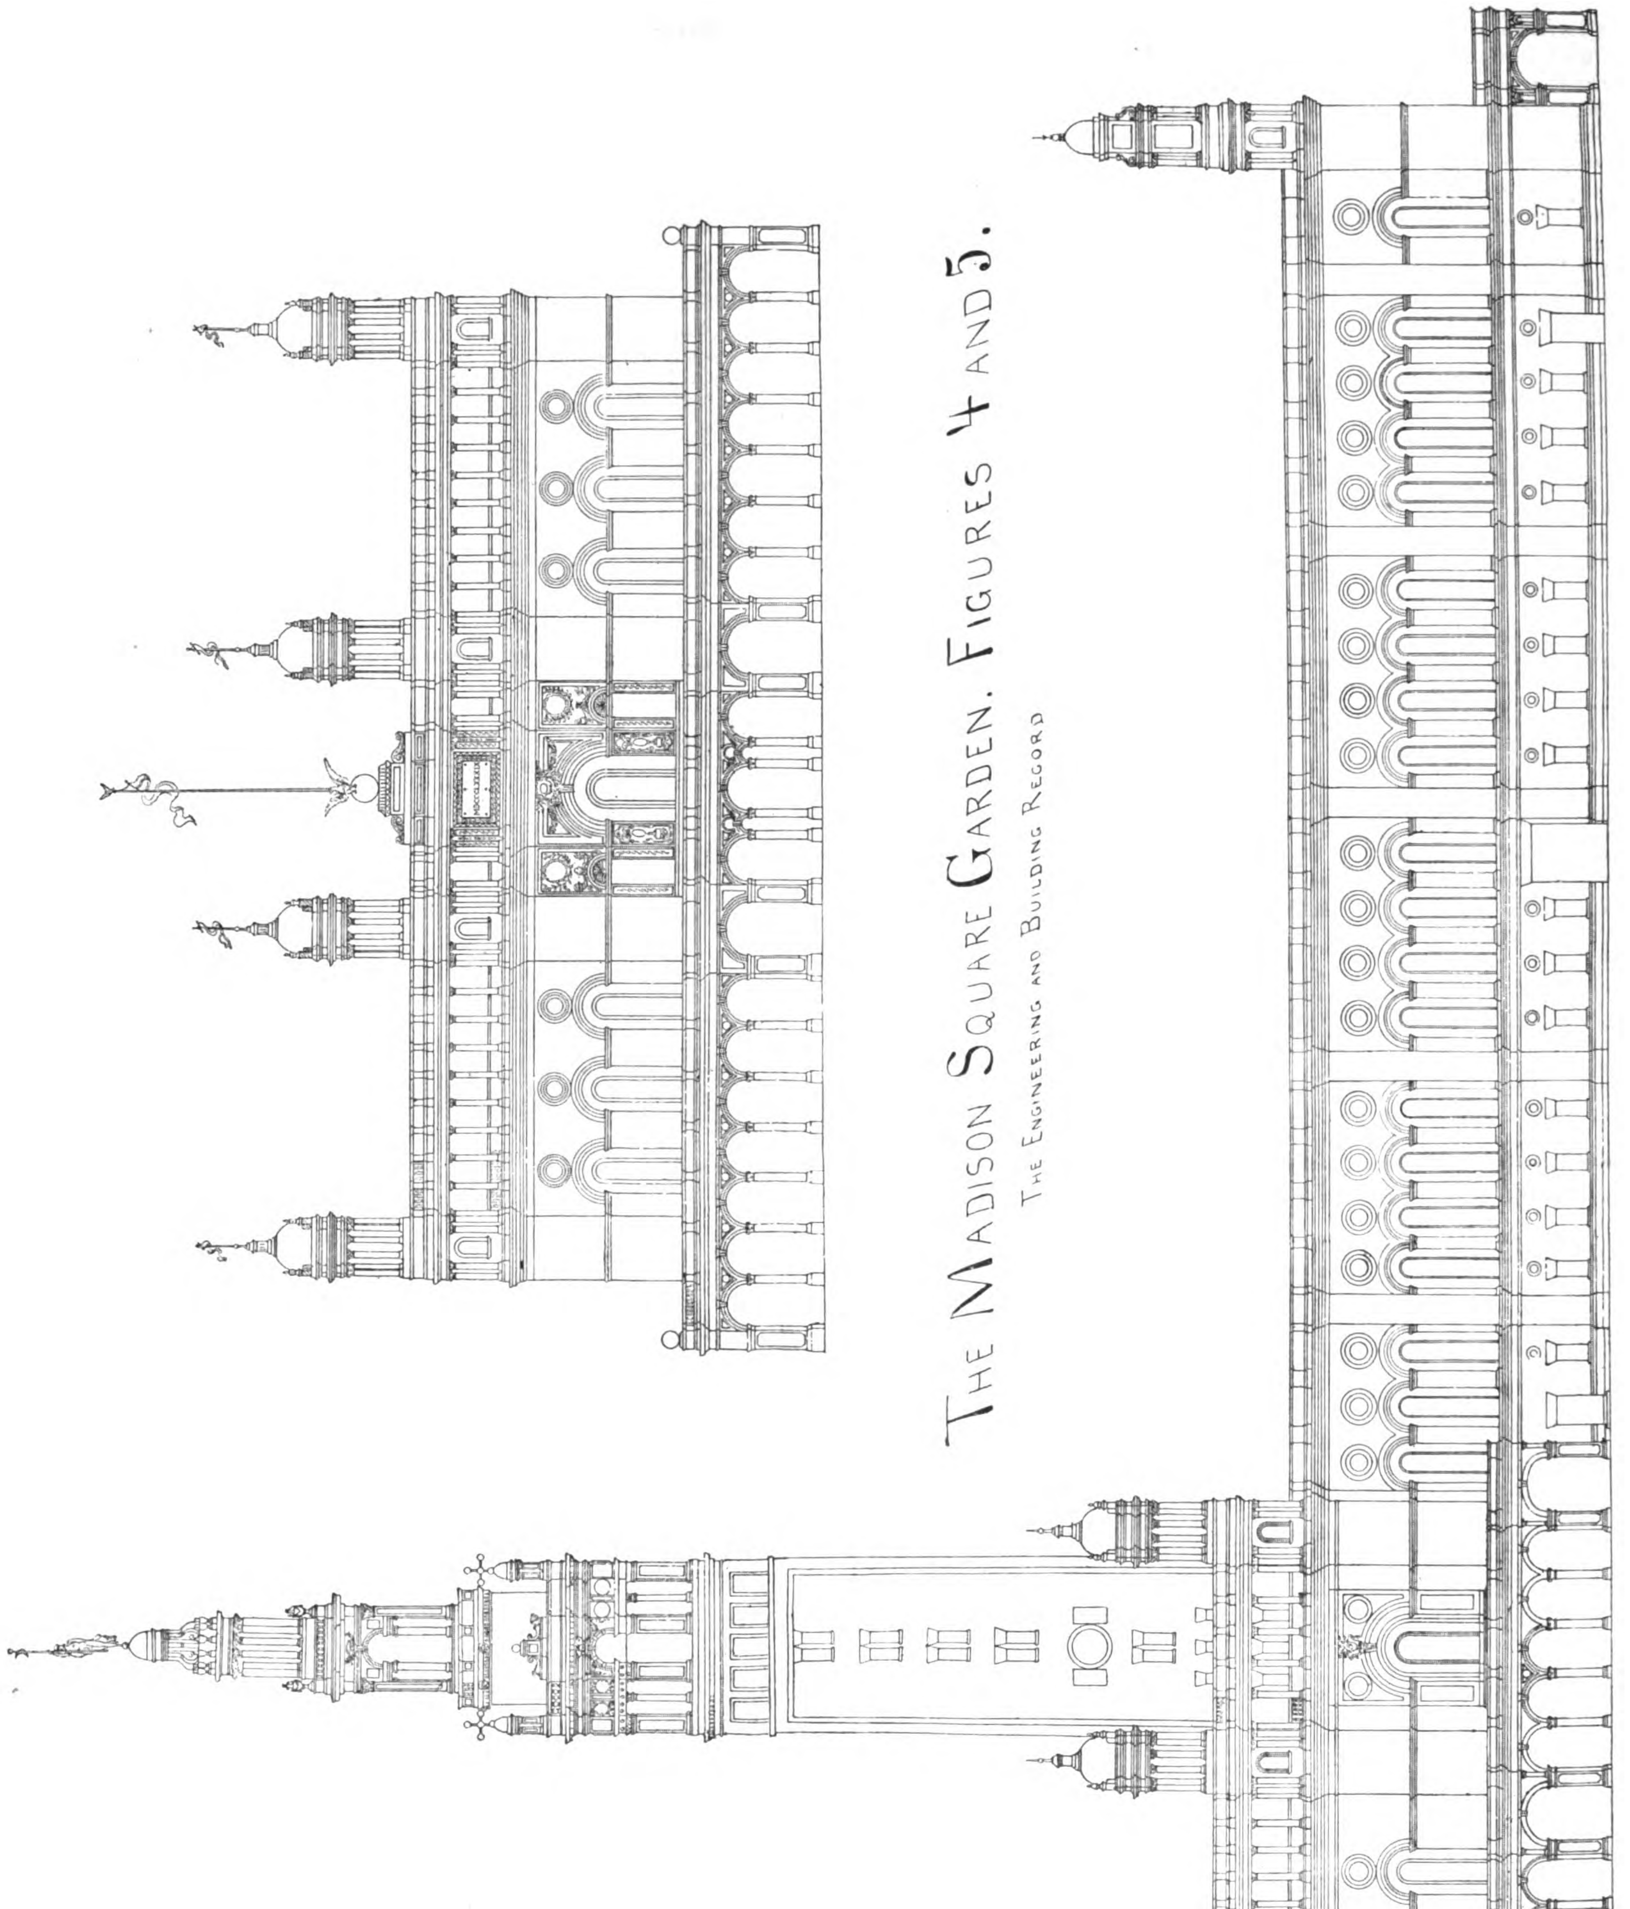


THE MADISON SQUARE GARDEN FIG 3
THE ENGINEERING AND BUILDING RECORD



THE MADISON SQUARE GARDEN FIG. 2. THE ENGINEERING AND BUILDING RECORD.

The Supreme Court of New Jersey, at its November term, will be called upon to decide whether the Plainfield Water Company has a legal existence. An application for a writ of *certiorari* has been made to Supreme Court Judge Magie by Israel Lewis, of North Plainfield, who claims in his application that the charter under which the company is operating is null and void, it having been obtained under a law which is alleged to be unconstitutional.



The Madison Square Garden. Figures 4 and 5.

The Engineering and Building Record

WIND PRESSURE.

AN article discussing records of exceptionally heavy wind pressures recently appeared in *Engineering*, in which it was contended that the very high records published from some observatories, and notably from Bidston, Liverpool, are unworthy of credence. The anemometers at this observatory have shown indications referable to a wind pressure of 80 and 90 pounds per square foot, which if actually exerted in a storm would have razed the observatory buildings to their foundations. Before 1883, several extraordinarily high anemometer records were made at Greenwich; but in that year the Astronomer Royal repudiated such high pressures, the mere substitution of a connecting chain for a wire in the mechanism of an anemograph having effected a startling reduction in the recorded pressure, although observation of light winds showed that the change was an improvement in the way of increasing the sensitiveness of the instrument. The intelligence of tornadoes that reaches us from time to time shows that, in some localities and on some occasions, wind pressures amounting to sufficient to overturn railway cars, destroy buildings, and uproot growing trees, may be met with. It is certain, however, that the more violent these storms are, the more restricted is their range. They may cut a clear strip across a town or tract of country, leaving everything bordering their path intact. No gasholder or other large and light erection would stand for an instant before such a force as a narrow tornado can exert; but seeing how local these atmospheric disturbances are, even in their native homes, engineers treat them according to the advice given in 1881 by Mr. Hawksley, when he told the British Association that no provision for withstanding the effects of whirlwinds could with propriety be introduced into calculations of the strength of structures intended to have a commercial value. Nobody will ever know what an anemometer would say respecting the pressure exerted by a typical narrow tornado in full career, because any instrument of the kind set up in the pathway of such a storm would be swept away with all its attachments.

SHRINKAGE OF FILLING ON SALT MEADOWS.

SOME interesting data in regard to the so-called "shrinkage" of filling on a salt meadow is given by Walter C. Berg, Principal Assistant Engineer of the Lehigh Valley Railroad Company, and has been furnished to this journal by Francis Collingwood, C. E.

The fill was on the east approach incline of the J. C. N. & W. Ry. to the P. R. R. Bridge at Newark, N. J. It formed, when completed a double track embankment 1,200 feet long, 14 feet above the surface of the meadow at one end and five feet at the other and having a gradient of 0.75 per cent. The surface of the meadow was about at high water level in Newark Bay and for a depth of 8 feet the soil was soft mud below which was quicksand. The track for the dump cars was first laid on a small crib of old ties and was raised from time to time as the work progressed until the proper elevation was reached.

New York City "street dirt" was at first used exclusively (shipped on cars from Jersey City from February to May, 1890), but it was afterwards covered by about 6 inches of solid earth. The material is quite compact, although considerable additional shrinkage is expected to take place when the double track is laid and put in use. The surface of the meadow on each side was not visibly disturbed by the weight of the embankment.

Up to May 28 there had been placed in the embankment, by car measurement, 20,551.2 cubic yards of "street dirt" and 1,303.9 cubic yards of earth, a total of 21,855.1 cubic yards. The total yardage by cross sections taken on that date was 15,586.7 cubic yards, showing a total shrinkage of fill of 6,268.4 cubic yards, or 28.7 per cent. of the whole amount of the material delivered. If this shrinkage be divided by the total yardage found by cross section it will give 42.1 per cent. which is the ratio in which the yardage of the completed fill must be increased in order to find the amount of material required to make it.

In a subsequent letter Mr. Berg says: "The use of the word 'shrinkage' is a misnomer in this case. * * * It is mostly compression of the peaty material underneath the fill. Relative to the proportion of the shrinkage of the street dirt proper, I am not able to say anything direct as we have had no actual observations. The percentage given under the term of 'shrinkage' should really be 'percentage showing the increase of actual volume regained over the theoretical section above the meadow level to make the fill of the kind shown under the conditions as given.' In other words, this information would give data as to how much to add to the theoretical cross sections to get at about the true volume required in making fills on salt meadow bottoms. * * * The salt meadow at this point is really very shallow and that accounts for there being no mud wave action on each side of the fill, that is, any action perceptible to the eye, as levels were not taken."

SEATLESS safety valves are said to have been brought out in England more than 30 years ago.

THE PHILADELPHIA WATER SUPPLY AND THE PHILADELPHIA AND READING R. R.

A SPECIAL injunction was granted on the 16th inst., in a bill in equity filed by the City of Philadelphia against the Schuylkill Navigation Company and the Philadelphia and Reading Railroad Company, restraining the defendants from interfering with the use of the water of the Schuylkill by the city and its inhabitants for domestic and other purposes, and from lowering the water in the pool to a point which will interfere with the use of it by the plaintiff.

The complaint stated that the agents of the defendants have, since daylight of the 16th inst., opened the locks, emptying the pools at the Flat Rock Dam, and had announced their intention of keeping the locks open until the water shall be lowered five feet below the comb of the dam. In three hours afterward the pool was lowered 18 inches, and the pumping at the Roxborough Station would have to be stopped. The section served with Schuylkill water includes Falls of Schuylkill, Manayunk, Roxborough, Germantown, Chestnut Hill and Mt. Airy.

THE ACTION OF QUICKSANDS.

THE peculiar property of quicksands in swallowing up bodies which may happen to come upon them is well known. In a paper on the subject, recently presented to the British Institution of Civil Engineers, Mr. Wilfrid Airy pointed out that articles great and small, which would be perfectly well able to float in water, are unable to do so in a quicksand, although it is of greater specific gravity than water, and are gradually drawn down. Vessels which have been stranded on quicksands by a falling tide have been unable to float off when the tide has again risen, and after being swamped have settled down deeply into the sand; and, in the descriptive accounts of such accidents, it is often stated that there appeared to be something mysterious in the way the vessels disappeared.

When a vessel or other body floats in water, it floats by virtue of the vertical components of the water-pressures around it. If, for instance, the body be a rectangular box floating with its sides vertical, then the box floats solely by reason of the water pressure on its bottom; and, if its bottom were protected in any way from the action of the water, the box would not float. This is precisely what happens in the case of a quicksand. The mingled mass of water, silt and sand which constitutes a quicksand forms a semi-fluid which is not capable of transmitting the full hydraulic pressure of the water. When, therefore, a vessel comes upon such a quicksand her bottom is partially protected from the action of the water, and she is unable for a time to float up, even after the water has risen considerably higher than the ordinary flotation level of the vessel. Sooner or later she will float up if she be not swamped.

A quicksand may be defined as a mass consisting chiefly of sand; but partially also of silt or argillaceous matter so intimately mixed with water that it forms a semi-fluid, having all the properties of a fluid, but in a minor degree. The most familiar instance of a quicksand is that of the sand on a beach, where it is kept alive and mixed up with water, soil, and organic matter by the action of land springs rising from below it; this often forms a very dangerous quicksand. But the admixture with water may be due to other causes. In general, the tendency of silty sand is to sink together and form a firm, compact body, having apparently none of the properties of a quicksand; but this very sand, when its surface is disturbed by mechanical violence, such as the force of the waves, will, to a certain depth, become a quicksand. The grains of sand become so intimately mixed up with the water that the mingled mass of sand, silt and water, becomes a semi-fluid covering the solid body of the sand to a certain depth.

It will be readily seen that the extent to which a mass of sand is capable of becoming a quicksand will depend upon the fineness of the sand, and the extent to which it is mixed with silt or argillaceous matter. If the sand be sharp and clean, no matter whether it be coarse or fine, it has very little of the nature of a quicksand; but if it be in a fine state of division, and be mixed with silt, etc., the particles will be readily held in suspension by the water, and it may form a deep quicksand. If a vessel be left upon such a quicksand by the falling tide it will sink considerably into it, and the sand will form a very complete and sufficient seal round the bottom; and on the subsequent rise of the tide the vessel will not float when the water has reached the ordinary flotation level, but a considerable time will elapse before the water can communicate sufficient of its pressure through the seal of sand to float up the vessel; and in the meantime the water will have risen considerably higher than the ordinary flotation level of the vessel.

In order to verify these conclusions, and to obtain some reliable measurement of the effect of such quicksands, Mr. Airy made experiments in the following manner: A trough was prepared containing several inches in depth of the sand to be experimented upon, with water above it; and the surface of this sand was worked up by hand so as to become "quick" to a small depth. A rectangular water-tight box, 12 inches long by 8 inches broad, was then floated in the water, and was forced down upon the sand with its sides vertical, and sunk into it to the depth of one-half inch. When released from the pressure by which it had been forced down, it remained sunk, and was held down by a great force, due mainly to the atmospheric pressure, while at the same time its bottom was protected from the action of the still greater external pressures by the seal of the sand. The time was then observed which elapsed before the external pressures were able to break through the seal of sand sufficiently to float the box.

Many experiments were made with different kinds of sand, both fine and coarse, with the general result that clean and sharp sands had few of the properties of a quicksand. But the case was different with sands which, although apparently clean, contained an admixture of clayey matter. When the box was forced down upon such sands it felt quite free as if floating, and could be moved about laterally with great ease; but it offered very great resistance to a vertical pull. The experiments all showed that there exists in fine sand, with a slight admixture of clayey matter, a capacity for becoming "quick," and holding vessels to a degree which, in combination with other causes, may act powerfully in bringing about some of the terrible and unexplained shipwrecks that so frequently occur on sand banks. If in any case it should be thought advisable to make provision for freeing ships from sand banks which they might be liable to run upon, the plan to be pursued is tolerably clear. All that is wanted is to assist the external water in breaking through the seal of the sand round the bottom, and in re-establishing the full hydraulic pressure. This could be done by forcing water with pumps through holes in the ship's bottom, and would probably soon have the desired effect.

STREET CLEANING PARTICULARS.

BEARING further on the subject of street cleaning, referred to in our issues of August 9 and 16, the following additional particulars concerning the removal of dead animals, offal, etc., from the streets of New York are interesting. The sections given are from the "New York City Consolidation Act of 1882."

SECTION 566. The Board of Health shall have full and exclusive power and authority over the removal of night soil, and in the removal of dead animals, offal, night soil, blood, bones, tainted or impure meats, and other refuse matter from said city. It is hereby charged with the duty of causing the removal of the same daily, or as often as may be necessary, and of keeping the said city clean from all matter or nuisance of a similar kind.

SEC. 567. The Board of Health is authorized to make contracts with any responsible person or persons for the removal of said offal, dead animals, night soil and other refuse matter from the city of New York, and to require and receive security in such form and amount as the said Board may approve, for the faithful performance by the person or persons aforesaid, to whom such contracts may by the said Board be, in its discretion, awarded, of all and every of the provisions of such contracts on his or their part.

SEC. 741. It shall be lawful for the Commissioner of Street Cleaning to cause to be dumped, or authorize to be dumped, snow and ice from the ends, or near the ends, of any piers, into the waters of the East and North or Hudson Rivers. But no dead animals, carrion, street sweepings, garbage, or any putrid, offensive, decaying, or refuse vegetable or animal matter shall be deposited in violation of sections 749 and 750.

SEC. 750. It shall not be lawful for any person or persons to sail, navigate or move, or to aid, direct or assist in sailing, navigating or moving, or to be employed upon or to accompany any boat or vessel containing any such animals or material as is named in the preceding section, through or upon the waters of that part of New York Bay, known as the Narrows, and lying between Forts Wadsworth and Hamilton, or any part of said bay south of said Narrows, with the intent or for the purpose of throwing or casting such animal or material, or any portion thereof, into the ocean or sea, or in any portion of the waters mentioned in the preceding section, without a permit, in writing, first obtained therefor from the inspector appointed or to be appointed under chapter 604 of the laws of 1875, and the amendments thereof, who shall have the power of granting such permits from time to time as he shall deem proper, and which shall not be inconsistent with the last preceding section, and having such regard to the course and condition of the then existing winds and tides as in his judgment shall best tend to prevent the subsequent return or deposit of any such contents of said boat or vessel within the waters of this State, if cast upon the waters beyond the jurisdiction thereof.

SEC. 752. It shall not be lawful for any person or persons to sail, navigate, or move, or to aid, direct, or assist in sailing, navigating, or moving, or to be employed upon or to accompany any boat or vessel engaged in the transportation of any dead animal, carrion, offal, or any putrid, offensive refuse, decaying or decayed vegetable or animal matter, or any garbage or sweepings taken from the streets of any city, upon the waters referred to in the last section but one, unless the same be propelled or moved by steam power; and it shall not be lawful for any steam vessel to tow or carry any of the articles mentioned in this section unless its name be plainly painted on each side.

SEC. 753. Any person offending against the provisions of sections 750 and 752 shall be deemed guilty of a misdemeanor, and liable to imprisonment for a term of not less than six months and to a fine of not less than $500, in the discretion of the court, for each and every offense, and may be arrested by the authorities of either of the counties of New York, Kings, Queens, Westchester, or Richmond. The courts in said counties respectively shall have power and jurisdiction to try said offenders, whether the offense be committed within their respective counties or not. Out of any moneys received for fines, such sum or sums shall be allowed and paid for the expenses and disbursements attending the arrest, as the court or magistrate may deem reasonable or proper.

We have also received the appended tables, giving data, for Brooklyn, N. Y., and Boston, Mass.:

BROOKLYN, N. Y

1. What is the population? A. 852,000.

2. How many houses, stores and dwellings? A. Number of stores and dwellings, 101,683; buildings other than dwellings, 7,951; total, 109,634.

3. How often are ashes removed? A. Once a week.

4. How often is garbage removed? A. Tri-weekly during May, June, July, August, September and October; semi-weekly during November, December, January, February, March and April

5. How many miles of paved streets? A. 366.911 miles.

6. With what are they paved? A. Belgian, cobble, granite and asphalt. Granite blocks, 55,303 miles; Belgian blocks, 22,410 miles; concrete asphalt, 8,822 miles; cobbles, 280,378.

7. How often are they cleaned? A. Where most traffic, nightly; others, three times a week.

8. What is the average width of main streets? A. main avenues, 70 feet; main streets, 60 feet.

9. Are your streets underdrained? A. Sewers.

10. How many sewer catch basins? A. 5,500 (estimated).

11. How often are they cleaned? A. Twice a year (average).

12, What provision for removal of dead animals from the streets A. Removed by contractor.

13. Is the above work done by contract or by day's work? A. By contract for term of five years.

14 What is the annual cost of cleaning the streets? A. $340,000 (estimated).

15. Removing ashes? A. $140,000.

16. Removing garbage? A. $95,000.

17. Cleaning catch basins? A. $16,000 (estimated).

18. Removal of dead animals? A. $800.

19. For the supervision of all above work? A $32 000.

20 What is the final disposition of the street dirt? A. Dumped at sea, in part, and part in low lots.

21. Ashes? A. Dumped at sea, in part, and part in low lots.

22. Garbage? A. By boat to sea.

23. Dead animals? A. Removed to rendering establishment.

24. Are streets swept by machinery, or hand labor? A. Both.

25. What kind of hand brooms are used? A. Bass brooms.

BOSTON, MASS.

1. What is the population? A. 450,000.

2. How many houses and stores? A. 3,214. Dwellings? A. 49,716. Apartment houses and hotels? A. 445.

3. How often are ashes removed? A. Once a week from dwellings; stores, twice a week; markets and hotels, daily.

4. How often is garbage removed? A. Dwelling houses, three times a week, in summer usually twice a week; hotels and restaurants, daily.

5. How many miles of paved streets? A. 404 miles.

6. With what are they paved? A. Blocks 26, asphalt 27, cobbles 8,. macadam 172, gravel 159

7. How often are they cleaned? A. Principal streets, daily; others, two and three times a week; the gutters to the macadam streets in outlying districts are cleaned once in two months.

8. What the average width of main streets? A. 40 feet.

9 Are your streets underdrained? A. Yes.

10. How many sewer catch basins? A. 6,000.

11. How often are they cleaned? A. From 1 to 12 times a year, as often as necessary after heavy rains.

12. What provision for removal of dead animals from the streets? A. By a rendering company at no expense to city.

13. What is the annual cost of cleaning the streets? A. $150,000.

14. Removing ashes? A. $200,000.

15. Removing garbage? A. $130,000.

16. Cleaning catch basins? A. $25,000.

17. Removal of dead animals? A. No expense to city.

18. What is the final disposition of the street dirt? A. Used for filling vacant lots, wharf property and sent to sea.

19. Ashes? A. Same as street dirt.

20. Garbage? A. Sold to farmers from adjoining towns

21. Dead animals? A. To the rendering company.

22. Are streets swept by machinery or hand labor? A. Both

23. What kind of hand brooms are used? A. Made of birch brush. The machines used are made by the Abbot-Downing Company, of Concord, N. H.

THE St. Louis Master Plumbers' Association vigorously protest the report that they contemplated withdrawing from the National Association. In a recently issued circular they say: "We want it distinctly understood that there are no secessionists in our association. * * * The St. Louis Master Plumbers' Association occupies the same relation to the National Association that the State of Missouri occupies to the General Government. We are a part and parcel of the National Association."

IT is said that the famous Kinzua viaduct, on the N. Y., L. E. & W. R. R., will be replaced by a heavier structure. The viaduct for years has been one of the remarkable bridges of the world.

COLD WATER WITHOUT ICE.

THE following method of obtaining a constant supply of cool water at all times is described by the *Railroad and Engineering Journal*, as being in general use in Hanover, York County, Pa.

The town, says the *Journal*, is closely built up and without any system of drainage, so that the water from the wells is unfit to drink. Some years ago these reasons led to the introduction into the town of a supply of very excellent water from a large spring about three miles distant. This water is brought through iron pipes, and when it reaches the consumer in summer is warm, while the water in the wells is cool. For this reason many of the inhabitants drink the well water, and, as a consequence, typhoid fever is a prevalent disease in that community. In order to obtain pure cool water, not impregnated with lime, some of the inhabitants of the place have adopted a plan which is so simple and gives such excellent results that it is worthy of general adoption wherever there is a water supply other than wells or springs. The plan is as follows: A cylindrical galvanized sheet iron tank, 12 inches in diameter and 4 feet or 5 feet long, is placed in the bottom of a well. This tank is then connected by a galvanized iron pipe with the water supply pipes, and another pipe is carried from the tank to the surface of the ground, or to any convenient point for drawing water, and has a cock at the upper end. The tank is consequently always filled with water from the water supply, and being in the bottom of the well, the water is cooled off and acquires the temperature of the well; so that that which is drawn from the tank is as cool as well water, and is without any of the impurities with which the latter is contaminated. The water drawn from the tank in one of the wells in the place named had a temperature of 56 degrees when the thermometer in the atmosphere above stood at 76 degrees.

This method gives an abundant supply of cool water during the whole summer, and can be adopted in all cities, towns or in the country. If a well is available it can be used; if not, by simply digging a hole in the ground, deep enough so as not to be affected by the surface temperature, and burying the tank, it will answer equally well. This hole might be dug in a cellar or outside the building. If the water has any impurities in suspension, such as mud, the tank should be made accessible, so that it can be cleaned occasionally.

TAPPING THE ERIE CANAL.

THE boatmen on the Erie Canal, at Lockport, N. Y., are complaining vigorously of the practice of tapping the canal at that point and at several other places. The interests involved are on the one hand the commerce of the Erie Canal, and on the other certain big manufacturing concerns which supply virtually the vitality to the Lock City. These factories are said to borrow their power from the Erie Canal.

Scarcely a year has passed since this tapping of State water began that boat owners have not complained of its serious interference with canal navigation. The great volume of water rushing into the tunnels created a sort of whirlpool and boats once drawn into the vortex could not be released until the gates in the tunnels were shut down. This year the complaints are renewed with added energy. Boatmen seem universally to agree that the trouble is worse than ever before. They are not satisfied with claiming that the situation is serious but they assert that it is positively dangerous. The chief cause for complaint seems to be a new tunnel which taps the canal above the locks and supplies the power for a "pulp" manufactory, as it is called by the boatmen.

THE PENNSYLVANIA RAILROAD COMPANY'S WATER-WORKS AT HARRISON, N. J.

THE extensive water plant on which the Pennsylvania Railroad Company has been at work in Harrison, N. J., for the purpose of securing for railroad uses a water supply for the Hudson County section of the road is completed, and will soon be ready for use. A system of wells sunk just north of the Illingworth Steel Works, three miles of water mains alongside the railway tracks, a large reservoir at Marion, and boilers and pumps at the Harrison end of the line, constitute the new water plant. The pump will bring up 400 gallons of water per minute, and it is calculated that the works can furnish the road with a quarter of a million gallons of water daily.

ADHESIVE STRENGTH OF SULPHUR, LEAD AND PORTLAND CEMENT FOR ANCHORING BOLTS.

UNDER the above head a correspondent of the Troy *Polytechnic* says that during a recent experience in constructing foundations for an elevated railway, solid rock was encountered so near the surface as to necessitate anchoring the foundation bolts in it. Some more durable and economic means of accomplishing this than by the use of sulphur or lead was desired, and Portland cement was suggested as being suitable.

A careful investigation failed to find any record showing the adhesive strength of cement in pounds per square inch, when used this way; hence it was decided to make such experimental tests as would give reasonably positive information on this point. For this purpose 14 holes were drilled in a ledge of solid limestone, 7 of them being 1⅜ inches in diameter and 7 of them 1⅝ inches in diameter, all being 3½ feet deep. Seven ¾-inch and seven 1-inch bolts were prepared, with thread and nut on one end and plain at the other end, but ragged for a length of 3½ feet from the blank end.

Four were anchored with sulphur, 4 with lead and 6 with cement mixed neat. Half of each were ¾ inch and half 1-inch bolts, and all of them were allowed to stand till the cement was two weeks old. At the expiration of this time a lever of sufficient power was rigged and all the bolts were pulled with the following results:

Sulphur—3 bolts out of four developed their full strength, 16,000 and 31,000 pounds. One 1-inch bolt failed by drawing out under 12,000 pounds.

Lead—3 bolts out of 4 developed their full strength, as above; one 1-inch bolt pulled out under 13,000 pounds.

Cement—5 of the bolts out of 6 broke without pulling out; one 1-inch bolt began to yield in the cement at 26,000 pounds, but sustained the load a few seconds before it broke.

Whilst this experiment demonstrated the superiority of cement both as to strength and ease of application, yet it did not give the strength per square inch of area. To determine this, four specimens of limestone were prepared, each 10 inches wide, 18 inches long and 12 inches thick, two of them having 1¾-inch holes, and two of them 2¾-inch holes drilled in them. Into the small holes 1-inch bolts were cemented, one of them being perfectly plain round iron, and the other having a thread cut on the portion which was imbedded in the cement. Into the 2¾-inch holes were cemented 2 inch bolts similarly treated, and the four specimens were allowed to stand 13 days before completing the experiment. At the end of this time they were put into a standard testing machine and pulled. The plain 1-inch bolt began to yield at 20,000 pounds, and the threaded one at 21,000 pounds. The 2-inch plain bolt began to yield at 34,000 pounds, and the threaded one at 32,000 pounds, the strain in all cases being very slowly applied. The pump was then run at a greater speed, and the stones holding the 2-inch bolts split at 67 pounds in the case of the smooth one, and at 50,000 pounds in the case of the threaded one.

It is thus seen that cement is more reliable, stronger and easier of application than either lead or sulphur, and that its resistance is from 400 to 500 pounds per square inch of surface exposed. The cement used throughout the experiment was an English Portland cement.

THE scheme of Commissioner Hans S. Beattie, of the New York Street-Cleaning Department, to clean some of the streets by aid of a fire engine and the flushing process, has met with the opposition of the Department of Public Works. Horace Loomis, engineer in charge of sewers, has reported to the Commissioner of Public Works that Mr. Beattie's flushing process is washing a considerable part of the dirt of the streets into the sewers and choking them up.

ANNUAL REPORT OF BUREAU OF HEALTH, PITTSBURG, 1889.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

TUNNELING THE NARROWS.

BROOKLYN, August 18, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD·

DEAR SIR: The project of tunneling the Narrows for railroad purposes, which Mr. Winans is said to favor, is not exactly a new one. It was first proposed, I believe, by one of the ablest of our engineers about ten years ago. He designed by its use and the construction of another tunnel to the main land near Hell Gate, to furnish new territory on Long Island for the storage and distribution of freight, and to give a direct and convenient all-rail route to the upper portion of New York City and to New England.

Perhaps the time is not yet ripe for the construction of this Narrows tunnel. It would, however, be unwise at any time to underestimate or exaggerate the difficulties of the problem.

The newspaper reports say that the material to be penetrated will be a soft soap-stone, easily worked and strong enough to resist the strain, and that the top of the tunnel will be 35 feet beneath the bottom of the Narrows. The character of the material predicted for in this location will, I fear, astonish some of the geologists.

The New York tower foundation of the East River bridge was excavated through sand and gravel to bed rock at a depth of about 100 feet. The recent borings for the Quaker Bridge Dam show the same or similar material to the rock bottom of a valley about 120 feet below the present level of the Hudson River. It is believed that something in the nature of a rock-bounded cañon exists below the present Hudson River valley of a depth not less than 100 feet below present tide level, and that this extends far out beyond Sandy Hook, the high grounds of the Palisades, Staten Island and the Navesink forming its western boundary. The bed of this prehistoric valley is probably rock of the earliest formation or trap. The valley has probably been filled up to present height of bottom with compacted gravel and boulders similar to the material on Long Island. It would not, therefore, be surprising if a tunnel built anywhere between 30 and 130 feet below tide level ran almost entirely in the last named material. There should, however, be nothing essentially prohibitory in this if true.

We must learn from cases of this kind and those similar to the projected Harlem Tunnels, where excessive depth is so important an item to avoid, to construct tunnels whose tops may be exposed, if necessary, above the river bottom. This is certainly not impossible, and I venture to say that when the occasion demands, will be found quite practicable.

O. F. NICHOLS.

THE NICARAGUA CANAL.

BY advices from San Francisco, information comes of the purchase by the Nicaragua Canal Construction Company of the plant of the American Contract and Dredging Company at Colon, formerly used on the works of the Panama Canal. The purchase includes seven dredges, fifteen lighters, several tugboats, and the machine shops, with all their machinery, tools and supplies of every kind complete. The entire plant is now being rapidly put in order for removal to San Juan del Norte, (Greytown,) and some of the dredges and tugs are already on their way there. Chief Engineer Menocal has arrived at San Juan del Norte to attend their coming.

These dredges are to be used in harbor dredging and in excavating the first ten miles of the canal, from its mouth to the first lock.

THE New York Board of Health Inspectors have found the water of all the public baths more or less filled with noxious particles, except at the Battery, while the bottom of nearly all contained unhealthy deposits. Dr. Edson will advise the reconstruction of the bath-houses and their removal to the ends of the different piers, where the water is purer and not liable to become stagnant.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department*. Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

ALGAE GROWTHS IN WELLS.

J. D. Thomas, President and Manager of the Paris, Tex., Water Company, writes: "We get our water supply from a system of dug wells and tunnels. We have a large open well 80 feet in diameter and 35 feet deep. In this well we have had considerable trouble and annoyance, in the spring and early summer, from an algae or vegetable growth, which gives out a disagreeable odor and taste. We have also a smaller and deeper well from which we propose to pump the water into the big well, letting it fall over the top and creating considerable agitation. Now the question is, will this agitation of the water in the big well improve it, or will it only make it worse?"

[It is doubtful whether the plan of pumping from the smaller into the larger well will make any noticeable difference, either one way or the other. Roofing over the well so as to exclude all sunlight may prevent the algae growth, as shown by experience in several somewhat similar cases. There is, according to Mr. F. F. Forbes, Superintendent of the Brookline, Mass., Water-Works, a class of plants, however, which thrive as well in complete darkness as in sunlight, but such plants are not able to make their own food, and are, hence, wholly dependent on food made by other plants. Water which contains vegetable solutions in sufficient quantity with certain organic matters might, therefore, develop an extensive growth even in total darkness.

We would be glad to hear from any of our readers concerning Mr. Thomas' inquiry.]

THOSE DANGEROUS TRUSSES.

Mr. Fredrick J. Amweg, C. E., of the firm of R. C. Ballinger & Co., Philadelphia, Pa., contractors for Herrmann's Theatre, at Brooklyn, N. Y., to which extended reference has been made in the last two issues of The Engineering and Building Record, writes:

"Relative to the communication entitled, 'Dangerous Trusses,' I beg to say that the trusses in question have never been either approved or condemned by me. We are the contractors for the building in which these trusses were supposed to be used, and Mr. J. D. Allen, of Philadelphia, is the architect, to whom we looked for all information concerning the construction of said building.

"We were not employed as the architects of this work, and therefore assumed no responsibility belonging to the present incumbent.

"We, of course, look to Mr. Allen in his capacity to make all matters satisfactory, and when done so, we are ready to go on with the work."

STEEL RAIL MAKERS IN ALABAMA.

William G. Smith, C. E., of Waterbury, Conn., writes: "Will you kindly send me the addresses of the concerns who make steel rails at Anniston and Birmingham, Ala.? I have not the facilities for finding out here. I am the engineer for a Southern electric road, and want prices from some of the Southern manufacturers."

[There are no rolling mills in Alabama which can properly be classed as steel rail mills. The Birmingham Rolling Mill Company, and the Alabama Rolling Mill Company, of Birmingham, the only works which could be put under that head, turn out only small T rails and tram rails. Possibly these would answer our correspondent's requirements.]

The horse-power transmitted by hemp ropes can be found by multiplying the square of their circumference in inches by their speed in feet per minute, and dividing by 4,000. For cotton ropes 25 per cent. should be added to the result.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

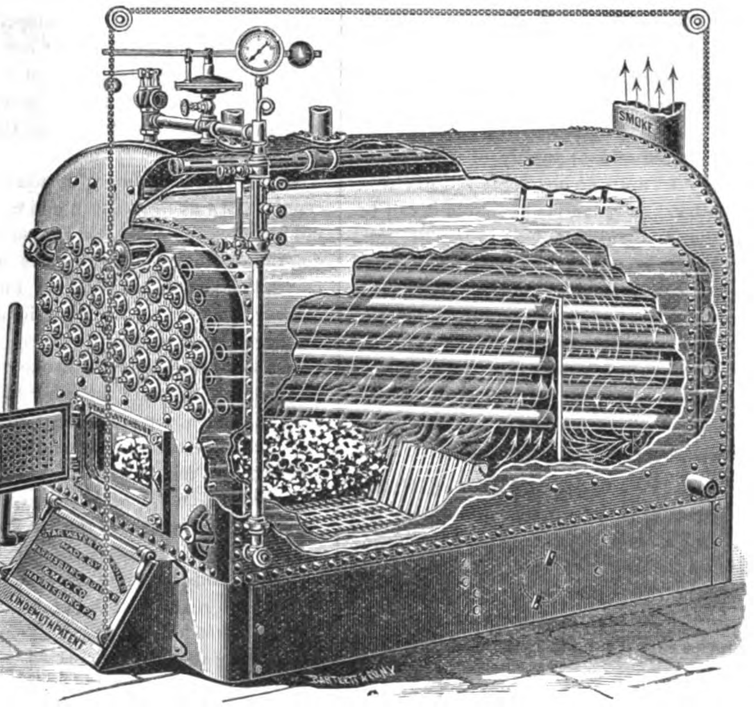
APPORTIONMENT OF COSTS FOR STEAM.

Latting & Bailey, plumbers, of Memphis, Tenn., write: "Please decide the following question: A and B have two 50 horse-power boilers coupled together. A's boiler has a six horse power engine to run and 1,500 square feet of radiating surface to heat; B's boiler has a large elevator pump to run, also a boiler feed pump and heats 2,800 square feet of surface. A's boiler has only two and three-quarter hours to run out of the twenty-four, say three hours. B's boiler is to run twenty-four hours. Please determine the percentage of fuel each party should pay for."

[The percentage of fuel to be paid for by each in this case depends altogether upon the amount of steam used by each, and this cannot be determined from the meager particulars given. Just how much steam the six horse-power engine and the elevator and feed pumps consume ought to be determined by measurements by a competent consulting engineer.

The matter should not be left to guesswork, which, in such instances, frequently goes very wide of the mark.

As regards the radiator consumption, it may be pointed out that a radiator will condense from ⅙ to ⅜ of a pound of steam per square foot of surface per hour, varying with the nature of the surface and the kind and position of the pipes.



THE STAR WATER TUBE BOILER.

With low-pressure steam, ⅓ of a pound of steam per square foot of surface per hour is not too great an estimate for the man who has to sell the steam. Accordingly, the 1,500 square feet of radiating surface supplied by A's boiler would condense about 500 pounds of steam into water in an hour, and the 2,800 square feet supplied by B's boiler would condense about 933 pounds per hour. Allowing 9 pounds of steam as the evaporative power of one pound of coal, A's boiler would use, for the radiator supply alone, about 55½ pounds of coal per hour, and B's boiler about 103 pounds per hour.]

AN IRISH CHANNEL TUNNEL.

A proposal is being entertained of having a tunnel between Ireland and Scotland, and for this three routes have been suggested—the first from Donaghadee to Portpatrick, the second from Cushendall to Mull of Cantyre, and the third from Whitehead to Portpatrick. Of these, says *Industries*, the last seems the most reasonable; but even it would require very careful consideration, for the Irish Channel is much more difficult to tunnel than the English Channel, the depth of the water in some cases exceeding 900 feet, so that the tunnel would require to be 1,000 feet below the surface of the water at mid-channel. Besides, the rock is hard and very different, as regards facility of working, from the Dover chalk.

Novelties.

Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply indorsement.

THE STAR BOILER.

The annexed cut shows the new Star water-tube boiler just brought out by the Harrisburg Boiler and Manufacturing Company, of Harrisburg, Pa.

It is designed to heat all classes of large buildings requiring 1,000 square feet of radiating surface or more, and is adapted to both steam and hot water heating. It is also claimed to recommend itself for power purposes. H. H. Lindemuth is the inventor.

The boiler is listed in 16 sizes, of which Nos. 1, 2, 3, 4, 6, 8, 10 and 12 are stock sizes, while the remaining sizes will be built to order. The capacities range from 1,000 square feet of radiating surface to 6,000 for steam, and to 1,250 for hot water heating, and from 10 to 75 horse-power for power purposes. The best shell steel is used in the construction of the boiler, together with flanged steel heads, though iron will be used where specially desired.

The general character of the design is apparent in the illustration, and requires but little description. A special feature is found in the entire absence of brick setting, the boiler being furnished with an independent cast-iron base on which it rests. The grate is of a new shaking pattern. The boiler is surrounded by a water space which measures 2 inches at the sides, and 3 inches at the ends. Great stress is laid by the builders on the relatively large amount of fire-box surface. The fire-box is deep and large and can be made of various lengths, for wood burning, for example, if desired. It is claimed to hold sufficient fuel to maintain a fire for a period of from 8 to 12 hours without requiring attention.

There is claimed, also, to be ample room for good combustion of the gases before they strike the tubes and enter into an upper chamber, not well shown in the cut, impinging there against the crown sheet. Instead of placing the smoke exit in the top of boiler, as was originally done, it is now placed in the rear of the boiler below the tubes.

Experiments recently conducted on the Paris, Lyons and Mediterranean Railroad, France, show that with boilers having tubes averaging 14¾ feet in length there is a total evaporation, in a given time, about 5 per cent. greater than with boilers having tubes 16½ feet long.

Flexible boiler stays are in extensive use on Indian railroads, and give good results.

DOMESTIC PLUMBING & HEATING & LIGHTING & VENTILATION ENGINEERING

PLUMBING IN TEN NEW HOUSES.

In a block of four-story houses just finished on East Seventy-fifth Street, New York City, the water supply for the upper stories of each house is pumped or rises through the 1½-inch pipe A, Fig. 1, and ball-cock B into the copper-lined wooden tank T, that is about 4 feet square. This tank is built to fit a special alcove, and is elevated conveniently for accessibility over the framework of 2 by 4-inch timber joists C C, etc. It rests directly on 2 by 4-inch sills D D D, laid across the lead lined safe E.

The pipe A has a branch R, which takes water from the bottom of the tank, and supplies the lower stories of the house through the filling pipe A. G is a stop cock for controlling the supply, and O is a check valve closing against an upward pressure and preventing the overflow of the tank from the pipe R. F is a special branch to the top floor fixtures only, whose supply is thus made separate to insure some draught from the tank and consequent change of its contents, even though the city pressure is sufficient to always keep the tank full and supply the branches from the pipe A without drawing through the branch R. H is a tell-tale to the cellar sink. I is the safe waste also discharging into the cellar sink (Fig.). M is a 1½-inch overflow pipe discharging into an adjacent slop-sink N.

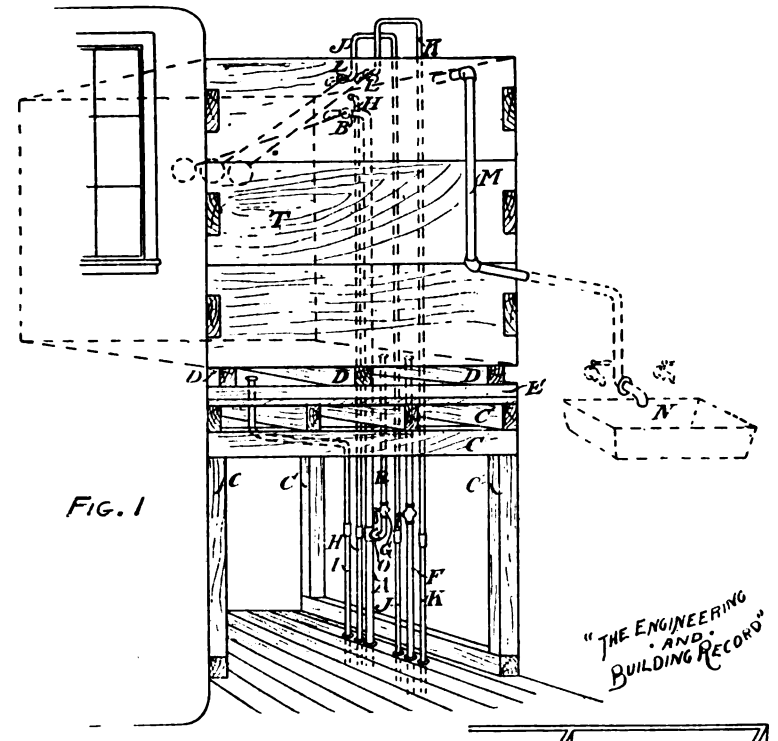


FIG. 1

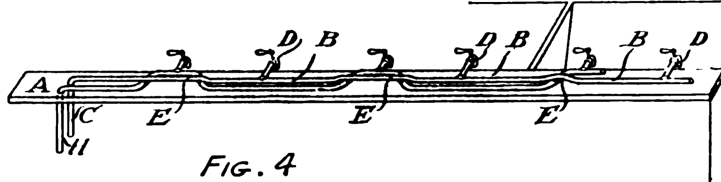

FIG. 4

PLUMBING IN A 75 ST. RESIDENCE, N. Y.

J and K are vent pipes from the kitchen boilers. Each of them terminates in a ball-cock L to prevent the escape of city water through them if the street pressure should be great enough to rise above the tank.

Figure 2 shows the double boiler arrangement in the kitchens. The outside boiler is supplied through a pipe A, with water under street pressure, and delivers hot water through a pipe B. The inside boiler is supplied through a pipe C with water under tank pressure, and delivers hot water through the pipe D. E and F are hot-water return circulation pipes, K and L are circulation pipes to the water-back, and M and N are sediment pipes for emptying the boilers. O O O are gate valves controlling the tank and hot water supplies. P and P are corresponding valves to give a symmetrical appearance to the work, but having their gates removed so that they do not obstruct the pipes or cause any danger of bursting the boilers by being accidentally left closed. The tank pipe C is connected with the street supply pipe A by the branch S, which has a check valve Q. If the tank supply fails the valve Q will open under street pressure and the inside boiler will be filled from the pipe A, but if the street pressure is cut off the valve closes downwards and prevents the escape of tank water.

The pipes are of galvanized iron, and are supported from the ceiling by special brass hangers G G, etc., which, as shown in the detail, are made in two pieces and bolted together. The upper part H is drilled and countersunk to receive the 3-inch wood screw I that can pierce the ceiling J at any point without defacing it, and is driven into a cleat K, between two floor joists L, or directly into the joists if it comes in the proper position.

Figure 3 shows the cellar sink receiving the discharge of all drip pipes throughout the house. F F F are safe wastes, G is cold water supply, H is from the refrigerator, I is a tank tell-tale, and J is sediment pipe from the kitchen boilers. All of these pipes terminate with flap valves.

A is a pipe frame supporting the sink. B is the house sewer which is carried along the cellar wall on hooks C about 10 feet apart. Holes are drilled in the stone wall and the hooks secured in them by firmly driven wooden plugs D alongside.

Horizontal pieces of gas pipe E are leaded into the wall and alternate with the hooks.

Figure 4 shows the arrangement of hot and cold water pipes H and C on the horizontal board A at the laundry tubs. The lateral branch of H is all flat on the board as are the depressed portions B B B of the pipe C. There are three summits E E E where pipe C crosses over H, and these are drained through cocks D D D. This arrangement was devised to bring all the cocks in one straight line, support both pipes on the same shelf A, and avoid making traps that could not be drained by the cocks.

This plumbing was done by Paul S. Bolger, of New York, and George H. Budlong, also of New York, was the architect of the houses.

The works of the first cable tramway in Paris, which runs from Belleville to the Place de la Republique, have been completed. The system employed is that so largely adopted in the United States.

INTERNAL GAS FITTINGS.

In a paper on internal gas fittings, read at the recent annual meeting of the North British Association of Gas Managers, Mr. R. Robertson said that architects are much to blame for existing defects in such work.

He drew attention to the circumstance that all that a gas-fitter receives from an architect, when a new house is being erected, is a specification stating the number of feet of the different sizes of pipes required. No details, or plan, or declivities are given, and the mode of laying is left entirely to the gas-fitter himself. If he has taken a job at a cheap rate, he will endeavor to use as little pipe as possible, without giving much thought about the gas supply.

Corporations and water companies having control of the water supply lay down laws and regulations as to the quality of material to be used in the water fittings inside buildings. The pipes must be of certain sizes and weights, and the cranes or taps or other fittings must be subjected to a standard pressure, and be stamped accordingly. Mr. Robertson holds that similar regulations should apply to gas-fittings, and that all gas-taps and joints should be subjected to a like examination.

Pipes used for gas-fittings are, according to Mr. Robertson, of three kinds—viz., malleable iron, composition, and block tin. The first material is the best for mills and factories where steam power is used, as from its hardness, it is not liable to be cut or break at the fastenings in consequence of the vibration caused by the working of the machinery. Of this sort of pipe, the galvanized is superior to the other, as no rust collects inside, as is sure to do in the ordinary kind; and in course of time obstruct the gas supply.

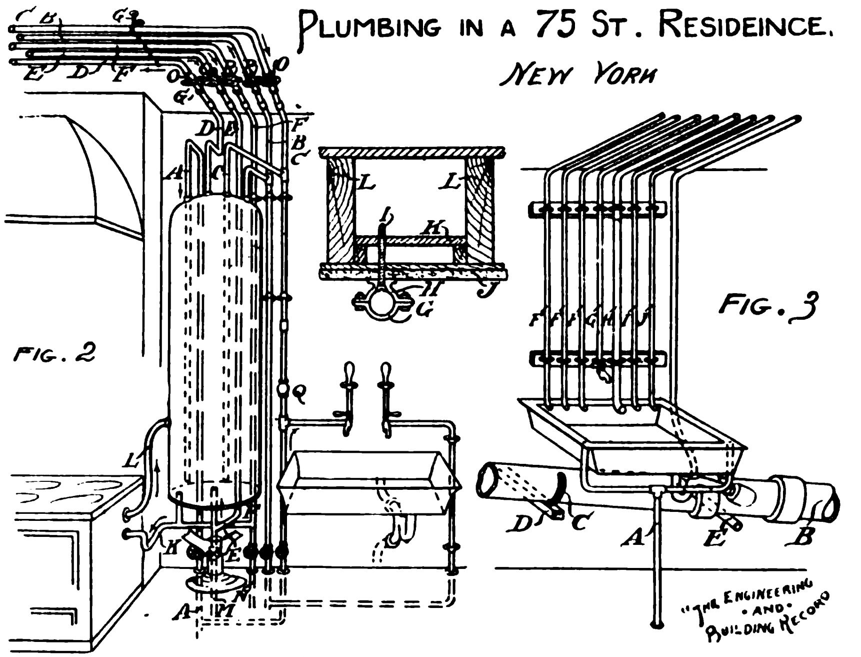

FIG. 2

FIG. 3

PLUMBING IN A 75 ST. RESIDEINCE. NEW YORK

The second kind of piping is composition, of which there are two classes—tinned and untinned. The tinned is a good article for ordinary use, and is extensively employed in country buildings. The use of the untinned kind Mr. Robertson condemns as altogether unsuitable for gas-fitting purposes. It is too easily bent, and is thus always ready to "bag;" while from the softness of its nature it gathers moisture easily, and produces that disagreeable jumping of the lights often seen.

The third class of pipes are of block tin; and these the author considers by far the best that can be used. It is hard, easily laid, rarely gathers moisture, and altogether makes a tidy piece of work. This material is often objected to as being more expensive than the others; but when weight for weight is compared, it will be found that the difference is not so great as supposed, because two yards of block tin pipe weigh nearly the same as one yard of the other. Mr. Robertson strongly recommends the use of this class of piping in preference to all others; and advises that it should be fitted up wherever possible.

One of the oldest houses in America is said to be the stone mansion on the Staats farm, about four miles below the village of Greenbush, N. Y., on the river bank. The building was erected of bluestone and brick in 1650, and at present is occupied by Lawrence and Philip Staats, and is in a splendid state of preservation.

HEATING AND VENTILATING SCHOOL-HOUSES.

(Continued from page 188.)

At the Sanborn school-house, in 1888, a more thorough work was undertaken. A minimum supply of 60,000 cubic feet per hour for each of the eight school-rooms, containing upwards of 50 scholars, was taken as a standard.

A "Clogston" heating boiler was put in, with about 3,000 linear feet of 1¼-inch steam pipe, in addition to the boiler and "direct" heating plant already there. A sheet iron air chamber, in shape resembling a triangle, was put in at each corner of the basement, each chamber drawing its air supply from two windows on two different walls of the building, each opening being covered with a coarse and strong wire grating, and provided with doors and a valve. Two upright sheet iron ducts rose from each of these corner air chambers, each duct containing a coil of 320 linear feet of 1¼-inch steam pipe. These coils, shown in Fig. 4, were each made of two sets of branch tees, one set "feed" and one "return," connected by upright and horizontal pipes and elbows, outside pipes long and inside pipes short, several "nests" of pipe, in fact one fitting inside another; the uprights from each branch tee being alternately short and long in order that the horizontal pipes might offer little obstructive area to the upward air current. For a lower room the coil was compact and the duct large in cross-section, for the vertical space was only about 7 feet, but for an upper room the coil was about 10 feet long, with the pipes fewer and further apart. The duct for an upper room ran up through the lower room and was boxed in. All ducts ran up full size, each to a point about 6 feet above its school-room floor and were open at the top.

For removing the foul air rectangular sheet-iron ducts, each 2 feet square, were used, each starting at the floor level of the room served by it in the cloak-room, and running up as straight as possible to the attic. Each duct had in it a large opening for the school-room and a small one for the cloak-room, the combined sectional area of these two openings being somewhat greater than that of the duct itself, the openings being coarsely grated, as usual. These ducts ran up in pairs from the second floor to the attic, and were there joined into one large pipe, 4 by 8 feet, ending in a rectangular Emerson cap of the same size provided with a damper. The opening from the rooms and the inlet ducts were also provided with dampers or doors, and from 45 to 70 linear feet of 1¼-inch steam pipe was placed in each outlet duct to move the air.

The Blossom Street school house, an eight-room wooden building, was fitted up in almost the same way. Both buildings have passed through one mild winter and half of another with fairly good results, the air supply being found by a few measurements to be up to the standard previously fixed and the air being pronounced good. It has been found troublesome, however, in the mild weather to keep the rooms from getting too hot.

The new building on Baltimore Street, built in 1888, has been overhauled in 1889, according to local custom, and its "indirect" steam-heating apparatus greatly increased in capacity. Its imperfect working during the previous winter was partly explained when, in taking off the louvred cupola to make room for an Emerson cap, the foul-air flues were found half covered with boards left in by careless workmen the previous summer.

As to the cost of the primary school apparatus and its maintenance, Mr. Perkins quotes from the paper on the ventilation of school-rooms heated by stoves, by Dr. J. G. Pinkham, in the Massachusetts State Board of Health Report for 1887.

"*Expense of the System.*—This includes the cost of construction and of maintenance. The cost of the improvements at the Red Rock Street School-house was $567.77; of those at the Baltimore Street School house, $554.56. At the Chase Avenue School-house $418.16 was originally expended, but subsequent changes considerably increased the cost. Quite a large part of the first cost came from the necessary tearing down and building up again. It is notoriously expensive to make changes in completed buildings. The school-house mechanic, who has had a general oversight of the work of making these improvements, estimates that if put in during the process of construction the apparatus in a two-room building would not cost more than $350; in a one-room building, $225. The change could be probably made in an old one-room building for $350. When the arrangements form part of the original plan of a school-house, they are likely to be much more satisfactory than when added afterwards.

"The cost of maintenance involves an increased outlay for janitor service and for fuel. In country districts, where the fires are cared for by voluntary service of teacher and pupils, the former item is not to be reckoned. In Lynn an allowance of 50 cents per week for each additional stove is made during the season when the fires are in operation. This amounts to something near $40 per year for each building of two rooms.

"From our experience thus far it is difficult to form an exact estimate of the increased cost of fuel. The coal and wood are supplied to the city on contract, the bins being filled up when necessary. It is certain the consumption of fuel increases somewhat in proportion to the amount of fresh air supplied. At the Chase Avenue school-house, as near as can be ascertained, from five to six tons more of coal have been burned each year since the ventilating apparatus was put in than before. It would be not far from the truth if we should reckon the increased cost of fuel for the building at $30 per year, or $15 for each room. This added to the increased outlay for janitor service makes $35 per room—surely not an extravagant sum to pay for anything so necessary to health as pure air."

(To be continued.)

ANNUAL REPORTS.

Wichita Municipal Reports; for the fiscal year ending March 31, 1890.

The pamphlet contains, besides the report of the City Engineer, H. H. Jackman, the Mayor's message, the City Clerk's report, and the reports of the treasurer, fire marshal, city physician, and street commissioner. The city engineer gives an interesting outline of the work of his department, accompanied by a number of extensive tables. Considerable time and attention has been given to the introduction of a concise system of records of work done by the department. These records include a complete record of all information relative to the sewer, with list of locations of all house connections, etc., records of curbing and guttering, giving location, cost, contractor, date built, etc.; records of permanent and wooden sidewalks, with location, costs, etc.; records of sewer estimates, paving estimates, and all other contract work; paving records showing at a glance the amount, location and kind of work done, the contractor, cost, etc.; records of cement tests, covering all well known brands of cement, and including upwards of 1,000 briquettes, copies of all plats of additions lying within the limits of the sewer district, made from the original plats on file in the office of the Recorder of Deeds; plans and specifications for all work done and under contract, filed for ready reference, together with much other information of interest of a general nature.

BRICK PAVING.

Brick paving work is described as follows in a recent issue of the *Clay Worker*:

The street is brought to the grade required, which is but little crowning—probably four inches on a street fifty feet in width. The street is then rolled with a 6-ton cast roller. Then a layer of sand is spread four inches thick, on which a layer of good common, hard brick is laid flat, but lengthwise with the street, and tamped down solidly with a heavy tamp, leaving an even surface. A 2-inch layer of sand is then spread, care being taken to fill the interstices of the flat layer of brick, after which a course of what are called in the market "black hards," are set on edge cross-wise of the street, breaking joints the same as in building; these are tamped down solidly, leaving the surface as even as possible.

Over the surface a layer of sand is spread of sufficient thickness to fill all the spaces left in laying by the common travel of the street, and the surface is again rolled several times with the cast roller. Both layers of brick are set as close as possible by hand so as to leave the smallest space only. The bricks used for the top course are very hard, but are made from common yellow clay. The bricks are burned in down draught kilns until they are vitrified. A brick that is not vitrified through as solidly as it is possible to make it when taken from the kilns is the exception. As an evidence of their character it is sufficient to say that in delivering on the streets the bricks are pitched from the wagon by hand into piles and there is seldom a broken brick. The bricks have a bright black glaze. The average cost of the pavement is estimated at $1.50 per square yard, which includes grading, curbing, etc.

TRADE PUBLICATIONS.

RADIATORS.

The Standard Radiator Company, 12-32 Porter Street, Buffalo, N. Y., is sending out an attractive little pamphlet devoted to direct and indirect hot-water and steam radiators. Illustrations, price-lists and sizes are given of various styles.

THE GORTON HOUSE-HEATING BOILERS.

A new catalogue, dated 1890-91, has been issued by the Gorton & Lidgerwood Company, 96 Liberty Street, New York. While devoted in the main to the Gorton steam and hot-water boilers, which are illustrated and described at length, it contains interesting chapters on modern methods of house heating, comparing hot air with hot water and steam systems, indirect and direct radiation, etc. Sample sets of plans and specifications also are given for direct and indirect steam systems. Illustrations of automatic water feeders and various styles of radiators occupy the concluding pages.

PAVEMENTS.

In a recently issued pamphlet the New England Paving Company, 19 Pearl Street, Boston, Mass., treats, in an interesting manner, of American bituminous rock, and asphalt pavements. A brief history is given of the material, the methods of handling are outlined and general directions offered for laying the pavements.

MAINTENANCE OF MAIN ROADS*

Manual Labor.—In purely rural portions of the main road one man will be required on each three miles, all the year round; one man on each two miles of road partly urban and partly rural; and one man on each mile and a half of road quite urban. In the neighborhood of plaster pits and collieries of course this would have to be varied. Each laborer should be supplied by the foreman with a sheet, stating the work he is to do each day, such sheet to be produced when required to be initialed by a member of the Council, by the surveyor or foreman (chief), and would take all orders and directions from the foremen.

Foremen.—The best of the existing road-men in the parishes could be engaged for this work. They should have about 12 miles of ordinary road to superintend, varying, of course, very much with the present state of the road and traffic of the future, but should live in the center of their length. Doubtless, more foremen and laborers will be required at first than later; but take a road 30 miles in length, as the work became less and the road in better condition the worst foremen and laborers could be discharged and the district of the others extended.

Each foreman should supply himself with a sheet, stating the work he is engaged upon. Such sheet to be produced when required to be initialed by a member of the Council, by the surveyor or chief foreman. The foremen should keep the time sheets of themselves and men under them; be accountable for all tools, and for the condition of their road-length; receive and check all material, entering same in their account book; take all necessary orders from the chief foreman of the district, and see the whole of the work was properly carried out, working themselves. They should have no power to discharge or engage any workmen without first reporting the matter to the chief foreman. They shall keep all tool, team and materials accounts of their divisions.

Chief Foremen.—Three chief foremen will be required for an area of about 320 miles of roads. Their duties should be to superintend the entire road management direct from the County Surveyor. They should have no power to discharge or engage any foreman without first reporting the matter to the County Surveyor, but should have full power over the day laborers. They should take all moneys from the County Surveyor for paying the foremen and roadmen fortnightly, and pay them direct, entering same in a book provided for the purpose, and get a receipt from the men on the labor sheet, to balance with the foremen's account. They should set out and direct all work for manual labor. They should check and superintend the delivery of all material under the material contracts. They should arrange and order, on check forms, all horse labor that may be required under the team labor contracts, and see the same is properly employed and entered in the road foreman's book. They should collect all accounts that might be owing by the Council for road maintenance. They should, under no pretence whatever, order any new tools, materials, or special work, unless the order is signed by the County Surveyor; in cases to avert an accident, or to save expense, alone excepted. They should walk the district under their charge, as far as practicable, and carefully take and keep notes of work required to be done. They should assist the County Surveyor in every way, in estimating for material, team, and manual labor and any other work.

Where main roads are repaired by contract under any highway or urban authority, they should walk over same, not interfering in any way with the management, but reporting any matter that should require reporting to the County Surveyor. They should initial the sheets of the foreman and day laborers of the Council, when passing at any time other than when paying the wages, collecting such sheets when paid, and returning the sheets and the duplicate pay-book of the foreman to the County Surveyor. They should work the same hours as the workmen, and do their utmost to skillfully manage and check all extravagance on the roads, filling up any spare time in doing any necessary road work. Should any foreman be temporarily laid up, the chief foreman should take his place in every way until fresh arrangements can be made. They should keep an order, tool account, material, team, and general expenditure book; also a careful diary of their day's doings, and should every year, or as often as necessary, take stock and furnish the County Surveyor with a return of stock and tools in their district.

The steam roller should be under the full direction and charge of the chief foreman, and he should pay special attention to the economical working of same.

The chief foreman and the foremen should be provided by the Council with overalls and oilskins, so that they may be on the roads during wet weather, and be able to deal at once with any matters that may only show the work necessary in such weather.

Tools.—Every foreman should be furnished with the following tools for the use of the men under him and himself:

4 shovels.
3 spades.
6 brushes.
3 wheelbarrows.
3 pickaxes.
2 hooks.
2 sledges.
4 small hammers.
4 rakes.
4 road lines.
4 scrapers.

The tools should be repaired by contract on a schedule; each blacksmith should tender every three years, or as often as might be required; and before any tools are repaired the foreman should give a written order to the smith and preserve a duplicate himself.

Team Labor and Materials.—All team labor and materials should be let by tender and contract. No material should be received unless previously invoiced, with 24 hours' notice, the total weight of each truck to be sent and the railway weight to exactly correspond, for the latter would be taken as correct. If the material be delivered by road, it should be weighed (if possible at a public weighing machine) and the exact weight of the material sent, with the carter's signature attached. All weight checks should be delivered to the road foreman at time of unloading either by the railway company, contractors for material, or the carters, on proper forms.

Accounts.—Accounts of all kinds should be sent to the County Surveyor direct, as soon as the work or contract is complete, and no account would under any circumstances be passed, unless accompanied by the necessary order for the work being carried out. Accounts for tools should be sent to the County Surveyor, at least one month before the meeting of the County Council.

County Surveyor.—He would take the direct management of all the roads, now under the various parish management, setting out all work to the chief foreman, continually drive over the whole of the main roads of the county, and superintend the carrying out, so far as possible, his own instructions; prepare estimates for material, team labor, and money payments, advertise for and receive all tenders for work, and lay same before the Highways Committee; keep all accounts, and prepare the necessary balance sheets.

Carriage Road.—The whole surface to be swept or scraped as often as required, and on no account shall the road, under any condition, be left for more than eighteen hours (Sunday, Good Friday and Christmas Day alone excepted) after rain or bad weather, without being carefully attended to. The scrapings, etc., when not wanted to repair the footpaths or for filling hollows in the roadside, or stone depots, must be carted away when dry, and on no account to be heaped and left on the roadside. The water-table at the roadside or side channels to be lined with material if soft or too low, and any clay or other matter which may prevent this being properly done shall be taken out and carted away, and the road filled and rammed with large stone. The channels shall be frequently inspected, and kept clear of all obstructions, the whole being carefully sided, and outlets cut open at least twice during the twelve months. After rain the sand-drifts shall be at once removed, and no weeds, etc., shall be allowed to grow in the side channels, so as to interrupt the free passage of the storm water. The material shall be applied to the road carefully, evenly, and smoothly, and frequently raked over, to prevent all tracking until the whole becomes one solid mass; the road, before any material shall be applied, being first swept and cleansed free of mud. Where the road is flat, care shall be taken and material allowed to raise the same to the gauge mentioned hereafter. Where the road shows soft, weak portions, the latter shall be removed, and the road made sound by means of ramming in large stones. Where the road shall require the ruts filling, care shall be taken to keep the filled-in ruts properly filled with material, so as not to allow other ruts to form at the sides; but no ruts shall be allowed to form after those already on the roads are carefully mended. Any loose stone on the road between the 1st of April and the 30th of September shall be at once picked off. If the road should be blocked with snow, so as to impede traffic, the local authority shall forthwith remove the snow, informing the County Surveyor of same, and the cost will be paid according to scale of charges appended herewith.

As far as practicable, all roads shall be formed with a fall of one-quarter inch to a foot from the center to either side.

The cross drains, gutters, culverts, and other surface water carriers shall be kept in good repair, and free from obstructions; where ditches are above the level of the road, the local authority shall see they are properly lowered and cleaned out.

During the summer, water-carts shall be employed watering through urban districts at the rate specified in the attached schedule.

All material shall be consolidated if possible by the use of a steam roller, and where same is hired for use, it shall be paid for at the rate shown on the attached schedule. Where new material is consolidated with a steam roller, it shall be applied thus: First the edges shall be cross scored from the center to the sides at an angle of 45 degrees; then the new material shall be applied, not more than two stones thick, rolled, and consolidated, the surface evenly rolled, and, if found necessary, a very slight binding material applied, carefully swept and watered; finally, rolled in, and all superfluous water and dirt swept off. The roller shall consolidate at least 1,400 square yards of new road surface in one day of ten hours.

---

* Abstract of a paper presented at the annual meeting of Municipal and Sanitary Engineers and Surveyors, Liverpool, England, June 26, 1890, by E. Purnell Hooley, Assoc. M. I. C. E., County Surveyor of Nottinghamshire.

A CONVENIENT draughtsman's, so called, triangle has lately been devised, having one right angle and the adjacent angles of 45 and 60 degrees, which gives a very obtuse angle of 165 degrees opposite the right angle in the middle of the side opposite the right angle.

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." ***Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.***

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-207.

AT a meeting of the trustees of the Masonic Home and Asylum, held at Utica, N. Y., August 27, the modified plans of architect W. H. Hume, of New York, were accepted. The plans will be on exhibition at Masonic Hall, in New York City, until September 20, the date of the opening of the bids. Bonds in the sum of $50.000 will be required for the faithful performance of the work. The grounds surrounding the building will be laid out after plans by John Y. Culyer, C. E., of Brooklyn, who will also plan the sewerage, drainage, etc.

WATER.

For Additional Water Items see Proposal Columns.

WELLESLEY, MASS.—The Water Commissioners of this place have decided to lay a new 18-inch syphon pipe from the filter well to the pump well.

MARBLEHEAD, MASS.—The Water Commissioners have received bids for digging a well to be used in connection with the system of water works recently built for this place. This well, which is to take the place of a number of small driven wells, will be 30 feet in diameter and about 24 feet deep, and water will be pumped directly from it into the stand-pipe.

BURLINGTON, COL.—A press dispatch says: "Burlington is suffering from a lack of water, and the citizens are praying the Council to take some step toward supplying the town with a system of water-works."

AMERICUS, GA.—It is stated that a reservoir, with a capacity of 88 000 gallons, will be built at the pumping station of the water-works. The Mayor can furnish additional information.

OXFORD, N. C.—The election to consider the issuance of $50,000 of bonds for the construction of water-works will be held September 8.

MILLEDGEVILLE, GA.—According to reports the Moran Springs property has been sold to parties who will establish a system of water-works, at an estimated outlay of $100,000.

SANTA ANA, CAL.—Press dispatches state that on August 19 the people of this place voted the sum of $60,000 in bonds for the purpose of establishing a system of water-works.

LANSDOWNE, PA.—Caspar Pennock, of this place, writes: "Some four years ago, I, for my own benefit, erected water-works to supply some houses of my own, and have gradually continued to supply my neighbors until we have over 90 houses at present, and have another pumping station under way. We pump from driven wells about 150 feet deep, very good water. Have obtained a charter for a water company, and about to put the plant into the water company."

MENASHA, WIS.—City Clerk P. J. Robertson writes: "There has no steps been taken yet to establish water-works here. The Garland Banking Company, of Minneapolis, Minn., is seeking to obtain a franchise to put in water-works, provided the city rents a certain number of hydrants for fire purposes."

SUMMIT LAKE, WIS.—Regarding the report that this place was to have water-works, William West writes: "There has never been anything said in this village in regard to water-works. As the village has less than 50 residents therein it is likely to be as it is for some years."

SPOKANE FALLS, WASH.—This place is to have water-works, at an estimated cost of $20,000.

WHITE SULPHUR SPRINGS, MONT.—The citizens of this place have decided to organize a company to supply the town with a system of water-works.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

WATER.

MIDDLEBURY, VT.—Village Clerk Henry L. Sheldon writes: "On August 19, the village appointed a committee of ten, A. A. Fletcher, chairman, to establish a system of water-works, by pumping the water from Otter Creek River through iron pipes, for fire, domestic and other purposes, with no reservoir or tanks. Funds to be raised by issuing 30-year village bonds. Estimated expense, $36,000, of which $6,000 was donated by a former resident. No contracts yet made."

WINCHESTER, TENN.—It is reported that G. L. Hogun & Co. have decided to establish a system of water-works at this place.

MARYSVILLE, KANS.—This place is to have a system of water-works. For particulars, address Charles F. Kolster, as above.

PORT ANGELES, WASH.—The Port Angeles Water Co., the Port Angeles Light Co. and the Port Angeles Construction Co. have been incorporated at this place. Combined they represent a capital of $750,000.

WELDON, N. C.—Reports say that a company of Northern capitalists have been formed at this place, under the name of the Great Falls Water Power Co.

COLDWATER, MICH.—The question of issuing $70,000 in bonds for water-works system was voted on at a special meeting held on August 18, the vote was carried by a majority of 184.

COLUMBIA, S. C.—The Water-Works Committee recommends the purchase of water wheels and pumps to the amount of $25,000, to increase the supply of water.

LAKE FOREST, ILL.—The projected water-works for this place will be established at once.

MT. VERNON, IND.—The question of establishing a system of water-works at this place is still being agitated.

ARKADELPHIA, ARK.—Reports say that the construction of water-works is contemplated at this place. For particulars address T. R. Tennisou, as above.

LOUISVILLE, KY.—A plant is to be established at this place by the Domestic Water Company, with a capital stock of $50,000. For particulars address P. J. Hobbs, as above.

SAN DIEGO, CAL.—Plans for the water supply system at this city will be prepared by J. D. Schuyler.

GREENVILLE, S. C.—Reports say that the American Pipe Manufacturing Company, of Philadelphia, Pa., which has a contract to construct water-works in Greenville, will organize a stock company to operate the plant.

CHURCH HILL, PA.—Reports say that the question of establishing a system of water-works is being discussed by the officials of this place.

STEELTON, PA.—A system of water-works to cost $180,000 will, it is reported, be established at this place.

EMERSON, GA.—Reports say that the people of this place have decided in favor of having a water-works system.

COMANCHE, TEX.—It is probable that immediate steps will be taken towards establishing a water-works system at this place. For particulars, address J. N. McCarthy, as above.

ELMA, WASH.—It is proposed to take steps at this place towards establishing a system of water-works.

QUANAH, TEX.—A complete system of water-works is to be established at this place by the Quanah Water, Ice and Electric Light Company. The estimated expenditure is $75,000.

BOSTON, GA.—Reports say that an artesian well is to be sunk at this place.

CHEYENNE, WYO.—The Wyoming and Nebraska Irrigation and Water Supply Company has been incorporated at this place, with a capital stock of $800,000. Water will be taken from the North Platte River and applied principally in Laramie County.

LEEDS, IOWA.—A company has been organized at this place, and a system of water-works is to be established at once. Operations will commence as soon as the preliminary affairs can be arranged.

NEW BRITAIN, CONN.—Civil Engineer Cadwell, of New Britain, has completed plans for the proposed new dam to be built at Shuttle Meadow, and submitted them to the City Council.

BUCHANAN, MICH.—A petition is in circulation at this place asking the Common Council to call a special election to decide whether to build water-works or not.

NEWMANSTOWN, PA.—The citizens of this place are, it is said, agitating the question of establishing a system of water-works.

INDEPENDENCE, KAN.—L. C. Mason, of this place, writes: "As yet there has been nothing done in the way of improvements or extensions. The works have passed into the hands of a new company. They expect to make some valuable improvements very soon, but no work done only on paper."

TORONTO, ONT.—Additional pumping facilities have been recommended by the water-works officials for the plant at this place.

MERIDEN, CONN.—It is probable that important steps will soon be taken towards increasing the water supply of this place.

WATER VALLEY, MISS.—A press dispatch of August 21 says: "Mayor Herring, by order of the Town Council, issued his proclamation this morning ordering an election to be held in this city on September 29, on the proposition to issue $10,000 of the city's bonds, to be placed on the market to raise the necessary funds for the erection of an electric light plant and the establishment of water-works in this city. It is generally supposed that the proposition will be easily carried."

BELMONT, N. Y.—The people of this place have begun to agitate the question of establishing a system of water-works.

KNOXVILLE, TENN.—Reports say that improvements are to be made to the local water-works system at that place. Gen. R. N. Hood can furnish particulars.

ORANGE, N. J.—A resolution asking the Water Committee to report at the next meeting of the Common Council as to the best means for increasing the water supply was adopted at a meeting of the Water Board held August 26.

MONTROSE, N. Y.—Reports say that a system of water-works is to be established at this place.

HUMBOLDT, IOWA.—This town voted, August 18, in favor of putting in water-works. The system will be commenced at once.

ROCHESTER, N. Y.—At a meeting of the Executive Board, held August 25, it was resolved that the Chief Engineer of the Water-Works be directed to have made the various improvements on the conduit line and repairs of gates at Rush Reservoir and Hemlock Lake, as recommended in his report on condition of the conduit, etc., presented August 18. Among the proposed improvements are renewals in the air valves, boxes, etc.; repairing the gates, resetting stone monuments, etc. Mr. Aldridge, of the Executive Board, can furnish details.

FORT SMITH, ARK.—As an extension of the system of water-works of this place, about eight or ten miles of mostly 6 inch pipe will be laid in the newly settled sections of the city, which are at present without any proper water supply.

ASHLAND, KY.—The proposed new system of water-works will be built by a company of which J. M. Gardner of this place is President. Water will be taken from the Ohio River and pumped into a reservoir having a capacity of 2,500,000 gallons.

GRIFFIN, GA.—This place is to have a system of water-works established by the Griffin Water and Light Company. W. A. Bedell can furnish particulars.

MADISON, GA.—Reports say that a proposition has been made to the local officials to construct a system of water-works.

NEW YORK CITY.—The following proposals for constructing an earth and masonry dam, Reservoir D, were opened August 27 by the Aqueduct Commissioners: M. S. Coleman, $397,262.50; Brenchand, Pennell & Company, $403,657.50; Clinton Stephens, $405,440; Smith & Brown, $407,037.50; Charles Peterson, $445,570.

For building an auxiliary earth and masonry dam, near Craft's Station, at reservoir: M. S. Coleman, $83,092.50; Brenchand, Pennell & Company, $84,602.50; Smith & Brown, $86,050; J. J. Ridgway, $96,142.50; Clinton Stephens, $113,875.

GAINESVILLE, GA.—The City Council has appointed a committee of six citizens to report as to the advisability of establishing a system of water-works. Address the Town Clerk for particulars.

SIOUX CITY, IOWA.—It is probable that about two and a half miles of water pipe will be laid in this city Alderman Powell can furnish information.

SOUTH ACTON, MASS.—This place is taking steps towards procuring a system of water-works.

EATONTON, GA.—The people of this place are agitating the water-works question. For particulars, address B. D. Lumsden, as above.

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Algona, Iowa; Pasco, Wash.; Franklinville, N. Y.; Newport, Ky.; Blue Hill, Neb.; Goakum, Tex.; Allegheny, Pa.; Austin, Tex.

THE CONTRACTING NEWS DEPARTMENT of **THE ENGINEERING AND BUILDING RECORD** is edited with a view of giving space to no item that does not indicate where professional services or supplies may be needed in the near future, the prices bid for work or supplies, and the correction of false or misleading reports in some papers, that may subject readers to needless trouble and expense in going after something that does not exist.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

MARLBORO, MASS.—Work was begun last week on the new system of sewerage, by downward intermittent filtration, according to plans furnished by the engineer, M. M. Tidd, of Boston. The contracts for building 3½ miles of the main line and also the filter beds have been awarded. The street sewers will be built by the town itself. The main line will be about five miles long, and the effluent stream will discharge into Hagar's Pond. The total cost of this system will be about $175,000, of which $60,000 will be paid by the City of Boston as a compensation for so extending the system as to prevent contamination of certain sources of the Boston water supply.

NORTHAMPTON, MASS.—The Sewer Commissioners have awarded the contract for the Hawley and Market Street sewer to A. Brazos & Sons, of Middletown, Conn., at $12,000.

JERSEY CITY, N. J.—Work on the sewer that is to be constructed by Jersey City and the North Hudson Township is to be begun next month. It will cost about $200,000.

GRAND FORKS, N. D.—City Engineer W. S. Russell writes: "Have voted to bond for $50,000 for a sewerage system, and I am directed to prepare plans. Do not think anything further will be done this season."

TROY, N. Y.—Numerous sewer extensions are to be made in this city.

AUGUSTA, ME.—The question of establishing a new sewerage sytem is being agitated by some of the citizens of this place.

OAKLAND, CAL.—T. W. Morgan, City Engineer, writes us that he has considerable sewer work which is about to be constructed.

KANSAS CITY, MO.—E. Butts, of this place, writes: "There has been no steps taken recently to establish a new sewer system. I would say that the present system has been fixed on some time ago and extensive work is now being done on what is known as the O. K. Creek Sewer, one mile of which is under construction, and another mile will be ready for bids shortly."

COLUMBUS, GA.—Council Clerk M. M. Moore writes: "The matter of issuing about $100,000 of bonds to build a system of sanitary sewers is under consideration by the City Council, but the issue will first have to be authorized by the Legislature, which meets in December, so, as yet, nothing is definitely decided upon."

SEWERS.—See our Proposal Columns for information regarding sewer construction at the following places: Key West, Fla.; New Haven, Conn.; Cleveland, O.; St. Louis, Mo.; Tiffin, O., Avondale, O.; Elizabeth, N. J.; Buffalo, N. Y.; Para, Brazil; Somerville, N. J.; Harrison, N. J.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

PROPOSALS will be asked for the building of the Eighth Street Viaduct at Cincinnati, as soon as the Board of Public Improvements decide the questions at issue.

MINERAL SPRINGS, UTAH.—The Carlton Improvement Co., of this city, will erect a bridge to Stansberry Island.

WINONA, MINN.—The Milwaukee and St. Paul Railroad will erect a new bridge across the Mississippi, opposite the city of Wabasha.

GREENSBURG, N. Y.—A new county bridge is to be erected over Sewickley Creek at Hunker Station.

HARPER FERRY, W. VA.—Charles H. Grail, Secretary of the Harper's Ferry and London Bridge Company, writes: "The Harper's Ferry and London Bridge Company was incorporated in July, and has organized and expect to build the bridge this coming winter."

EWING, N. J.—An iron bridge is to be erected at this place. For particulars address Mr. McGuire, of the Board of Freeholders, as above.

ST. JOSEPH, MO.—Chief Engineer Godley, of the K. C., is supervising plans which are being made for the construction of a new iron bridge, with stone wall abutments, over Whitehead Creek, at the railroad tracks.

GALVESTON, TEX.—The Sabine Street bridge is to be rebuilt, at an estimated cost of $5,783. Address the Mayor for particulars.

HUNTERDON COUNTY, N. J.—It is proposed to expend the sum of $8,000 in repairing bridges in this county.

EAST TEXAS, PA.—The Lehigh County Commissioners will, it is said, soon want bids for erecting a bridge over the Little Lehigh River, at this place. It is to be an iron structure, 60x16 feet.

NEBRASKA CITY, NEB.—At a special election the vote to bond the city for $100,000 for the purpose of building a bridge across the Missouri was carried.

BALTIMORE, MD.—It is proposed to erect a bridge over Druid Lake in Druid Hill Park, this city. The structure is to be 2,000 feet long. For information, address the Mayor, as above.

AUGUSTA, GA.—Reports say that the City Council has appropriated $8,000 to construct a bridge over the canal at Broad Street in West End. The Mayor can furnish information.

CHESTERTOWN, MD.—It is proposed to either repair the present bridge over the Chester or build a new structure.

BRYAN, TEX.—An iron bridge is to be placed over the Navasota River, near Chaney Crossing. Address the Town Commissioners, as above.

MIDDLESBROUGH, KY.—Reports say that it is proposed to construct a through girder iron bridge of about 70 feet span and 100 feet width across the canal on Cumberland Avenue. B. L. Lloyd, City Engineer, can furnish details.

JACKSON COUNTY, W. VA.—The County Commissioners of this county have ordered two new bridges to be built, one over Little Mill Creek and the other over Dudden's Fork. Both bridges are to be of steel.

DENISON, TEX.—This city will soon let the contract for the construction of an 1,800-foot viaduct, 20 feet wide, across the railroad at Gandy Street.

NORFOLK, VA.—The Norfolk Company has, it is stated, purchased the Ghent and De-Brees properties, will improve same and construct an iron bridge over De Brees Creek.

LATONA, WASH.—The County Commissioners have been asked to aid in the construction of a bridge across the eastern arm of Lake Union, at Latona. The estimated cost is $6,000.

SALISBURY, MD.—The Baltimore and Bay Shore Railroad Company will erect a new bridge over the Nanticoke River, at this place.

BRIDGES.—See our Proposal Columns for information regarding bridge construction at the following places: Brooklyn, N. Y.; Bastrop, Tex.; Pineville, Ore.; Big Island, Va.; Northampton, Mass.; New Gretna, N. J.

NEW DEPOTS.

SALISBURY, MD.—A new depot is to be erected at this place by the Baltimore and Bay Shore Railroad Company.

KANSAS CITY, MO.—Reports say that a Grand Central Depot is to be erected in this city, at an estimated cost of $400,000, by the Winner Investment Company.

SHELTON, CONN.—Reports say that a new depot will be erected at this place.

RAILROADS, CANALS, ETC.

TRENTON, N. J.—The Perth Amboy and Long Branch Railroad Co. has filed articles at this place for a road to connect the New Jersey Central in Middlesex County with the New York and Long Branch Railroad at the north end of the Raritan River Bridge in the same county. The connection will be 6,000 feet long. The incorporators are James N. Duberry and Henry D. Welsh, of Philadelphia, and others.

STREET-WORK AND PAVING.

CHESTER, PA.—Considerable street work is to be done at this place in September.

MONROE, N. C.—Considerable street paving is to be done at this place.

READING, PA.—A large amount of street paving is to be done in this city. See our Proposal Columns for particulars.

HARRISBURG, PA.—Considerable street paving is to be done at this place. Address M. Schaffer, of the Board of Highway Commissioners, as above.

GAS AND ELECTRIC-LIGHTING.

EARLINGTON, KY.—This place is to have an electric light plant.

MERRIMAC, MASS.—The people of this place will establish a gas plant at an early day.

SHELBINA, MO.—The sum of $5,000 has been appropriated at this place for the purpose of establishing an electric light plant.

JACKSONVILLE, ILL.—The sum of $15,000 is to be expended on improving the plant of the Jacksonville Gas Light and Coke Company at this place.

MOMENCE, ILL.—The Momence Electric Light Company has been incorporated at this place, and a plant will be established at once. Address I. C. Riker, as above.

BAY CITY, MICH.—Reports say that another electric lighting company is to be established at this place.

LIMA, O.—The Lima Electric Light and Power Company is to double the size of its plant. Particulars can be obtained by addressing S. W. Moore, the Superintendent and General Manager, as above.

OSCODA, MICH.—An electric-lighting plant is to be established at this place.

UNIONTOWN, PA.—The Uniontown Light and Heating Co. contemplates putting in a large arc dynamo.

BUCKSPORT, ME.—The electric-light plant at this place is to undergo extensive improvements. Address E. H. Gouring, of Bangor, Me., for particulars.

CAMDEN, N. J.—The Camden Lighting and Heating Company will enlarge its plant and increase the machinery. A 700 horse-power engine will be added, about 5,000 incandescent lights and 300 arcs. The work of making these additions will be commenced immediately. In addition to the above they propose extending the circuits for lighting the southern section of the city, the plans for which have been perfected. The estimated outlay is $75,000.

CRAFTON, PA.—This place is to have an electric light plant at once.

MONROE, N. C.—The question of establishing an electric light plant at this place is to be decided by the people at a special election to be held at an early day.

ANDERSON, S. C.—An electric lighting plant is to be established at this place by the Anderson Hotel Co.

WELLSVILLE, O.—The Valley Electric Light and Power Co. has been incorporated here, with a capital stock of $25,000.

HUNTINGTON, IND.—The Huntington Light and Fuel Company has been incorporated at this place with a capital stock of $250,000. John K. Price is at its head.

JAMAICA, N. Y.—The Jamaica Gas Company offers to supply gas for public lighting on the basis of a $20 per lamp per annum payment, for all night lighting, the burners to be rated to the passage of 4 feet per hour.

PHILIPSBURG, MONT.—An electric lighting plant is to be established at this place.

BREWER, ME.—An electric light plant is talked of for this place.

TULARE CITY, CAL.—An electric light plant is to be established at this place.

ELECTRIC RAILWAYS.—New electric railways will be built and improvements will be made to those already established at the following places: Duquoin, Ill.; Toledo, O.; McKeesport, Pa.; Trenton, N. J.; West Lynn, Mass.; Attleboro, Mass.; Keokuk, Ia.; Davenport, Ia.; Los Angeles, Cal.; Ogden, Utah; Dayton, O.; Akron, O.

BIDS OPENED.

NEWARK, N. J.—The following contracts have been awarded for work on Prudential Insurance Company's building: J. B. & J. M. Cornell, New York, iron work, $275,000; Geo. W. Roydhouse, Philadelphia, mason work, $269,900; Geo. Brown & Co., Newark, cut stone work, $179,850; V. J. Hedden & Sons, Newark, carpenter work, $111,000; Otis Bros & Co., New York, elevator work, $42,350; Baker, Smith & Co., New York, heating and ventilating, $33,468; J. M. Bonnell & Son, roofing and metal work, $27,350; Perth Amboy Terra Cotta Co., terra cotta work, $8,950. Contracts for minor work, amounting to about $50,000, are yet to be awarded.

WASHINGTON, D. C.—The Phœnixville Iron and Steel Company, of Phœnixville, Pa., has been awarded the contract for the iron and steel work for the Washington Loan and Trust Company's building.

PORT HURON, MICH.—The contract for excavating the approaches for the St. Clair Tunnel at Sarmi and Port Huron, has been awarded to Messrs. Nihan, Elliott and Phinn, of Bradford, Ont., at $200,000.

SAN FRANCISCO, CAL.—The contract for the iron and steel work on the Crocker Building, this city, has been awarded to the Phœnixville Iron Company, of Phœnixville, Pa. The cost of the building is $1,250,000.

SIOUX CITY, IA.—The contract for the erection of St. Joseph's Hospital was awarded to W. E. Stevens. The following bids for plumbing work in connection with same were received: A. F. Paige & Co., $2,173; Lewis Kettleson, $2897.50; W. O. Merrill, $2,417.91; Fitts & Co., $2,163; J. F. Gearen, $2,073, to whom the contract was awarded.

ALBANY, N. Y.—Superintendent Hannan opened bids August 25, that were received for dredging 18,000 cubic yards of earth, and excavating 150 cubic yards of rock from the channel of Rondout Creek. The contract was awarded to P. W Myers, of Albany, N. Y., whose bids are 15 cents per yard for the earth, and $9 for the rock.

GOVERNMENT WORK.

WASHINGTON, D. C.—The following proposals for the work specified were opened on the given dates by the Supervising Architect of the Treasury Department:

Augusta, Me.—Decorative painting, etc., first story and main stair hall of the United States Post Office and Court House at this place, opened August 22. Bidders: Peter Ackerman, Bangor, Me., $1,573; John W. Berry, Gardner, Me., $1,425 and $1,150.

Pittsburg, Pa.—Marble work, etc., for the United States court house and post office at this place. Opened August 26. Bidders: Pickel Marble & Granite Co., St. Louis, Mo., $98,900; Samuel Young, Allegheny, Pa., $109,900; if Georgia or Tennessee marble is substituted for specifications, $99,900; Sherman Flavin, Chicago, Ill., $121,400; Blue Ridge Marble Co., Cincinnati, O., if Georgia marble is substituted for specifications, $59,298; Davidson & Sons, Chicago, Ill., $129,000.

Washington, D. C.—Repairs, etc., to the heating apparatus at the United States Treasury Department. Bidders: John Lyon, Washington, D. C., $1,548; William E. Wood & Co., Baltimore, Md., $3,250.

INDUSTRIAL.

WINDSOR, ONT.—Reports say that a wagon and passenger tunnel will be built under the Black River at Port Huron, from a point in Point Huron to be determined upon, to the Canadian shore at Sarnia. The principal stockholders, it is said, will be Mayor Kenney and W. H. Anderson, of Port Huron, and Mayor White, of this city.

SALT LAKE CITY, UTAH.—A press dispatch to the Omaha *Bee*, dated August 24, says: "Plans are ready for a hotel at Mineral Springs, bordering on Carlton Beach, Great Salt Lake, together with about 50 cottages, a school-house, a mill, stock houses, servants' quarters, etc. A bathing resort will be erected on Stansberry Island, and, later, a hotel. Engineers have already made surveys. It is understood that the Union Pacific has a controlling interest in the company."

APPLETON, WIS.—An effort is on foot to form a company, with a capital of $500,000, to build a cotton factory at this place.

NEW CORPORATIONS.

SAN FRANCISCO, CAL.—The Tulare Electric Light and Power Company has been incorporated. Capital, $50,000. The incorporators are F. W. Eaton, John C. Turner and others.

RUTLAND, VT.—The Marble City Electric Light and Power Company has been incorporated. Capital, $50,000. The objects of the company is to furnish arc and incandescent lights for street and commercial use, and electric power for manufacturing purposes. The directors are A. C. Bates, J. E. Creed, E. Pierpoint and others.

PROPOSALS.

(Continued from page ii.)

PROPOSALS FOR PLUMBING, ETC.—Depot Quartermaster's Office, David's Island, N. Y. H., August 4, 1890.—Sealed proposals, in triplicate, will be received until 11 A. M., WEDNESDAY, September 3, 1890, and opened immediately thereafter, for supplying and fitting up **BATH-TUBS, WATER-CLOSETS** and **URINALS** in basement of 1889 Brick Barrack at this place. Plans, specifications, general instructions to bidders and blank forms of proposals will be furnished to bidders on application to this office. The right to reject any or all bids is reserved to the United States. Captain J. MCE. HYDE, Assistant Quartermaster, U. S. Army, Depot Quartermaster. 13

PROPOSALS FOR THE ERECTION OF Barrack. Office of the Quartermaster, U. S. Military Academy, West Point, N. Y., August 12, 1890. Sealed proposals, in triplicate, subject to the usual conditions, will be received at this office until 12 o'clock, noon, on the 1st day of September, 1890, for the erection of one **BRICK CAVALRY BARRACK** as per plans and specifications to be seen at this office. Inclose proposals in envelope marked "Proposals for Erection of Barrack," and addressed to the undersigned, CHAS. W. WILLIAMS, Captain, and A. Q. M., U. S. A. 13

IMPROVEMENT OF PHILADELPHIA HARbor. U. S. Engineer Office, 1428 Arch Street, Philadelphia, Pa., August 16, 1890.—Sealed proposals, in duplicate, will be received at this office until 11 A. M., TUESDAY, September 16, 1890, and then opened, for **DREDGING** in Philadelphia Harbor, Pa., for removal of Smith's and Windmill Islands. The attention of bidders is invited to the Acts of Congress approved February 26, 1885, and February 23, 1887, Vol. 23, page 332, and Vol. 24, page 414 Statutes at Large. For all information apply to C. W. RAYMOND, Major of Engineers, U.S. Army. 15

SEWERS, Tiffin, O.—Proposals are wanted until September 6, for the construction of certain sewers. Address Jeremiah Rex, City Clerk, as

PROPOSAL.

BRIDGE, Northampton, Mass.—Proposals are wanted until September 10, for the erection of an iron bridge over the river at Loudville. Address the Highway Committee, as above.

SEWERS, Buffalo, N. Y.—Proposals are wanted until September 8, for the construction of certain sewers. Address George E. Mann, engineer, as above.

SEWERS, New Haven, Conn.—Proposals are wanted until September 3, for the construction of certain sewers. Address A. B. Hill, City Engineer, as above.

PAVING, Reading, Pa.—Proposals are wanted until September 20, for paving numerous streets. Address City Clerk Fetter, as above.

SEWERS, Elizabeth, N. J.—Proposals are wanted until September 8, for the construction of certain sewers. Address H. J. Stratemeyer, Jr., Street Commissioner, as above.

IRON WORK, Newark, N. J.—Proposals for iron work and bluestone work on the new jail building for Essex County will be received until September 4. Address Peter Mullins, Chairman Building Committee State Bank Building.

LEVEES, Convent P. O., La.—Proposals are wanted until September 3, for the construction of seven levees. Address A. M. Cook, President of the Board of Commissioners for the Pontchartrain Levee District, as above.

PUMPING STATION, Allegheny, Pa.—Proposals are wanted until September 3, for the erection of a pumping station, Twelfth Ward. Address James Borem, Comptroller, as above.

SEAWALL, San Francisco, Cal.—Proposals are wanted until September 15, for the construction of a seawall, 1,000x200 feet. 70,000 tons of stone and 84,000 cubic yards of earth will be required, also 60,000 feet of wharf. Address the Board of Harbor Commissioners, as above.

WATER-WORKS, Blue Hill, Neb.—Proposals are wanted until September 11, for the construction of a system of water-works. Address A. A. Richardson, Consulting Engineer, as above.

COURT HOUSE, Kansas City, Mo.—Proposals are wanted until September 15, for the erection of a court house and jail at this place. Address A. Van Brunt, Architect, No. 200 West Sixth Street, as above.

SEWER, Harrison, N. J.—Proposals are wanted until September 2, for construction of pipe sewer in Fourth Street. Address John Wade, Chairman Sewers and Drainage Committee.

SEWERS, Avondale, O.—Proposals are wanted until September 8, for the construction of certain sewers. Address W. Ellwood Wynne, Corporation Clerk, as above.

SEWERS, St. Louis, Mo.—Proposals are wanted until September 5 and 12, for the construction of about 44,833 feet of sewers. Address Robert E. McMath, C. E., Sewer Commissioner, City Hall, as above.

PAVING, Brooklyn, N. Y.—Proposals are wanted until September 2, for paving numerous streets. Address John P. Adams, Commissioner of City Works, as above.

BRIDGE, Bedford City, Va.—Proposals are wanted until September 5, for the erection of a bridge over Reed Creek, near Big Island. Address B. F. Coxe, Big Island, Va.

BRIDGES, Loup City, Neb.—Proposals are wanted, no date specified, for the erection of two bridges over the Middle Loup River. Address the Sherman County Clerk, as above.

TECHNICAL INSTRUCTION.

TOO LATE FOR CLASSIFICATION.

EASTON, PA.

LAFAYETTE COLLEGE. PARDEE SCIENTIFIC DEPARTMENT. Courses in Civil, Mining, and Electrical Engineering. Chemistry, Metallurgy, Geology, Physics, Drawing. Free Course in Highway Construction. For Catalogue of the above or other Departments address the Registrar.

POSITIONS WANTED.

TOO LATE FOR CLASSIFICATION.

WANTED.—SITUATION AS ARCHITECtural draughtsman. Three years' experience. Address BENJ. JONES, 363 East Third Street, Cincinnati, O.

CIVIL ENGINEER DESIRES A PERMANENT situation with reliable water-works company or in the water department of some enterprising city; the West preferred. Good salary expected and best of references given. Address WATER-WORKS, Box 7, this office.

HEATING ENGINEER, FOR STEAM OR HOT water, expert in estimating and planning of apparatus, desires employment. Ten years' experience. Willing to travel for heating firm. Address ENERGY, Box 12, this office.

CIVIL ENGINEER, GRADUATE, DESIRES position with some engineering firm where he can make himself useful. Willing to go anywhere. Address C. E., Box 15, Nutley, N. J.

AN ENGINEER EXPERIENCED ON EARTH work and masonry, also office and general field work, would like position on sewerage or water-works. Address CIVIL ENGINEER, Box 82, this office.

A YOUNG MAN WITH SOME EXPERIENCE in draughting and calculation, wishes an opening in some branch of engineering or architecture. Salary no consideration. Address J. J. A., Box 23, this office.

Building Intelligence.

We solicit from each and every one of our readers information relating to projected buildings in their locality, and should be glad to receive newspaper clippings and other items of interest.

MISCELLANEOUS.

ADAMS, MASS.—Br parsonage; cost, $7,000; o, Church of the Seven Dolores; a, F S Newman.

ALLEGHENY, PA.—Osborne, P F W & C R R, 2-story fr dwell; cost, $11,000; o, W J Prentice; a, Alston & Heckert; b, Rose & Fisher.

ASBURY PARK, N. J.—A cottage to cost $12,000 is to be erected at this place by Rebecca Wright.

BALTIMORE, MD.—S w cor Pine and Lexington sts, 3-story br bldg; o, James Friedenwald.

S e cor Pulaski and Maryanna, br church; o, St Thomas Lutheran Church.

Maryland av near Oak st, 3-story br bldg; o, Julius A Eppley.

BOSTON, MASS.—164 Heath st, br manufactory; cost, $15,000; o, H H Reuter; a, F N Footman; b, D H Jacobs & Son.

Lyndehurst st nr Allston st, 2 fr dwells; cost, $9,000; o, a and b, Jos H Beale.

Richfield st, 3 fr dwells; cost, $9,000; o, a and b, W J Jobling.

Dudley st cor Nonquit st, br hotel; cost, $63,000; o, Frost Bros; a, J M Brown; b, M S and G N Miller.

566 Parker st, br offices and hall; cost, $16,000; o, Alice C Moulton; a, Fred Pope; b, Henry W Moulton.

Reedsdale st nr Brighton av, fr dwell; cost, $7,000; o, John D Wetherell; a, F D Fuller; b, J H McLeod.

Marginal st cor Cottage st, br church and Sailors' Home; cost, $25,000; o, Episcopal City Mission; a, W M Bacon; b, Holmes Bros.

Norfolk av nr Magazine st, br cordage works; cost, $20,000; o, Pearson Cordage Co; a, W F Clark; b, McMorrow & Gately.

Humboldt av nr Homestead st, fr dwell; cost, $11,000; o, N P Ryder; a, Eugene L Clark; b, H McLaughlin.

Austin st, br engine house; cost, $40,000; o, Fitchburg R R; a, E K Turner; b, as above.

380 Tremont st, br alteration; cost, $6,000; o, R T Paine; b, as above.

BRIDGEPORT, CONN.—Barnum av, br school house; cost, $40,000; o, City of Bridgeport; a, Longstaff & Hurd; b, H M Purdy.

CAMBRIDGE, MASS. — Cambridge st, addn to br church; cost, $12,000; o, Second Baptist Society; a, W J Paine: b, W C Ryder.

Harvard st cor Dana, fr dwell; cost, $40,000; o, O H Durrell; a, Hartwell & Richardson; b, W Filmore.

Lambert av, fr dwell; cost, $8,250; o, D W Ellis; a, J M Brown; b, C Leake.

Carlisle st, br and fr dwell: cost, $6,500; o, Wm O'Connor; a, G Fogarty; b, W H Paterson.

Lake Shore drive, stone and br residence; cost, $80,000; o, O W Potter; a, F R Schock.

Washington blvd nr Albany av, br dwell; cost, $12,000; o, S R Warner; a, Hetherington & Warner.

175 W Madison, pavilion; cost, $20,000; o, Geo Reichold; a, J E Scheller.

Ellis av, br dwells; cost, $12,000; o, L P Friested; a, G Bloedner & Co.

225 buildings costing less than $7,000 each.

CATASAUQUA, PA.—Fourth st, s and fr cottage; cost, $8,000; o, J W Fuller; a, L S Jacoby; b, Messrs Sterner & Kress.

CINCINNATI, O.—Pearl and Lawrence sts, 3-story stable; cost, $12,000; o, Cincinnati Railroad Omnibus Co.; c, Stein & Shulthoff.

McMillan st and Reading road, 1-story br power house for electric generating station; cost, $17,000; o, Cincinnati Street Railroad Co.; construction engineer, Bert L Baldwin.

Renner st and Dalton av, 4-story br furniture factory; cost, $7,000; o, DePinal & Rennekamp; a, G and A Brink.

Fulton and Nassau sts, 7 2-story br dwells; cost, $8,000; o, Sharp Bros; a, Frank Parmelee.

CINCINNATI, O.—Locust st and Ashland av, 2½-story br dwell; o, W H and H Wachtell a, W S Robinson.

Walnut and 7th sts, 4-story br bldg; cost, $80,000; o, Young Men's Christian Association; a, Jas W McLaughlin.

Grandin road, W H, stone foundation for chapel; cost, $9,000; o, Sisters of Notre Dame; a, E F Durang.

Race st, bet 6th and 7th sts, 5-story br bldg for store purposes; cost, $15,000; o, Wm H Harrison; a, Jas W McLaughlin.

A O Elzner, architect, reports the following plans nearing completion:

2½ story br and stone res for Dr A Springer at Norwood; 50x60 feet, to cost about $30,000.

A double 2½-story br res for Mrs Miller and Mrs McGraw, on Jane st, Walnut Hills, to cost $10,000.

COLUMBUS, O. — Buttles av, br and s dwell; cost, $6,000; o, Theophilus Rees.

Buttles av, 6 dwells; cost, $10,400.

DENVER, COL.—17th bet Erie and Boulder, br terrace; cost, $18,000; o, Evan G Owens; a, Alex Casin.

26th cor Arapahoe, br terrace; cost, $20,500; o, E Heilder; a, H F Lee.

Lafayette bet 21st and 22d avs, br dwell; cost, $10,000; o, T L Cachcart; a, Lang & Pugh.

Goss cor Kent sts, 2 br dwells; cost, $21,000; o, Mrs Whitridge; a, J J Huddart.

Penn bet 10th and 11th avs, s dwell; cost, $45,000; o, J A McMurtrie; a, I Hodgson.

THE Editor of THE ENGINEERING AND BUILDING RECORD is always glad to receive items of news for the Contracting News Department. But such items are not considered news except when the prices and particulars of the award of a contract are given.

The announcement that ——— has sold ——— to ——— without giving the *prices* and particulars concerns only the buyer and seller. Such notices are always excluded, except in the case where a certain firm is stated to have taken a certain contract, the execution of which would require that they should buy certain materials. Such an item would be used if deemed of more than local interest, because it would suggest to some readers the possibility of their making a sale or securing a subcontract.

GRAND RAPIDS, MICH.—East st, near Cherry st, additions and alterations in a fr church bldg; cost, $5,000; o, East St M E Church Society; a, W G Robinson; b, not let.

Plainfield av, 3-story and bmt red pressed br block with galvanized iron bays; cost, $10,000; o, M Shanahan; a, same as above; b, John Youngbacker.

Cor Ionia st and 6th av, br church bldg with finished bmt; cost, $7,000; o, Calvary Baptist Church Society; a, same as above; b, by the day.

HARRISBURG, PA.—North Front st, br and s res; cost, $7,500; o, W Calder, Esq; b, Wm Gates.

South Front st. br and s res; cost, $,.-000; o, Mrs Elbridge McConkey; b, Wm J Ball.

North 2d st, 4 s dwells; cost, $14,000; o, A J Stewart, Esq; b, B F Kimes.

LANSFORD, PA.—A church, to cost $8,000 is to be erected here. Address W D Hill, architect.

LOWELL, MASS.—East Merrimack st, 6-story br store house; o, Mass Corporation; b, not let.

Kirk st, high school; cost, $150,000 o, City of Lowell; a, F W Stickney; b, not let.

School st, 2-story fr store house; o, Boutwell Bros.

MANOA, PA.—A large opera house is to be erected at this place.

MEADVILLE, PA.—A hospital to cost $10,000 is to be erected at this place.

MILWAUKEE, WIS.—Cor Martin st and Junean pl, res; cost, $25,000; o, L A Field; a, A Fielder, of Chicago; b, John Jones.

MINNEAPOLIS, MINN.—2714–22 Washington av, fr block of flats; cost, $30,000; o, a and b, J Hanson.

601–3 Harrison st, br store and flats; cost, $8,000; o, a and b, E. F. Gagnon.

Cor of 4th av and 5th st, br elevator; cost, $18,000; o, City Elevator Co; a. Barnett & Record

PEORIA, ILL.—Wechselberger & Reeves, architects, have completed plans for a $12,000 residence for Newton Mathews. It will be heated by hot water.

READING, PA.—4th and Douglas, 2-story s stable; cost, $7,200; o, C Wilhelm; a, Mr Lansdale; b, Mr Jacobs.

11th and Douglas, 15 3-story Queen Anne houses with all improvements; cost, $3,000 each; o, Tucker & Rehr; a, Smith & Bro; b, Angstadt.

Center av, s church; cost, $12,000; o, Rev Stoner; a, same as above.

Elm, 3-story green s front; cost, $9,000; o, H Long.

Douglas and 2d, 3-story Queen Anne houses in pairs, 3 pairs; cost, $6,000 pair; o and a, C Stoltz.

SALT LAKE, UTAH.—A hotel is proposed for Garfield Beach, at this place. C S Mellen, Traffic Manager Union Pacific Railroad, Omaha, Neb., can give information.

First South st, 5 story br bldg; cost, $60,000; o, H Dinwoody; a, Carroll & Kern.

SOUTH BETHLEHEM, PA.—Lehighton st, fr and shingle bldg; cost, $8,000; o, J S Lentz; a, A W Leh.

ST. PAUL, MINN.—Cedar near Aurora, 2-story br ven dwell; cost, $10,000; o, Maurice Lyons.

E 7th, near Joellson, 3-story br block; cost, $12,000; o, E E Davidson.

Laurel av cor McKubin, 2-story br addn to school bldg; cost, $25,000; o, Board of Education.

TOPEKA, KAN.—Stone addition to Campbell University at Holton, Kan; cost, $12,000; a, H M Hodley; plans not completed.

UTICA, N. Y.—The trustees of the Masonic Home and Asylum met in this city August 27 and accepted the modified plans of Architect W. H. Hume, of New York City, for the building of the home. The plans will be on exhibition at the office of the Secretary, at the Temple in New York, and also in this city, until September 20, when the bids will be opened at the Temple in New York. Bidders will be required to give $50,000 bonds for the faithful performance of the work, which is to be commenced at the earliest possible moment after the contract is let. John Y. Culyer, C. E., of Brooklyn, N. Y., is preparing plans, etc., for the grounds around the edifice as well as for the sewerage and drainage systems.

WEST CHESTER, PA.—A hotel to cost $100,000 is projected for this place.

WHEELING, W. VA.—Br and s brewery; cost, $150,000; o, Schmulbach Brewing Co; a, Kerstner & Co, Chicago, Ill; b, not given out.

WILKES BARRE, PA.—202-15 E Market, 9 br warehouses; cost, $15,000; o, S L Brown and Williams Bros; a, Kipp & Podmore; b, E T Long.

BUILDINGS.—There is nothing over $7,000 in value to report at the following places: Ogdensburg, N. Y.; Geneva, N. Y.; Worcester, Mass.; Charleston, S. C.; Chester, Pa.; Binghamton, N. Y.; Canton, O.; Clinton, Ia.; Dennison, O.; East Saginaw, Mich.; Youngstown, O.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22. NUMBER 14. PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.

NEW YORK, SEPTEMBER 6, 1890.
LONDON, SEPTEMBER 20, 1890.

SINGLE COPIES, TEN CENTS. Subscription, $4.00 per year in advance, post paid. IN AMERICA.
Subscription, 25*s*. per annum in advance, post paid IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.

25*s*. in GREAT BRITAIN. Other Foreign Countries $6.

Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $6; China, Japan, Sandwich Islands, Mexico and Cuba, $6; South America, $6.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

A LESSON FOR ARCHITECTS.

THE lesson for building departments which we drew in a recent issue, from the structural defects of a theatre building in Brooklyn, by no means exhausts the suggestiveness of that affair. It contains a valuable lesson for architects as well. A costly building, to whose security many hundred people are, almost every night, to be invited to trust their lives is found, in some particulars at least, to be weak in design and much slighted in its construction. How did it happen? It is easy to say that the architect was careless or incompetent, but the question then arises, how does an incompetent man come to be entrusted with such important work, or, if competent, why is he careless? We may find the answer in considering the requirements of a building and of the man who wants it built.

Every building should display wisdom in its arrangement, strength in its construction, and beauty in its design. Of the first of these requirements the owner is perhaps as good a judge as anybody, and he is apt to think that he is of the last also, at least he gives some attention to the subject, and knows, or thinks he knows, what he wants; but about structural strength, without which everything else is useless, he usually knows little or nothing, and takes it for granted that his architect will attend to all that. Nor is the building itself apparently more obtrusive in requiring attention to its structural features. If it is awkwardly arranged, or unsatisfactory in appearance, the architect will speedily hear of it; but it may be dangerously weak and nobody ever find it out, for the ordinary factors of safety require such a surplus of strength that a considerable deviation from what would be regarded as safe practice may occur without causing disaster

The question of strength is, therefore, not forced upon the architect's attention, and the temptation to slight it is increased by the fact that it usually entails greater cost than do either of the other requisites. Patient planning may secure convenience and artistic skill, a fine appearance without materially increasing the cost, but strength requires good workmanship and sufficient material, as well as careful calculation, and these take time and money. Furthermore, an architect gets no credit for mere strength; that is taken as a matter of course. His reputation depends on the convenience and beauty of the structures he designs, provided they do not fall down or exhibit dangerous weakness.

It is easy, then, to see how an owner may choose an architect who is ignorant of the principles of good construction, or how an architect, who knows how to make a building strong, may be tempted to neglect to do so. Another reason why structural weakness may sometimes be overlooked by the architect lies in the fact that the artistic and constructive faculties are not always, perhaps not often, combined in the same individual. Indeed, they are sometimes considered antagonistic, as shown by the remark of a young architect, who has since grown wiser, to the effect that he did not "wish to know anything about construction as it would spoil his artistic taste." In such cases it is to be expected that appearance will be paramount, and that the artistic architect will, even if competent to perform them, shrink from the tedious and uninteresting calculations that are often necessary to ensure the safe and economical disposition of material. It may be said, then, that if the convenience of a building depends on the cunning of the architect's brain, and its appearance on his training of hand and eye, its strength rests mainly on the tenderness of his conscience

An architect has, doubtless, as tender a conscience as that of any other professional man, and when it has been sufficiently awakened to lead him to ask, "What shall I do to be saved from having my building fall down, or even having it dangerously weak?" the answer is simple. Have some competent person design its structural features or revise your plans. Even if you are perfectly competent to do it yourself, it will be better in an important structure to get outside advice, for it is difficult to pursue two such different objects with equal zeal, and the temptation to neglect one for the other, or to permit the requirements of one to obscure those of the other will be great, and so will be the corresponding advantage of having one person give his whole attention to structural considerations, apart from everything else. If you are not competent to do both, of course this advice goes without saying.

It is gratifying to note an increasing tendency towards this rational division of labor on the part of the better class of architects. In describing the office routine of some leading practitioners not long since, we had occasion to note the fact that, in several instances, the chief of staff was not an architect at all, but an engineer, and when a prominent New York architect had occasion, a few years ago, to take charge of the erection of one of the finest office and insurance buildings in that city, he employed a competent civil engineer for a year or more, at a good salary, to design its structural features and superintend its erection. Such instances could easily be multiplied. The young architect cannot, of course, do this, but he can do what is just as good—namely, consult a competent civil engineer in any case of difficult or important construction. This practice ought to result in making a good business for some engineers who will qualify themselves to advise with architects on all the various engineering problems from foundation to roof, and from heating to sanitation, that may arise in the construction of an important building. It would insure good construction and leave the architect free to give his entire attention to the subjects more congenial to his taste and training.

It should result, also, in securing finer, stronger, and more convenient buildings in which to live, to work, or to seek recreation.

STEAM METERS.

ONE of the questions which suggests itself every now and then is why some one does not produce a good steam meter. Every one who has had anything to do with the measurement of steam, particularly when used in the form of jets for heating and boiling liquids, has had to do considerable guess-work in getting at the amount used. Formulas for determining the flow of steam from orifices and jets, of course, abound, but simple calculation will show that the results obtained from the several current rules will vary to a surprising degree, though the conditions may be exactly alike in all the chosen cases.

A reliable meter would not only do away with this uncertainty, but would commend itself highly considered from the standpoint of convenience alone. Nevertheless there is not now on sale, so far as we know, a single appliance worthy of the name. Some of those which were on the market were, in fact, absolutely untrustworthy, and required such an amount of testing in order to find out what their indications really meant that they were entirely impracticable. A good meter, capable of measuring with reasonable accuracy both large and small flows of steam, and at suitable variations of pressure, still remains to be brought out, and would, no doubt, bring profitable returns.

A PNEUMATIC TUNNEL ROAD UP THE JUNGFRAU.

The plan proposed by Herr Trautweiler, of building a single tunnel with a switch in the middle of the ascent, the cars to be operated by a cable, has been held in abeyance, according to *Kuhlow's*, while the plans of Colonel Locher have been under examination.

Colonel Locher proposes to build two parallel tunnels with a slightly curved profile, each 9.84 feet in diameter, up which cylindrical cars are to be forced by compressed air. Each tunnel is to contain three rails, two below and one above, securely fastened to the masonry in accurate position. After the rails are in place, the tunnel will be lined with cement and gauged to a perfect cylindrical surface by means of a revolving templet. The cars, 65 feet long and to seat 50 people, have their wheels attached to the platforms and present an end area of about 75 square feet. They will weigh, with the 50 persons, about 11 tons, and it is estimated that to keep the car at rest, on a grade of 70 per cent., a pressure of seven tons, or 184 pounds per square foot, must be applied. An increase or decrease of the pressure by 220 pounds is to govern the ascent or descent of the cars. This combination is claimed by Colonel Locher to give the safest mode of propulsion on such grades, as the brakes are set so as to press the wheels against the rails, and not only stop their revolution but increase their sliding friction, and, if they fail, an automatic set is to be thrown into use.

The length of the tracks is to be about 3¼ miles, and the time required for a trip, at 23 feet per second, is estimated at 15 minutes. The power is to be derived from three rotary fans, 21 feet in diameter, driven by turbines directly coupled to the fans, the axes being in one piece. It is estimated that about 1.971 cubic feet of air, at a pressure of 16.5 pounds per square inch, must be furnished every second, besides that allowed for leakage around the sides of the cars. This will be reduced to a minimum by means of rings of iron plate, spaced two inches apart, and projecting to within one inch of the sides. For this 2,835 cubic feet are to be provided, an amount which can be furnished by two fans 21 feet in diameter, making 310 revolutions a minute. These plans have been pronounced feasible in every respect by four of the largest engineering firms in Europe.

Kuhlow's, however, doubts if the project will be remunerative, as, for topographical reasons, the tunnel will stop near a little plateau 1,200 or 1,500 feet below the top, the last 1,000 feet or so of the Jungfrau being a great needle, with nearly vertical sides, in which the tunnel would become a shaft, and the top, which is a mass of ice-covered rock, will not give room for more than 20 people.

PREVENTION OF ABRASION OF CREEK AND RIVER BANKS.

In a paper recently read before the Illinois Society of Engineers and Surveyors, E. T. Chamberlain explained that the wearing away or abrasion of creek and river banks may be caused by—

First, wave action; second, too great a velocity of the stream; third, an outflow of water through the substrata of quicksand that are generally found under alluvial lands. The water that, during a flood, fills all the beds of sand, running back to the river after the high water, carries with it the quicksand, causing the bank above to cave into the river and be carried away. Frequently the wearing away is done by a combination of all three of the above-named causes.

To prevent the injury by wave action nothing is better than a revetment of brush and stone. The mattress upon which the stone is to be thrown should be close enough to prevent the water from carrying away the soluble portions of the bank. Fascines, 10 to 18 inches in diameter, made of willow poles eight or more feet in length, are laid close together upon the bank, if above water, and the same well covered with stone. If the bank to be protected is submerged, the fascines are fastened together by wire or rope, so as to make the desired size (or section if too large for one mattress), then anchored and sunk to place by throwing stone upon the same.

Most of the abrasion of small streams is caused by too great a velocity of its waters. A few small spur dykes are the cheapest and most effective for such cases. The end projecting into the stream should point a few degrees up stream, from a right angle to the bank, so as to form a body of comparatively dead water above the dyke. For small streams a few large trees fallen into the stream, with small trees and brush to make all close enough to carry stone to hold it in place, will frequently be all that is necessary for a dyke. The dykes, as generally made by the United States engineers, are willow mattress alternating with plenty of stone, and, when raised to the desired height, all well covered with stone, care being taken to have an apron extending from the lower side, at the bottom, or the water falling over the dyke will undermine the same.

The injury from the third cause is found only along banks of the large streams, or on embankments composed in part of quicksand and subject to one side only being covered with water. For the river bank the revetment above described, or, if room in width of the stream, some dykes so located as to deposit coarse river sand against the affected bank, will be necessary.

Mr Chamberlain described a cheaper substitute, used upon a bank of about half a mile of the Mississippi River, that was troubled by all three of above mentioned causes. The river bank was 6 to 10 feet high—and perpendicular—to the surface of low water, and thence about two feet base to one foot vertical for a depth of 8 to 15 feet, with a strong current, but recently directed so as to endanger, striking the upper end obliquely and following the concave bank until deflected towards the opposite shore.

As the river had encroached nearly to the base of the levee, something must be done, or a new levee, costing $8,000 to $10,000, must soon be made. Green timber and sand near by could be had for the asking. Large trees, with the tops entire—all that four mules could draw on frozen ground—were used. The first tier was placed with tops up stream and the butt kept close against the bank. After a good base had been secured, the top ends were turned down stream, and large trees, logs and brush (all green) were rolled off the bank until a wall of 5 to 15 feet in width was built higher than the bank. Then large stakes were driven into the bed and vertical bank as would best tie all together. Four dykes, about 80 feet long, and about 40 feet wide at base, and 15 wide at the top, which was above low water, were constructed in a similar manner. The dykes were weighted with a few boxes filled with sand. The work so constructed remained one year, and was covered with water once. All that had been completed as above remained, and the lower portion was found imbedded in sand and silt.

NOVEL PLAN OF RAISING WATER FROM A SHAFT.

W. Galloway described before the South Wales Institute of Engineers, a short time ago, a novel plan of raising water from the shaft sunk at Llanbradach by the Cardiff Steam Coal Collieries Company.

It was known that a considerable thickness of the Pennant sandstone series, which is invariably found heavily watered, required to be passed through, and surrounding collieries have heavy pumping fittings. The absence of any means of determining the probable quantity of water to be dealt with in sinking led to special provision for winding the water to the surface. The contract provided for certain allowances whenever the water exceeded 4,000 gallons per hour, whether pumps were provided or not. The largest quantity met with was 7,500 gallons an hour in the shaft bottom. Down to a depth of 135 yards the total growth was 9,000 gallons an hour, of which 5,000 gallons was walled out by brick and cement walling. It would have been impossible to proceed with the sinking without pumps had it been necessary to fill the water into the kettle by the ordinary means of bailing. Mr. Galloway accordingly devised what he calls a "pneumatic water barrel"

It consists of a cylindrical vessel of sheet iron, 4 feet 2 inches in diameter and 8 feet deep, closed at the top by an air-tight manhole door. The bottom is 5 inches above the lower edge of the cylinder, and has a circular hole in it 18 inches in diameter. This hole is closed by a faced valve of cast iron, mounted with a sheet of leather, capped and tightly clasped by an iron hoop. The valve is attached to a spindle by a ball and socket joint, by which it is kept in position, but allowed a certain amount of play so that it may readily accommodate itself to its seat. The cylinder is thus an air-tight vessel, the interior of which has communication with the exterior atmosphere only by means of a pipe, extending from close to the top of the cylinder in the inside, to the outside of the vessel halfway down. The outside end of the pipe is fitted with an instantaneous coupling identical with that used on the vacuum railway brake. In use the pneumatic water barrel is lowered into the shaft till its lower edge is under water in the shaft bottom. The interior is put into communication with a condenser air pump on the surface by attaching a flexible tube connected to the vacuum pipes in the shaft to the instantaneous coupling of the barrel. A vacuum equivalent to 20 to 22 inches of mercury is thus obtained inside the barrel, and the water rushes in through the bottom valve. A glass gauge tube on the outside of the vessel shows when it is full. The tube is detached, and the signal given to raise the barrel. When it reaches the surface a bogie is run under it, and it is lowered on a conical block of wood, which raises the valve, and the water escapes.

The Executive Committee of the Grant Monument Association, New York, have received plans from architects Carrere & Hastings, Charles W. Clinton, N. Lebrun & Sons, J. H. Duncan and John Ord.

PERSONAL.

City Engineer Charles A. Allen is busily engaged in the matter of providing for the abolishment of all grade crossings in Worcester, Mass.

Abraham Gottlieb, Mem. Am. Soc. C. E., of Chicago, has been appointed Consulting Engineer to the Chicago World's Fair Commissioners.

J. Wechselberger, formerly with Burnham & Root, architects, of Chicago, and William H. Reeves, a graduate of the Champaign, Ill., University, recently opened an office at Peoria, Ill.

Harry P. King, of Peoria, Ill., and W. A. Dickerson, of Dubuque, Iowa, have formed a partnership under the name of King & Dickerson, with offices at Peoria, intending to do an engineering and contracting business.

H. C. Merrick was recently elected to the office of City Engineer of Binghamton, N. Y., by the City Council. A. A. Caille, however, at present holds the office under appointment by the Mayor and has refused to transfer it.

Major George W. McNulty and H. Waller Brinckerhoff, civil engineers, of New York City, are associated in the engineering work, including the preparation of the plans, for the inclined planes and hoisting machinery of the Dunderberg Spiral Railway, on the Hudson, of which G. H. Vedeler is Superintending Engineer.

A petition was presented to the Mayor this week by O. H. P. Cornell, of New York, asking that he be appointed to the place on the Aqueduct Commission made vacant by the death of Walter Howe. These names were affixed to the petition: Andrew D. White, Thomas L. James, Ellis H. Roberts, W. J. Arkell, Dr. A. W. Lozier, H. L. Hotchkiss, John J. Simpson, Charles H. Blair and Walter Katte. Letters from E. F. Winslow, A. Bonzano, Silas B. Dutcher, E. L. Conthell and George H. Sharp, of Rondout, praising Mr. Cornell's abilities as an engineer, accompanied the petition. Mr. Cornell has been twice a candidate for State Engineer on the Republican ticket. He is a son of ex-Governor Cornell.

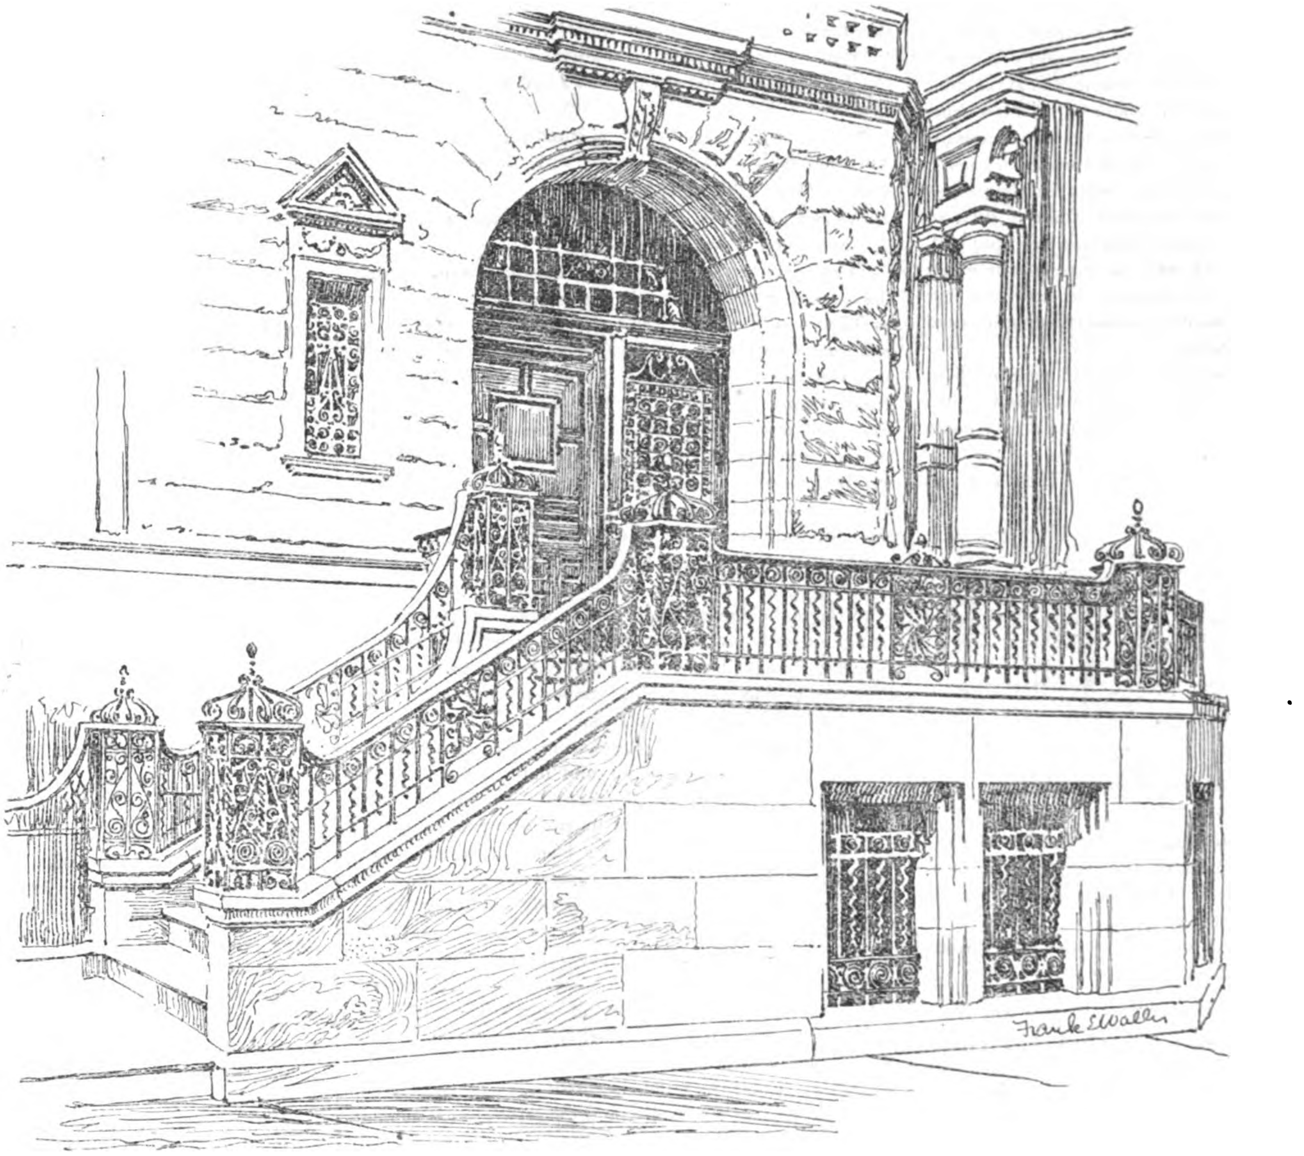
ENGINEERING SOCIETIES.

THE first regular meeting of the season was held by the American Society of Civil Engineers on September 3, with President W. P. Shinn in the chair. Regular business was transacted, and a paper on "Notes on a Mountain Slide," by William G. Curtis, was read and discussed. The following candidates were declared elected:

Members.—August William Bœke, City Engineer, Kansas City, Kan.; Charles Gleason Elliott, Engineer for drainage of large farms for private parties and for districts organized under the laws of Illinois, Gilman, Ill.; Charles Malon Mills, now Assistant Engineer the Phœnix Bridge Company, Phœnixville, Pa.; Joseph Allen Powers, Manager Troy Electric Light Company, with charge of Steam and Electrical Plant, and Village Engineer for Lansingburgh, N. Y.; Henry Hodge Quimby, for six years with Phœnix Bridge Company as Engineer in charge of Designing and Constructing Bridges, Viaducts and Buildings, Phœnixville, Pa.; Job Meade Tobias, Chief Engineer Cartagena and Magdalena River Railway, Cartagena, U. S. Columbia.



CITY STOOP.—R. H. ROBERTSON, ARCHITECT, NEW YORK.

Juniors.—Francis Winthrop Scarborough, Assistant Engineer Maintenance of Way Department Chesapeake and Ohio Railway, Richmond, Va.; John Joseph Tallon, Principal Assistant Engineer North Hudson County (Elevated Cable) Railway, Hoboken, N. J.; Wolfgang Gustave Felix Triest, with A. P. Boller, M. Am. Soc. C. E., New York City, address Paterson, N. J.

A CIRCULAR has just been sent to the members of the American Society of Mechanical Engineers, directing their attention to the Mechanical Engineers' Library Association, and urging them to become fellows of this association, which implies to give it financial support. It has not seemed judicious to meet the opportunity for enlarged usefulness now opening before the society by arbitrarily raising the dues, but the plan of Library Fellowships will enable all to accomplish the same result without making undesirable changes of the rules.

PLASTER HOUSES.

AN innovation in building is to be tried at Pittsburg, Pa. F. Lingenfelser, a prominent master plasterer of the city, is said to be the prime mover in the project, according to which the framework of a house is erected the same as is done for any frame building. For larger buildings, iron or steel may be used.

After the framework is complete, a metal lathing is nailed on the studding, completely covering the sides of the building, excepting doors and windows. The meshes of this lath are diamond-shaped, and the surfaces are turned at an angle. This lath is coated with a mixture of mortar and cement. On that is put an inch or more of cement, which is finished and lined in imitation of any kind of stone. The cost, it is claimed, will be but little in excess of that of the customary methods.

THE TORONTO, CAN., SEWERAGE SCHEME.

CITY ENGINEER JENNINGS, of Toronto, Can., has submitted a comprehensive report on the Toronto trunk sewer scheme, agreeing, in the main, with that handed in by Messrs. Hering and Gray. The total approximated cost of construction, as determined by Mr. Jennings, will be $1,632,538, exceeding the estimate of Messrs. Hering and Gray by $161,490.

Accompanying the report are tables showing the length, dimensions, capacity and cost of the proposed system of sewers, also the maximum population and area which they will serve. There is also a plan giving the course of the sewers recommended.

A CYLINDER head in one of Nashville's $100,000 Holly-Gaskill engines is cracked, and the new pumping station is idle.

PIPE-LAYING IN MARSHY GROUND.

JOHANN FRIEDRICH FISCHER, of Worms, Germany, has patented a method of, and apparatus for, pipe-laying in marshy or swampy ground, during inundations or in other similar circumstances, and for forming foundations in wet ground. *Kuhlow's Review* explains that in laying a line of pipes in accordance with this system, a trench is excavated to the water level with a wide bearing on each side for laying the sleepers and rails, on which the machines have to travel. As soon as the trench is ready, a line of pipes is put together and made tight. The next stage is to erect a sinking frame or caisson, constructed of sheet iron with angle-iron frame and stays, open at top and bottom, and placed above the connected line of pipes, which are suspended in slings. The line of pipe is covered at each end with porous caps, which permit the water to enter, but not the dirt and soil. The pipe and the sinking frame are then lowered by digging away the ground from under them, and when the proper depth has been reached and the end of the pipe joined on to the portion previously laid, the sinking frame is withdrawn by hydraulic power. The caisson is made in sections; so that, while the rests are taken up, the portion covering the pipe ends may be left, if so desired, until the joint is made. Herr Fischer prefers to make the joints with India-rubber rings on a spigot which would allow for any slight irregularity of the ground. The invention has nothing to do with the freeing of the trenches from water, but merely suggests a way for substituting iron framing to keep a trench open, instead of the timbering usually employed for this purpose.

TAMPA, FLA., has a garbage cremator capable of destroying forty cubic yards of material in twelve hours with about three-quarters of a cord of wood.

THE MAINTENANCE AND OPERATION OF WATER-WORKS BY PRIVATE COMPANIES.

SOME time ago Messrs. Howland & Ellis, civil engineers, of Boston, Mass., prepared a pamphlet, entitled as above, and giving, at length, descriptions of the various books of record and account, as well as of the numerous forms, reports, etc., to be used in different cases.

The wide interest of the subject and the fact that the pamphlet had but a limited circulation have suggested the desirability of reprinting it for the benefit of our readers. The pamphlet, as will be understood, treats only of those matters pertaining to the business of the companies, and does not touch on the mechanical and engineering departments.

The experience of our readers will doubtless suggest points for discussion, and this we invite.

In all business, a definite system of procedure must be established and followed, and especially in the business of supplying water to a municipality, where the customers are from all walks of life and their personal and business customs and habits are so varied. It is, therefore, absolutely necessary to have a standard of procedure that will best satisfy the largest number of persons, and at the same time protect the interests of the company. In too many places a large number of the people look upon the water department, whether public or private, as a common enemy, from which it is perfectly right to obtain, in almost any manner, as much as possible and return therefor little or nothing. The rates to be charged are liable to, and will, vary in different localities, as well as some of the minor methods of transacting the business of the company, but the general business system of all private companies need not vary on account of locality.

There are, probably, few places that will employ all of the books, forms, or accounts given in what follows; but, whenever applicable, they should be used for the purposes and in the manner indicated.

The account books necessary. Messrs. Howland and Ellis enumerate as follows·

No.	Name.	Record No.
1.	Application Book	924
2.	Rate Book	925
3.	Day Book	926
4.	Accounts Receivable Book	927
5.	Alphabetical Index	928
6.	Street Index	929
7.	Invoice Book	930
8.	Cash Book	931
9.	Journal	932
10.	Ledger	933

These books are all of uniform size, with pages 13¼ inches long and 8 inches wide.

The first six books relate wholly to the detailed records of the customers and earnings of the company; the seventh covers the expenditures; while the last three are the business books of the company.

There will also be several books of record and various blank forms to be used, which will be treated of later.

1. APPLICATION BOOK. 200 leaves. Record No. 924.

The pages of the Application Book should be paged on the left-hand page only, with even numbers, the first one being numbered 0. Each should have the printed form of application at the top, while underneath should follow suitable *numbered* rulings for *twenty* applications to fill out; thus each numbered page will contain the numbers of the applications that commence with the figures of the number of that page, and all that occur before the figures of the number of the next page—*i. e.*, page 6, will contain numbers 60 to 79 inclusive, while the next page, No. 8, will commence with application No. 80 and end with No. 99, etc.

Each book will thus contain 4,000 applications, and will be numbered on the back and side, accordingly.

In cases of tenement houses, flats, blocks, etc., occupied by several parties, but having only one street number, except as below, only one application need be received, and that from the owner, who must become responsible for all the service supplied to the premises. If he desire the tenants to each pay their proportion of the bill for the whole, he must make application for each, have separate sidewalk stops, service pipes, and other fixtures for each, and separate bills will be made out against each tenant having a separate stop, but if the bill is not paid the owner will not be relieved from paying the whole bill, and, if he refuse, the water will be shut off, and not again turned on to the premises unless the bill, with charges, is paid, even if a new tenant moves in.

In cases of blocks divided by party walls, and having separate entrances and numbers, each number should be treated as a separate property; and one or more applications must be made for each such block.

In supplying applicants, one tap at the main may supply two or more; but there must be at the sidewalk, or curb line, one shut off stop and box for each applicant or separate customer, and no more, of which the company takes cognizance. So the number of customers will always be the same as the number of service stops and boxes; and the number of the latter shall be called the "stop number," and be the designating number of the customer through all the books.

If the owner cannot make an application in person, then he must, in all cases, fill out and sign one of the regular blanks furnished, authorizing some one else to sign for him; and such authorization must be numbered with the number of the application and the stop number, and then placed on file.

An application should be made for each private fire hydrant, stand-pipe, or sprinkler, when the same requires a separate connection with the mains, and is used and paid for, for fire protection only; and each will have a stop number.

No large special fire hydrants, stand-pipes, or sprinklers will be allowed to be connected with the works and the water used paid for at meter rates.

2. RATE BOOKS. 500 pages in each book. Each page numbered. Record No. 925.

The pages should be ruled and headed, proportioning the number in each book for fixture and meter customers as the size of the works and the basis of charges in use will render necessary. In places having a population of 10,000 or over, separate books should be used for the two kinds of rates. When more than one book is used continue the numbers of the pages from the first into the second, from that into the third, and so on, so that there will be but one rate page for each number, no matter how many books are used. Make all entries in the order of the stop numbers. They will not be continuous, for some will be fixture and some meter rates, but preserve the order.

In the main headings the owner's name should appear, being crossed out and the new one inserted when the property changes hands—the number and name of street, the dates of the application, number of stop, etc., all to be filled in in their proper places.

In the first column on the fixture rate pages give the date of turning on the water and dates when rates are changed, etc.; in the second column designate each separate fixture in use, giving it its proper name and size; and in the third column give its location, together with any general information or description thought necessary; in the last columns fill out the quarterly and annual rates.

Whenever there is any change in the fixtures, make the necessary corrections or additions, cross out the old rates, and make the new ones so as to have all old figures for reference, but only the present live ones will be used.

Public hydrant rentals: The last three pages of the fixture rate book will be devoted to the account of public hydrants. Enter the number of hydrants paying different prices per annum separately, and the gross annual amount of each class in the annual column. In the columns to the left, enter the monthly, quarterly, or semi-annual amounts due as per contract with the municipality. Correct these entries whenever any change is made in the number of hydrants.

There will be found plenty of room on each page for all data in relation to each customer, and to make necessary minutes as to penalties, times of turning on and shutting off of supply; and each record should be corrected once a quarter, so that the amounts shown in the last columns will give the exact amount of the quarterly and annual rates that the customers pay.

3 DAY BOOK. 270 pages (3 quires), all numbered. Journal ruled. Horizontal ruling 3 to the inch. Record No. 926.

In this book enter the details of charges for materials and labor furnished or done for any one at any time, whether service pipe work or repairs on the same.

All entries are to be made chronologically and fully, so that, in case the charge is ever disputed, the details can be shown.

The total charges each month must agree with the footing of the services and repairs column in the Accounts Receivable Book.

4 ACCOUNTS RECEIVABLE BOOK. 360 pages (4 quires), all numbered. Record No. 927.

On the last of each month, after all bills, or accounts receivable, which are due and payable on the first of the next month, have been made out, they will be entered in this book. In entering them; their numerical order must be observed, and quarterly enter every stop number; and then, when the names and amounts are filled in, any omission will be noticeable, and it can be looked up. If it is a dead number, so note it; but, if any bill has been overlooked, make out one, and properly enter it.

Enter the amounts in the proper columns, and carry footings forward from page to page for journalizing. "Fixture rates" and "meter rates" should be added together, then the combined amount, as well as the footings of the other columns, journalized and posted to the ledger.

Bills for hydrant rentals made out against the municipality will, when due, be entered at the end of the month's entries, and the amount placed in the miscellaneous accounts receivable column, with a note or heading to distinguish it, but bills for private hydrant rentals, and private fire protection of all kinds should be made out separately against each party, and entered in the private fire protection column.

If bills are made out and paid in advance of making out and collecting the regular monthly bills, the stubs must be used in place of the bills when making the proper entrie on the Accounts Receivable Book at the end of the month taking care at the same time to enter amount and date of payment in the proper columns.

In the "rebate" column, enter the amount of the rebates on all the bills entered on the same line. The subject of rebates, as well as the other entries, will be more fully treated in the details of the ledger accounts.

Each night when receipts are entered, from the stubs to the cash book, they should also be noted in the last two columns of the Accounts Receivable Book, giving date and amount of payment.

Except when bills are paid before they are due, they will not be entered on the Accounts Receivable Book till they are entered with the regular monthly bills, as before stated. Meanwhile, such stubs should be separately preserved in the cash drawer until entered on the Cash Book, and then kept until the end of the month, when they will be entered on the Accounts Receivable Book. After entry, all stubs should be filed away, each day and month's receipts in a separate package, and preserved till the bills they represent would be outlawed.

5 ALPHABETICAL INDEX. 270 pages (3 quires). Record No. 928.

The pages divided between the different letters in the usual proportion. All entries should be strictly alphabetical to the third or fourth letter if necessary.

In the first column give the name of the applicant, which should be the name of the owner. Next give the number and name of street, then the application number, then the stop number, then the page of the Rate Book where the details of the rate can be found. Against the stop number in the Record Book the details of the connection, including corporation cock, etc., can be found. Leave three times as many lines between names as a party has premises, so as to provide room to fill in the location of other premises owned by the same person, or the names of other parties whose alphabetical arrangement would bring them between.

6. STREET INDEX. 270 pages (3 quires). Record No. 929.

This book has a small index in the front in which to enter the names of the streets and give the number of the page in the book where the same can be found. The streets need not be entered in alphabetical order in the main part of this book, but space enough should be alloted each street to allow for all probable applications that there will ever be on that street.

In the first column give the street number. In the second column the name of the owner, then the application number, then the stop number, then the page in the Rate Book.

In making entries, have them come as far as possible in order of street numbers.

(TO BE CONTINUED.)

ACCORDING to the *Electric Age* there were, on August 1, 1890, 223 electric railways in operation and under contract in the United States and 4 in Canada. The same authority places the number of cable roads in the United States at 44.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

No. XCIX.

(Continued from page 136.)

THE FORTH BRIDGE CONSTRUCTION.

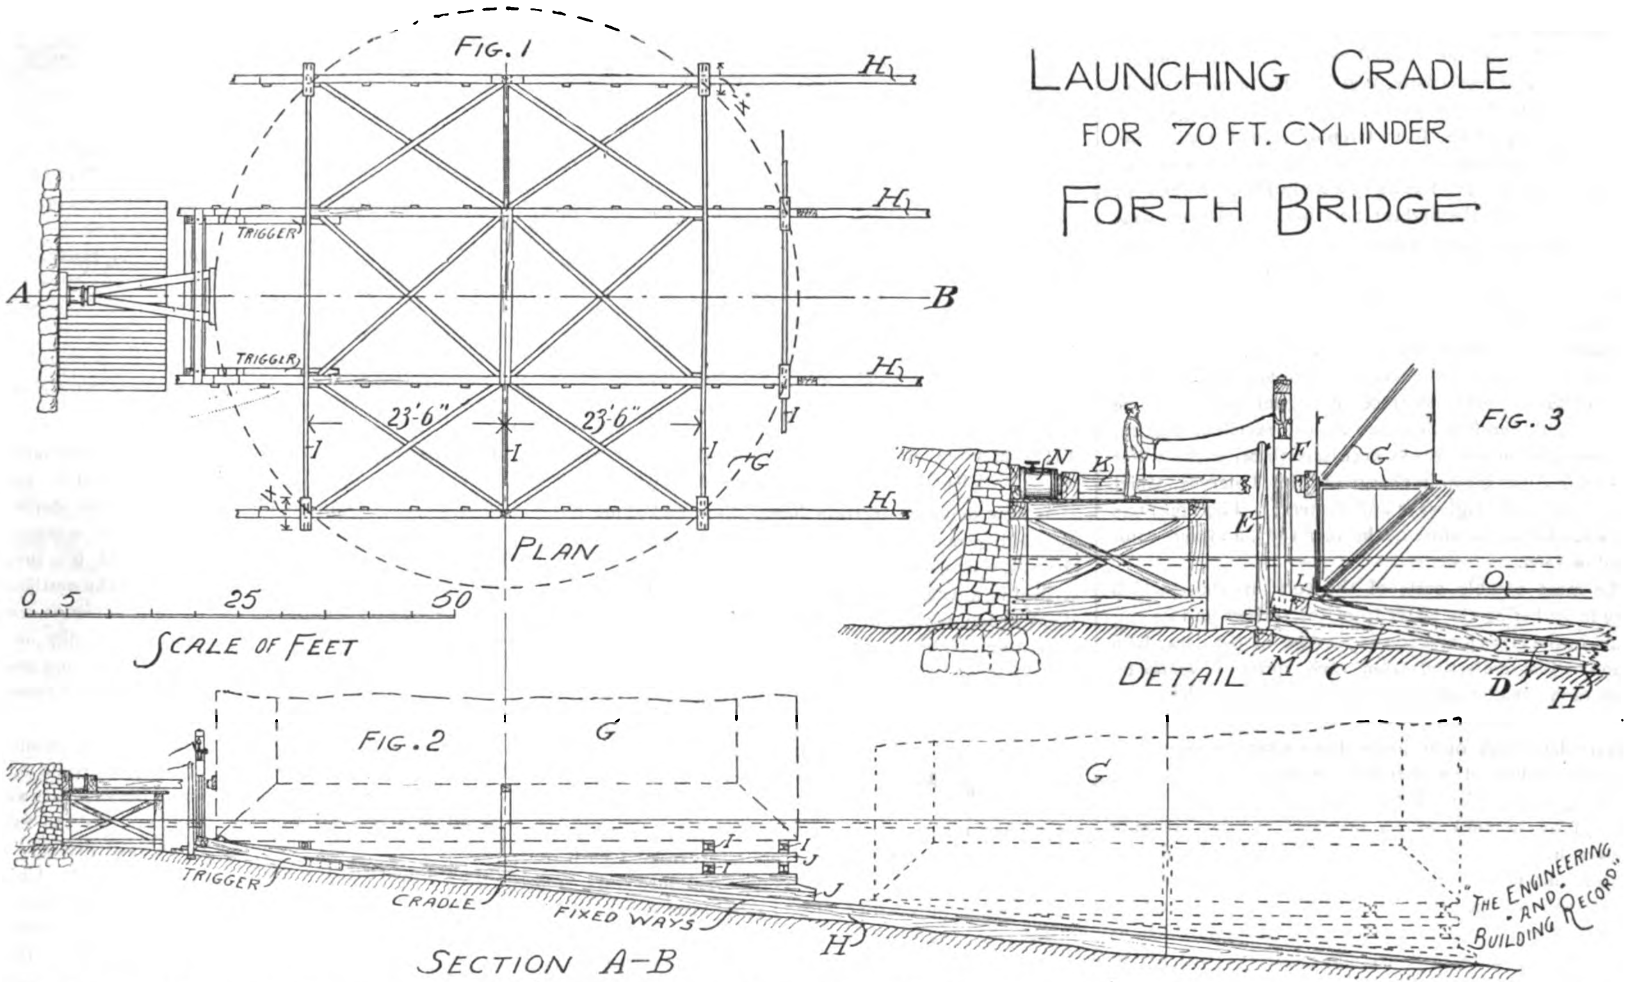
PART VI.—LAUNCHING THE 70 FOOT CAISSONS.*

THE pneumatic caissons which were illustrated on page 19, Vol. XVIII., were built on the shore adjoining the center line of the bridge, between high and low-water marks. The bed of the Firth of Forth at this point, after shelving somewhat rapidly to low-water mark, runs out about 1,700 feet with an almost level, muddy surface, giving only 18 feet of water at high spring-tides, where the caissons were built. The available depth was further reduced by the necessarily wedge-shaped cradle.

The caissons were built as high as possible, so that on reaching their site, and having been sunk to the bottom, it would not be necessary to add any more plates to their sides to keep out the sea at high spring tides, until the concrete required to sink them had been placed. The weight of the caissons so built, containing a small quantity of concrete as ballast, was about 400 tons each. When the building operations were completed as far as possible, four 15-inch hydraulic jacks were placed under the cutting edge and the caisson was raised to relieve the packings on the tops of the timber trestles, upon which the first portions of the girders, floor and shoe were erected, preparatory to their removal, the weight being supported the while on stacks of pitch-pine logs around the cutting edge.

Figure 1 is a plan of the caisson cradle, ways, etc., and Fig. 2 is a section and elevation at A B, Fig. 1.

The outlines of the caisson G are shown by the broken lines.



LAUNCHING CRADLE FOR 70 FT. CYLINDER FORTH BRIDGE

Four 12 by 12-inch pitch-pine skids, H H, etc., with smooth upper surfaces, were set at a uniform slope of 1 in 11 upon concrete blocks bedded in the ground. Upon these fixed ways the launching cradle was built, after the removal of the trestles already mentioned. It was composed of light wrought-iron beams, I I, etc., and 12 by 12-inch timbers, J J, securely bound together and provided with hard wood guides, bearing upon opposite sides of each pair of fixed ways, to keep the cradle to its path. Before it was allowed to rest upon the fixed ways, a few inches above which it had been put together, a thick coating of black soap and tallow was smeared upon the rubbing surfaces. The caisson was lowered upon the cradle by means of the four 15-inch hydraulic jacks already mentioned, and the triggers were fixed to hold it until the tide was high enough to launch it.

Figure 3 is a side elevation, on a larger scale, of one of the two triggers. Two 12 by 12-inch timbers, C, 13 feet 6 inches long, having rounded ends, butted into pieces of hard wood, D, bolted to the fixed ways. Bent iron straps, L, attached to their upper surfaces, caught the bottom angle, O, of the shoe. They were supported at their upper ends on movable steps, M, which prevented their becoming disengaged until the required moment.

All being ready for the launch, the remaining stack blocks around the cutting edge were removed. As the tide returned, the whole weight rested on the cradle, and its horizontal component was taken up by the trigger arrangement. At high tide, with the water standing about three feet above the cutting edge, on the signal being given the stops were drawn from beneath the trigger, and the weights, F, were let go (to disengage the triggers if they failed to fall by gravity), leaving the caisson and cradle free to move down the slip. If it showed any reluctance in moving it was assisted by means of the hydraulic ram, N, placed behind it. The cradle slid down the ways with its burden until the caisson drew sufficient water to float it off. The cradle remained under water, owing to the weight of iron used in its construction.

Two steam tugs were employed to tow the caisson to its site, where, after enough concrete had been placed in it to sink it to the bottom, the remainder of the plating was completed. The launching cradle was taken to pieces and kept for the next launch.

(TO BE CONTINUED.)

SOUTH ORANGE, Milburn and Short Hills, N. J., are to be supplied with water in future by the Commonwealth Water Company of Summit. The work of laying the mains, etc., will be done under the supervision of C. P. Bassett, of Newark, and the County Road Board. Contracts with the Water Company are to be made by the three villages named.

THE merits of disposing of garbage by cremation are shortly to be investigated by the New York Street Cleaning Department.

THE WATER SUPPLY OF MOSCOW, RUSSIA.

To most Americans, writes Consul Wertheim, of Moscow, to the Department of State, it will be utterly inconceivable how, within the present age, a populous city like Moscow, having close upon 800,000 inhabitants, could possibly have so long endured so great a privation as the scarcity of water, yet there is the fact that this town has managed to jog along for the last 50 years and still exists upon the scant supply of barely 1,500,000 gallons of water per diem. However, after a course of deliberation extending over a year, this vital question of providing the town with more water has been brought to a head. The municipality has issued a loan of about $3,000,000, bearing 5 per cent. interest, for the purpose of constructing a new system of water-works, and the first notice inviting public competition for the execution of the work has been published. Before entering any further upon the subject of reconstruction and extension of the existing old water-works of this city it may be of some interest to trace its history and origin.

During the reign of Empress Catharine II., somewhere about the year 1779, the city of Moscow depended entirely upon carriers for her water supply, brought from the outlying districts of the town. It is said to have been so bad that the Empress used to have hers brought for her all the way from St. Petersburg. On one of her Majesty's annual pilgrimages to the Monastery of St. Sergievo, overcome with the heat and fatigue of her self-imposed pedestrianism, she halted at Metistshe, a small village about seven miles northeast of Moscow, and, having quenched her thirst with some water obtained on the spot, her Majesty was so delighted with its purity and freshness that there and then she decided to utilize the source, that had so unexpectedly been brought under her notice, for Moscow. In June, 1779, an engineer named Bauer was commissioned to design a plan for conveying the water to the town, but his conduits of stone could not resist the effect of frost, and the work was abandoned. In the year 1820 another engineer projected a plan to supply the town with water from the river Moskva; but he, too, failed, and took his own life, in sheer desperation.

It was not before the close of 1834 that the existing water-works were executed by Baron Dervig, and the idea of the Empress of supplying her cherished old city with water from the Springs of Metistshe was successfully carried out. The water, obtained from a series of springs at Metistshe, is all that can be desired, and there is plenty of it. The fresh supply is to be obtained by sinking a number of wells of small diameter, conveying it by a 24-inch main to an intermediate pumping station, and thence to a water tower in the town. From this the distributing system will be supplied. The supply is now to be increased fro[illegible],000 to 4,500,000 gallons per diem.

GRENOBLE WATER SUPPLY.*

THE City of Grenoble is situated at the junction of the rivers Isire and Drac, and is overlooked by high mountains, whence many water courses, fed by snows and glaciers, and the lakes of the higher table lands take their rise. In spite of the exceptional topographical situation, Grenoble was provided until lately with an insufficient water supply, derived from some springs whose total flow varied from 14.300 gallons to 17,600 gallons a minute, insuring only about 35 gallons a day to each of the 55,000 inhabitants. Even this amount was reduced to 22 gallons at most in exceptionally dry seasons. The pressure was too feeble to rise even to the first stories in the lower wards. For many years the Municipal Council had been trying to remedy the situation, and many plans had been considered to furnish a volume of water sufficiently large not only for domestic uses but also for industrial means. One of these projects, by Mr. Carron, was to raise by means of hydraulic machines and bring to Grenoble, with 656 feet of pressure head, the water of the Boiron and of the Rive, the total supply of which was estimated at 660 gallons a second. Beyond the volume of 55 gallons for domestic uses, there would be 610 gallons, which, at a pressure head of 656 feet, represented 5,500 horse-power; but this was abandoned on account of the expense of construction and a probable deficiency in receipts to cover expenses. In 1882 the Council adopted another project more simple and less costly, that of the introduction of the water of the Rochefort Springs. These springs, situated about 6¼ miles from Grenoble, yield a minimum supply of 110 gallons a second, at a gravity pressure due to at least 166 feet head at all points in the city, thus affording supply to the highest buildings. The temperature of these springs remains always between 10 and 13 degrees centigrade, and the weight of the saline residue obtained by evaporation is only 1.077 grains per gallon, or 0.237 grains per litre, composed of silica; 0,133 grains of carbonate of lime, with traces of magnesia; 0.062 grains of sulphate of lime, and 0.031 grains of sulphates and alkaline chlorides, with no trace of organic matter. The water should therefore be called a most excellent quality. The execution of the works necessary to bring the water to Grenoble was given in charge of Mr. Thiervoz, Chief of the Service of Highways and Waters. The contracts were awarded at the close of the year 1883, and were completed in 1885.

The most notable parts of the work are those which relate to gathering the water from the springs and its collection in the cistern and to the passage of the Drac by a syphon. The collection from each spring is made by means of a small tank placed at its source, as shown by Fig. 1. The foundation of each tank is made of blocks of concrete laid with open joints from which a secondary concrete conduit of a diameter of 12, 16 or 20 inches, according to the size of the springs, brings the water gathered by the tank into a principal aqueduct, passing however first through a storage tank. The abutments, the vault and floor of the aqueduct are all concrete. At the extremity of the ground the collecting conduit ends in a cistern (Figs. 2 and 3) connected by the aqueduct, as shown in Fig. 4, with a syphon under the bed of the Drac. The syphon which has been adopted for the passage of the stream is composed of two vertical shafts about 105 feet deep and an elliptical horizontal gallery 260 feet long. In this syphon are placed cast-iron pipes which replace the concrete conduits at a little distance from the shafts. Between the pipes is left a sufficient space for the passage of a man, and they are supported on brackets 6½ feet apart. The shaft and the gallery have been sunken in the rock which form the bed of the Drac. The inner wall or casing received a covering 15 inches thick, at maximum, of quick setting cement concrete mortar. At the end of the syphon the cast-iron conduits are replaced by two twin concrete conduits which bring the water down the river to Pont du Calir, beyond which cast-iron pipes are again used. Concrete conduits were computed to be safe and economical at Grenoble for pressures up to 49 feet head, above which cast-iron was preferable. The complete cost of the collecting pipes for bringing and distributing in the city amounted to nearly 2,000,000 francs. To this may be added the cost of the erection of the upright columns and branches along the lines, which the city has taken the burden of, to the end of rapidly developing the number of grants and contracts. The cost per litre per minute, constantly flowing, is only 80 francs, so that the city can establish a greatly reduced tariff and fixes the tax at only 0.055 francs per cubic meter. The following table shows that this price is less than in many important cities which are provided with the water distribution:

	Cost, francs, per cubic meter.	Daily supply per capita.

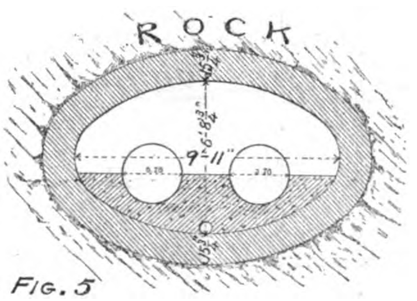

FIG. 5

GRENOBLE WATER SUPPLY

THE MANUFACTURE OF TILES AND SLABS FROM FIBROUS SUBSTANCES.

A NEW mode of treating hemp, jute, and other fibres for making materials for the manufacture of tiles, slabs, cisterns, boats, and other articles or structures, has been described in a recent English patent specification by B. A. Weatherdon, noticed in the London *Engineer*. The fibres are cut and boiled four to six hours in a strong solution of lime by steam at a pressure of from 20 to 40 pounds to the square inch. After being thoroughly washed, the material is passed to a pulping machine, where it is treated with alum about 7 to 14 pounds to the hundred weight, and in some cases with animal size, and in others with vegetable or other oils. From the pulping machine it is run into receiving or storing tanks, fitted with machinery for keeping the pulp in agitation, and whilst therein it can be dyed if required. Now the pulp fibre is pumped into vats, and from thence into wire molds, to be formed into slabs, blocks, etc., the liquor being extracted by suitable pressure. The slabs, blocks, etc., are brought into the drying-room, and when dry passed through solid steel rollers four to twelve times, steeped in a warm solution of alum, and again subjected to hydraulic pressure. Then they are brought into a bath of vegetable or other oil for four to six hours, and again pressed and steam rolled as many times as necessary. To finish the process they are dried in hot air, and in some cases passed through the rollers once more.

THE city authorities of Oxford, England, announce that they will make grants out of rates in accordance with the terms of the new Technical Instruction Acts for instruction in wood carving, drawing a scale for practical work and manual training in the use of tools for working in wood or iron. Report also comes from Rochdale of similar decisions in connection with cotton spinning and weaving, cloth weaving and plumbers' work.

CHICAGO is to have what, it is claimed, will be the largest building in the world in the new department store to be erected at State, Adams and Dearborn Streets. The building will have a front of 190 feet on State Street, 350 on Adams and 190 on Dearborn, will be 16 stories high, and will cost $3,000,000.

PROPOSED SEWERAGE OF WEST TORONTO JUNCTION.

THE town of West Toronto Junction, as its name implies, adjoins Toronto, the capital of Ontario, on its western side, covering about 1,200 acres on an irregular plateau, averaging some 150 feet above Lake Ontario, which is about 6,000 distant from the southern boundary of the town and toward which the plateau slopes at an average rate of one foot in a hundred. Two ravines extending up from the lake enter the town on its south side. On the north side the ground slopes toward Black Creek, which runs west to the Humber River, whose valley bounds the western side of the plateau, and which, flowing in a southerly direction empties into Lake Ontario. About half a mile east of the mouth of the Humber is the pumping station which supplies the town by direct pressure through a 12-inch force main, and has a submerged intake pipe extending out 700 feet into the lake.

Three different schemes of sewerage for the town are proposed in a recent report made by Willis Chipman, Civil and Sanitary Engineer, of Toronto. In each of them it is assumed that a population of 30,000 is eventually to be provided for; that 50,000 feet of sewers will be required to serve the present population, and that the storm water is provided for where necessary by separate sewers.

In the first, or scheme A as it is called, it is proposed to discharge by gravity all the sewage of the northern and eastern part of the town into the Dundas Street sewer of the city of Toronto, which extends to the limits of West Toronto junction and is of sufficient size and grade to serve for 50,000 people. The sewage from the ravines on the south and the high ground between them is to be collected at one point and treated chemically or pumped up to the Dundas Street sewer, and the same could be done with sewage from the high ground between the western ravine and the valley of the Humber. In the extreme eastern part of the town the "combined system" could be used, and for the northern part what Mr. Chipman calls the "restricted system," admitting rainwater only from roofs, cistern overflows, and in some cases from paved courts; but in the southern portion, where the sewage must be treated or pumped, the "separate system" will be required. The estimated first cost of this scheme is as follows, 10,000 feet of combined sewers, $30,000; 7,000 feet of storm sewers, $30,000; 40,000 feet of separate sewers, $60,000; 9,000 feet of mains to pumping stations, $20,000; 9,000 feet of inverted syphons across ravines, $20,000; 3 pumping stations, $30,000; total, $190,000; and the annual expenses as follows: Interest at 4½ per cent. on $190,000, $8,550; sinking fund to repay cost in 40 years at 4 per cent., $2,000; operating expenses at pumping stations, $1,250 to $3,450; total, $11,800 to $14,000, besides an unknown amount to be paid to Toronto for use of sewers.

In scheme B all the sewage is to be conveyed by the "separate system" to two or three points on the southern boundary of the town where, after being chemically treated in precipitation works, the effluent is to be conveyed, part to the lake and part to the Humber, or given a free discharge at the works. The estimated first cost is: 12,000 feet of storm sewers, $45,000; 50,000 feet of separate sewers, $75,000; 18,000 feet of mains, $35,000; precipitation works, $35,000; total, $190,000. Annual expenses, interest and sinking fund, $10,550; operating precipitation works for population of 5,000 to 15,000, $2,450 to $8,450; total, $13,000 to $19,000.

---

* Abstract from the Paris *Nouvelles Annales de la Construction.*

In scheme C it is proposed to remove the water-works intake and pumping station to a point nearly three miles southwest of its present location, where there is no likelihood of contamination by sewage, and then to sewer the town on the "restricted system," allowing most of the storm water to flow off by the natural water courses, while the sewage is conveyed to the lake by two main sewers down the two ravines and by another main to the Humber River. The outlets are to be submerged, and, perhaps, the present water-works intake could be used for one of them. The estimated first cost is, for 12,000 feet of storm sewers, $45,000; 50,000 feet of separate sewers, $75,000; 22,000 feet of mains to lake, $45,000; 10,000 feet of main to Humber, $20,000; total, $185,000. To this must be added the cost of removing the water-works as follows: New 18-inch main, $53,000; buildings and grounds, $10,000; intake, crib, etc., $4,000; contingencies, $3,000; total, $70,000, making a grand total of $255,000. The annual expenses are thus estimated: Interest, $11,475; sinking fund, $2,675; total, $14,150. No operating expenses, though it is possible that at some future time it may be necessary to purify the sewage before discharging it into the lake if Toronto introduces sewage disposal works.

Scheme C is recommended as probably the cheapest, in view of the fact that the water-works would have to be removed before long any way on account of the increasing impurity of the water at their present location; also the mains leading to the lake could be used to sewer the intermediate territory which, since the date of the report, it has been decided shall be included in the town limits; third, the trouble and expense of precipitation and pumping works would be avoided; fourth, the improved quality of the water supply will increase the number of takers and consequent revenue, and fifth, a revenue should be received for fire protection from the town of Munico through which the new force main would pass, and also from water takers there.

The report is accompanied by a map of the town and proposed sewer system.

BRICK AND TILE MAKING IN THE THIRTEENTH CENTURY.

T. HUDSON TURNER, writing in the London *Architect*, says: "There is no mention of bricks in any ancient building account which has hitherto fallen under the writer's notice. The art of working clay, one of the earliest arts, never fell wholly into abeyance in any country in which it had been once practiced. In England it survived the period of Roman dominion, during which it was extensively cultivated; in the Domesday Survey potters appear among other crafts incidentally enumerated; and people who could work at all in clay were likely to have made bricks. The silence of early records on this subject is the more remarkable because there are still existing buildings of the thirteenth century constructed in whole or part of these materials; it may be accounted for by supposing that bricks continued to be made in the Roman fashion, and passed by the name of tiles; if so, tiles and tilers are mentioned as early as the twelfth century, and constantly occur in documents of succeeding periods. In 1289 Edward I. began to enlarge the moat round the Tower; the clay thrown up was sold by the constable to certain tilers who worked in East Smithfield. In that year it produced only 20 shillings; but the alterations in the fosse were 12 years in progress, during which time the soil excavated and sold for the same purpose yielded an average yearly profit to the Exchequer of rather more than seven pounds—a very large sum if the relative value of money be considered, and equal, at least, to a hundred pounds a year of the present currency. From this fact we may infer that the London manufacture of tiles was considerable at the close of the thirteenth century. The art of brick making must, however, have been carried early in this century to a great state of perfection, if the specimens of molded brick discovered in Essex, and attributed to the fourteenth century, were really the produce of native skill. But as it is in Essex and Suffolk, counties devoid of stone, that we find the earliest brick buildings, it is by no means improbable that the materials were imported from Flanders, or manufactured on the spot by Flemish workmen, many of whom, it is well known, settled in the eastern counties at a remote time. It is certain that in the fourteenth century tiles were imported from Flanders; during the progress of the works at St. George's Chapel in the time of Edward I. numerous entries appear in the accounts of the purchase of Flemish tiles; 3,000 were bought on one occasion to line the chimneys in the chambers of the canons. Among the varieties of tile mentioned are channel-tiles, paving-tiles and rug-tiles It is rarely that old accounts supply any information respecting the cost or manufacture of those tiles which were employed in the construction of decorative pavements. Perhaps the earliest notice extant occurs in the building accounts of Thornton Abbey, in Lincolnshire, under the year 1313; it is for the purchase of earth to color the tiles of the church."

CAST *VS.* WROUGHT IRON FOR GAS MAINS.*

WROUGHT-IRON mains have some advantages not possessed by cast iron; owing to its greater strength, it will resist heavier internal pressures; less liable to fracture by sudden jars or by the disturbance of its foundation; can be joined together with less expense and greater speed; has fewer joints and can be laid in some situations where it would be almost impossible to lay cast iron; but it has two disadvantages considered serious ones—the first cost of the pipe, and the limited life, as claimed by the friends of cast pipe, when compared with cast iron in many kinds of earth.

In making comparisons as to the cost between wrought-iron screw-jointed pipe and cast-iron pipe, I have figured as to the price by carloads delivered in Ohio. One mile of 6 inch wrought-iron pipe would be $3,485. One mile of 6 inch cast iron pipe would cost $1,930; a difference in favor of the cast-iron pipe of $1,555 per mile. One mile of 8-inch wrought-iron pipe would cost $5,710. One mile of 8-inch cast-iron pipe would cost $2,700; a difference in favor of the cast-iron pipe of $3,010 per mile. The labor for digging and refilling trench would be at least 25 per cent. in favor of the wrought-iron pipe. The labor, lead, and yarn necessary to lay and join 8-inch and 6-inch cast-iron pipe would be about $400 for the one and $300 for the other per mile, while the labor and paint-cement to join a mile of 8 inch and 6-inch wrought-iron screw pipe would be about $150 and $120 respectively—making a difference of $250 for the 8-inch and $108 for the 6-inch, per mile, in favor of the wrought iron pipe.

The labor figures and cost of pipe, on the wrought-iron pipes, are based on the supposition that screw joints and standard weight pipe are used. If the patent leaded joints with the light weight wrought-iron pipe is used, the difference in the labor and lead account will be very much increased in favor of the wrought-iron pipe over that of the cast iron—there being a saving in lead alone of 2,800 pounds for the 8 inch, and 2,100 pounds for the 6-inch pipe, per mile; and as the pipe is so much less in weight and a less number of joints to be made, it can be handled and laid with less labor and with greater rapidity.

Mains have been made of cast iron ever since the general introduction of gas for illumination, and when examined or removed are found to be, as far as the texture of the iron is concerned, in as perfect condition as if just placed in the ground. There are, of course, exceptional cases, but not many, where the ground has become impregnated with some foreign matter, which will and does act on and destroy the cast iron in a comparatively short time.

As a means of comparison in the life of wrought and cast-iron (when neither are covered with a protective coating, and are equally exposed to a very severe test), I will cite an actual experience which happened on one of the short streets in our city: On this street was a 2-inch cast-iron main, with a number of service connections all ¾-inch, except one (1½-inch), which conveyed gas to a machine shop; going south from a certain cross street there was no difficulty whatever, but north from this point we were compelled to renew the service pipes every two or three years. Now, for the cause of this trouble: For a number of years this portion of the street had carried as surface drainage the sulphur or commonly called "copperas" water from several coal mines. The street was paved with limestone, the spaces between the stone filled with sand, but not cemented with tar or pitch. The drainage from the coal mines percolated through the sand and saturated the ground, which was composed of a mixture of clay and gravel, in which the 2-inch cast-iron main was laid. In 18 years the texture or composition of the pipe was so changed or destroyed that the pipe, on being removed, was so soft that it could be shaved with a common penknife as easily as the plumbago in our lead pencils; there was not strength enough in a 7-foot length to carry its own weight when placed upon supports at the ends. You will notice the life of cast-iron pipe as compared with wrought in this instance, after making due allowance for the difference in the thickness of the metal, is as three and a-half is to one.

In this connection I will quote a few lines received from Mr. Cantine, of the Alliance Gas Light Company, Alliance, O. He writes as follows:

"We had a 4-inch cast-iron pipe leading from our main line through the Pennsylvania Railroad Company's yard to supply their ticket office and eating house; and, after having been laid some six or eight years, we found it leaking badly. This pipe was extra heavy and of sufficient weight to be known as water pipe. The ground in which it was laid was mixed with cinders from locomotive ash-pits. The action of the impurities in the cinders had rendered the pipe utterly worthless, it having no more strength than unburned clay. The process of decomposition is or would be much more rapid in wrought iron or steel than with cast metal. The contact of one cinder no larger than a walnut will eventually eat its way through any pipe."

I have called attention to these instances in the first two to compare the life of the two kinds of pipe under the same circumstances, and in the first and third to show that even cast iron may be readily destroyed when subjected to certain conditions.

Will not the question be asked, Why is it that one kind of pipe will last so much longer in the same kind of earth than will the other kind of pipe? A gentleman to whom I put this question suggested: Is it not that cast iron and wrought iron are different in their construction, different in their chemical formation? In cast iron, the particles of iron of which it is composed retain their crystalline or natural shape, and contains a proportion of carbon; these crystals are in nature hard, bright, and in a measure polished, and are more or less coated with graphite, depending greatly on the quality of the iron—all tending to preserve the metal from oxidation. In the manufacture of wrought iron a portion of the carbon is eliminated, rendering the metal softer; the crystal or natural form is broken up; the crystals are elongated or drawn out, presenting a stringy or fibrous appearance through the length of the metal. The graphite coating or protection of the crystals is removed, rendering the pipe more open to the action of the destructive agents.

Again: The question is asked, Why will the same kind of pipe last longer in one formation of earth than in another? Have you not noticed when your pipe, particularly cast iron, was buried in sand for a number of years, that a thin, hard coating impenetrable to almost anything had formed on the outside of the pipe? This coating forms to a certain thickness; there the decomposition stops. Nature in this case has provided a nearly perfect and perpetual protector. Is not this combination of sand and iron, which is almost like glass in its hard appearance, silicate of iron? And have you not further noticed that where this formation does exist there is no escape of gas unless it be at the joints?—the coating forming a gas-tight covering?

On the other hand when your pipe of either kind have been buried in white clay, the tendency has been to deteriorate, in many cases, quite rapidly. Can we not account for this in this wise? In nearly all cases white clay veins or banks, are overlaid with coal in some form; sulphur, in solution from the coal, saturates the clay, comes in contact with and surrounds the pipe; the sulphur having a strong affinity for iron, combines with it; sulphuret or sulphide of iron is formed and the pipe is destroyed, more or less rapidly, in proportion to the amount of sulphur. This same action takes place where the pipe is exposed to coal cinders, similar to the case referred to in the quotation from Mr. Cantine's letter, there the free sulphur in the cinder combining with the iron.

Again: If your pipe is laid in ground so situated as to absorb, or in any way to contain matter likely to ferment, near by, or in contact with the pipe, there is great danger; for, during the process of fermentation, carbonic acid is evolved. This acid is particularly destructive, and very persistent in its combination with iron; once it takes hold it never releases its grip until it has accomplished its purpose.

When the question is asked, "Which is the best material for street mains—cast iron or wrought iron?" we would likely answer at once, cast iron. Why? Because we have been accustomed to purchase the same for a great deal less money; it is cheaper, and it will last longer; and then we say again we have to renew our wrought iron services, and we do not the cast-iron mains. Have we not overlooked the fact that the wrought iron services are less than one half the thickness of the cast-iron mains; that where we have had occasion to make renewals, the wrought iron had been more exposed than the cast-iron. The services mostly gave out at gutter crossings, where the pipe was not of sufficient depth, and was exposed to air, and dampness, and frost. Is it not true that many of us have wrought iron services in use to-day, and in good condition, that were connected to our cast-iron street mains when gas was first introduced to our towns, 40, and in some cases 60, years ago? We know what to expect as to the lasting qualities of cast-iron pipe. We know that with cast-iron mains the leakage of gas will average as much as 10 per cent. This we gather from the reports received from a majority of the gas companies.

The wrought iron costs from 50 to 100 per cent. more than does the cast pipe. (This difference is greatly reduced in proportion as you get farther away from the points of manufacture). The wrought pipe, however, does not cost near so much to lay, and the saving in leakage will in a very short time balance the extra expense for the wrought-iron pipe. The most important question appears to be, Will the wrought pipe last? On the other hand, why not have our cast-iron pipe, which we think will last, properly coated with some material that will close the pores and protect the iron beyond a doubt; also, have the spigot end of the pipe turned or ground smooth so that a permanent and tight joint could be made.

---

* From a paper by Eugene Printy read before the Western Gas Association at St. Louis, entitled "The Best Material For Street Gas Mains."

IN connection with the Newark-Passaic sewage controversy, recently referred to at length in our columns, it is of interest to note that Professor Austin, of Rutgers College, who is making an analysis of the Passaic River water, a few days ago made an interesting experiment. He placed several corks and some deleterious matter in the river at the point where Passaic City sewers empty. In three hours and fifteen minutes the matter floated down the river to the Newark pumping station. Inasmuch as it requires six hours for the tide to run out the experiment would seem to indicate that Passaic's sewage floats miles beyond the pumping stations of Newark and Jersey City. Samples of the water were gathered and they will be used as evidence in the court.

EXPLOSIVES.

THE extraordinary importance which just now attaches to explosive substances, says *Industries*, London, gives special interest to the Fourteenth Annual Report of Her Majesty's Inspectors of Explosives recently issued. The report deals chiefly with blasting compounds, so that we have more information afforded us on that class which is described as flameless than on the other, characterized as smokeless, designed for ballistic purposes. The latter are of more recent origin, and for the most part have not yet passed out of the experimental stage.

The inspectors report that in the year 1889 seventeen applications for license to manufacture or import new explosives were received, and four applications were made for permission to add a new ingredient to an explosive already licensed. Eleven out of these 17 applications were granted. This is a large addition to the list in one year. It is instructive to read the description of these new explosives, as we learn in what direction the efforts of inventors have so far been successful. First on the new list is the Chilworth Special Powder, a gunpowder containing ammonium nitrate to reduce the smoke. Then follows Camphorated Gelatine, which explains itself; Ballistile is a smokeless powder invented by Mr. Nobel, and is essentially a blasting gelatine with a very high proportion of nitro-cotton. Stonite is a new variety of stone carbonite, containing less nitro-glycerine and more woodmeal to diminish the tendency to exudation. Ionite, or Cotton Powder No. 3, is a gun-cotton compound. Smokeless Powder is also a gun-cotton preparation for use in rifles. Flameless Securite is a mixture of nitrate of potassium, or ammonium, with metadinitro-benzole. There are also Ammonite, a new name for the miners' safety explosive, picric acid, and electric fuses and detonators. The number of factories for the manufacture of explosives increased by ten last year, bringing the total up to 122. The number of applications for new factory licenses received during the year was 15. The inspectors remark that the year was one of unusual activity. They report further, that, notwithstanding these new additions and extensions, the number of accidents shows no tendency to increase. On the contrary, so efficient are the rules and regulations imposed, and so careful are the manufacturers to comply with them, that accidents grow fewer year by year. The arrangements now adopted in every factory contrast very favorably with those existing previous to the Act of 1875.

Among the matters of special interest to the users of blasting explosives, are two which will at once arrest attention in reading the inspectors' report. The first is the statement that dynamite—that is, the ordinary kieselguhr dynamite—is being constantly and steadily driven out of use by blasting gelatine. In a few years it will have ceased to exist. The other is a matter of the highest importance, as it affects the safety of the miners. With a view to ascertain the relative sensitiveness of blasting gelatine in the frozen and the unfrozen state, the War Office Committee of Chemists on Explosives carried out an exhaustive series of experiments. The results showed that in the frozen state gelatine is very sensitive to blows. A 58 pound weight dropped from a height of 1 foot was sufficient to explode the substance, which in the unfrozen state required a fall of 12 feet to cause explosion. This is a matter of great practical importance, and it points to the origin of many accidents in ramming a charge of blasting gelatine. The difference was much less with gelatine dynamite ; unfrozen explosion occurred with a drop of from 7 feet to 8 feet, and frozen with a drop of from 6 feet to 7 feet. These figures, show, moreover, that blasting gelatine in the unfrozen state is much less sensitive to blows and friction than gelatine dynamite in the same state. It is only when frozen that the former appears to a disadvantage. The section of the inspectors' report which treats of these experiments is worthy of careful consideration by all who have the handling of explosives.

PEDESTAL DESIGNS FOR THE ROBERT E. LEE STATUE.

REFERRING to the competition for pedestal designs for the Robert E. Lee statue, noted in our last issue, Mr. D. Adler, chairman of the committee having the matter in charge, writes that the competition may be participated in by any draughtsman under 30 years of age, and who is not a practicing architect. Enough funds are at the disposal of the committee to enable them to award several bronze medals, in addition to the gold and silver medals already provided for.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

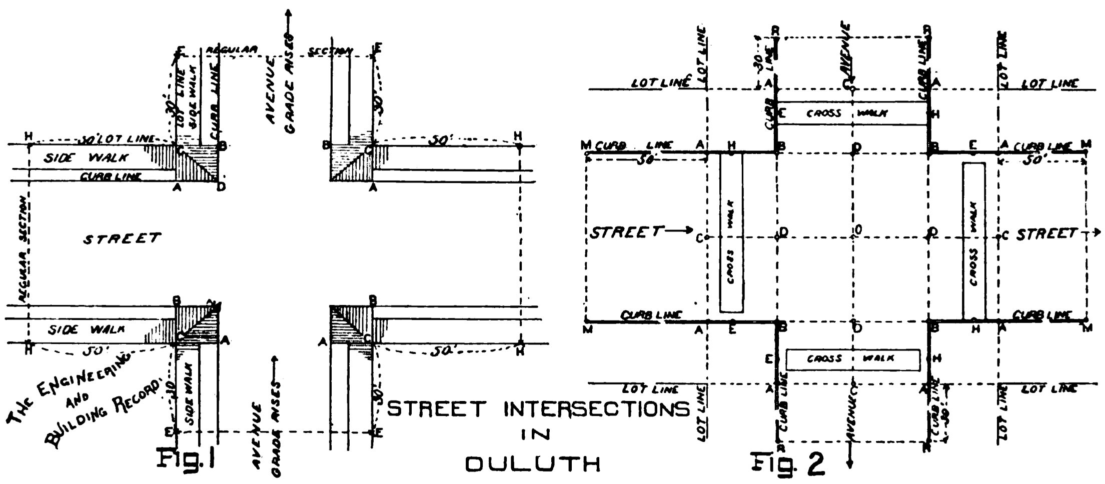
STREET INTERSECTIONS IN DULUTH.

OFFICE OF CITY ENGINEER,
DULUTH, MINN., August 13, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: Noticing your recent articles on grades at street intersections I inclose a blue print of our standard form for sidewalk and roadway intersection grades. These blue prints are furnished the overseer for the formation of each intersection after the curbs are set, the blank spaces being filled in with the appropriate figures for that particular intersection. My practice in establishing the grades for intersecting curbs is as follows : When grades exceed 8 per cent. the center grade of the street across intersecting streets is broken at a point opposite the block lines, and from this point to a point opposite the curb lines it is made 8 per cent. where it is again broken so as to be 3 per cent. across the roadway intersection. When less than 8 per cent., and more than 3 per cent., no break is made opposite the block lines, it being made only at a point opposite the curb lines. When 3 per cent. or less the grade is carried unbroken across the entire intersection. The above rule applies also to the intersecting street on the same intersection. The four curb intersections B B B B (Fig. 2), are in one and the same plane, established by the center grades of the intersecting streets. The street sections at M M and R R are made with opposite curbs level, and the curb grades R B and M B are laid to a straight line except when modified by a maximum grade of 8 per cent. at A B.

WILLIAM B. FULLER,
City Engineer.



STREET INTERSECTIONS IN DULUTH

Fig. 1   Fig. 2

[The blue prints referred to by our correspondent are reproduced in Figs. 1 and 2. On these blue prints are the following notes :

NOTES ON FIG. 1.

1. When the difference of elevation between A and B on the line A C B is more than ¼ inch to 1 foot, the top of the sidewalk at C must be at a point whose elevation shall be a proportional one between those of A and B on the line A C B.

2. When the difference of elevation between A and B on the line A C B is less than ¼ inch to 1 foot, the top of the sidewalk at C must be at a point whose elevation will give a rising slope from A to C of ¼ inch to one foot.

3. Break the grade at H and E from the regular section of the street and avenue and build the sidewalk on a straight (not curved) grade to C.

4. Sub-grade for all points on sidewalk is 8 inches lower than top of sidewalk.

NOTES ON FIG 2.

True Grade Notes.

1. Finished surfaces at C, D and O shall all touch a straight line drawn between the tops of the nearest curbs.

2. Finished surface of roadway at A C A and B D B shall crown on the arc of a circle from C and D to a point .... inches below top of curb at A, and .... inches below top of curb at B, respectively.

3. Finished surface of crosswalks H E shall be on a straight line from curb to curb, and .... feet in width; then to slope gradually on each side to a line .... feet distant, where it shall conform to the sections A C A and B D B, respectively.

4. From the regular section of the street at M M curbs and roadway shall be built to a straight grade to section at A C A.

5. From the regular section of the avenue at R R, curbs and roadway shall be built to a straight grade to section at A C A.

Sub-Grade Notes.

1. Sub-grade at C shall be .... inches below finished surface at C.

2. Sub-grade at O shall be .... inches below finished grade at O.

3. Sub-grade section at A C A and B D B shall slope from C and D to a point .... inches below top of curb at A, and .... inches below top of curb at B, respectively.

4. For the width and length of the crosswalks the subgrade shall be .... inches below true grade of same, then to slope gradually on each side to a line .... feet distant, where it shall conform to the sections of sub-grade at A C A and B D B, respectively.

5. Abutments shall be put in at ends of crosswalks E and H, where necessary to allow water to pass, or as directed by the engineer, so as to allow .... inches in clear width for gutter, whose surface shall be .... inches below top of curb.]

THE Commissioners for the London Exhibition of 1851 have come to the conclusion that in order to utilize the balance of money in hand it would be advisable to institute a series of £150 a year scholarships for science students, tenable for two years, with a possible extension of one year at the pleasure of the Commissioners.

THIRTY-TWO years ago the first signals were sent through the Atlantic cable from shore to shore,

INFLUENCE OF SEA WATER ON PORTLAND CEMENT.

CONCERNING the influence of sea water on Portland cement, M. E. Candlot, according to the London *Engineer*, says: "The nature and quantity of the water used are of influence on the setting of cement. Sea water, by forming calcium chloride and sulphate by double decomposition of the magnesium salts it contains with the lime compounds present in the cement, retards the setting. Neat cement gauged with sea water is at first stronger than when fresh water is used, but retrogrades after some months. Cement, when made up into mortar by admixture with sand, shows no such tendency; the use of sea water may delay its reaching its full strength, but this is attained after the lapse of a year. This fact applies particularly to finely ground samples."

THE FRANKFORT ELECTRICAL EXHIBITION.

THE General Electrical Company of Berlin and the Oerlikon Engineering Work intend applying as motive power for their exhibits at the Frankfort Electrical Exhibition, next year, a water power of 300 electrical horsepower, transmitted from Laufen, on the Neckar, to Frankfort, a distance of about 109 miles, through a copper wire 5 millimeters in diameter. The object is to prove, experimentally, the practical possibility of supplying a large area, or even a whole province, with power and light from a single central station.

ARRANGEMENTS have been made in India, by the Forest Department of the Mysore State, for maintaining fuel plantations on a large scale for railroad supply.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department*. Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

BUILDING INSPECTION.

W. D. CLARK, of Springfield, Mass., writes: "I must trespass upon your indulgence by expressing my pleasure in reading the discussions upon the subject of building construction and building inspection, and hope the discussions will continue. Brooklyn truthfully wrote that 'the subject of building inspection is a very serious one.'

"I am glad to know that within the past six or eight years there has been marked advancement in skill and scientific ability among architects of our country. Still there is room for improvement, and such letters as those written by Civil Engineer and Brooklyn will arouse public sentiment that will bring about a very much needed reform in the construction of private as well as public works.

"What is needed most is that public sentiment be enlisted in sustaining honest, reliable engineers, architects and superintendents, in the discharge of their duties. Dishonest contractors will not submit to having an honest, competent superintendent about their works, and will resort to every strategy possible to embarrass, annoy and drive them from their job, and I reiterate my hope that in the near future, integrity, skill and faithfulness will be recognized more than it has been within the past thirty years."

PURIFICATION OF WATER.

ALFRED SPEER, Passaic, N. J., writes: "Will you be kind enough to tell me of any work treating upon the cleansing of water used by factories, so that it may re-enter the stream clear?"

[The subject has been treated at some length in the columns of THE ENGINEERING AND BUILDING RECORD, and has also been investigated by the Massachusetts State Board of Health. Nichols on "Purity of Water Supplies" will be found to give some valuable information on the subject.]

HOW MANY LEAKS ARE ALLOWED IN AMERICAN WATER MAINS.

WILLIAM PERRY, JR, hydraulic engineer, Montreal, Can., writes: "Your valuable journal of August 23 is at hand. I am pleased to see the matter of leaks in water pipes receive the attention of such competent engineers and superintendents as Edwin Darling, of the Pawtucket W. W., R. I.; W. L. Cameron, of Memphis, Tenn.; G. H. Benzenberg, City Engineer of Milwaukee, Wis., and L. H. Gardner, of the New Orleans, La., Water-Works. Mr. Gardner says: 'I doubt if your correspondent is serious in his question.' I inclose you the complete letter, and if you would kindly insert the part referred to, you would be in a position to vouch for its genuineness."

[The letter referred to by Mr. Perry is in the shape of a clipping from the Montreal *Gazette*, to which it was sent as a reply to an earlier letter by Emile Vanier, Chief Engineer Lachine Water-Works, the latter being the works under consideration. The portion of the letter to which particular attention is directed, reads as follows:

"Now, as far as the joints are concerned, I will state that there were, on an average, four leaks per mile, all in the contractor's work. However, this is not at all excessive, for American water-works contractors always figure on seven per mile; this, I think, tends to prove that 'Lachine' absolutely knows nothing at all about the joints when he states that they were a 'disgraceful piece of work.'"]

AN electric street railroad, about one mile long, was recently inaugurated at Bremen, Germany. The line is the first to be carried out in Europe on the Thomson-Houston system.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

THE RELATION OF HOT-WATER BOILER HEATING AND RADIATOR SURFACE.

J. L. BROOKS, of Dayton, O., writes: "I cannot find in Baldwin's book on 'Hot-Water Heating and Fitting,' any data for the amount of heating surface required in a boiler. In some instances the author gives 1 to 49, in another 1 to 7, etc. Will you please give me what you consider about the proper and correct amount for ordinary conditions. Please state whether you consider the locomotive style of boiler a good one for hot-water heating if prepared as Baldwin recommends the horizontal boiler to be."

[There can be no fixed rule for determining the proportion of boiler to radiator surface for a hot-water apparatus. What you can determine is the amount of grate surface necessary to do a certain duty. Then you can proportion your boiler to your grate. Let us assume that we have 1,000 square feet of hot-water radiators, and that the average duty per square foot in warming air is 220 heat units per hour, and that the total duty will be 220,000 heat units. This is the equivalent of 210 pounds of water evaporated to steam, and for this you must burn from 21 to 28 pounds of coal per hour.

In a heating boiler from 4 to 6 pounds of coal per hour per square foot of grate is reasonable; therefore you must have a grate of from 5 to 6 square feet for your boiler when you have a fair draught, and a larger one with poor draught. If you use a small tube locomotive boiler you require between 25 and 30 square feet surface for each square foot grate, and with large tubes from 20 to 25 of boiler to one of grate, so that your boiler surface for 1,000 square feet of radiation will be about from 100 to 150 for locomotive boiler and the same for horizontal tubular. With some very plain boilers, cylindrical or upright, nearly all fire box, from 1 to 10, and even less, is often ample, and with pipe boilers you may require as much as 1 to 40.

Your experiences and discretion must serve you between those points. Ordinarily 1 of boiler to 10 of radiator will do with horizontal tubular locomotive boilers.]

PLUMBING IN A KANSAS CITY RESIDENCE.

THOMAS HENDERSON, Dallas, Tex., writes: "In your issue of August 23, page 187, 'T. H. S.' gives a sketch of a Kansas City job of plumbing, and asks for opinions as to its merits. I beg to offer the following:

"*First.*—In the first place, a system that requires an artificial means to promote circulation of air in vent pipe is defective.

"*Second.*—The steam coil to work in this case ought to be above tee.

"*Third.*—The local vent from grease trap will fill up at bottom by condensation.

"*Fourth.*—All local vents ought to enter flue above fixtures.

"*Fifth.*—The soil pipe C ought to be extended through the roof separately.

"*Sixth.*—The waste from basin on third floor ought to be connected to waste between bath-tub trap and soil pipe.

"*Seventh.*—The horizontal vents ought to have a fall towards the fixtures.

"*Eighth.*—The whole system of soil and vent pipes is very badly arranged."

J. W. HUGHES, Montreal, Can., writes: "The illustration of plumbing in a Kansas city residence, sent you by 'T. H. S.,' and published in your issue of August 23, is interesting as being different from prevailing practice, but in looking it over the 'why' test comes to mind. I would like information from your correspondent on the following points: Why is a steam coil necessary? Why is it a good thing in a dwelling? Do they have steam all the year round, or only in winter? If only in winter, what heats the ventilating stack in summer, the only time when steam or artificial heat would be required in such a stack? Why are the back air vents run from the upper floors down to the basement? What advantage is gained from so doing to offset the additional cost, also the additional friction entailed in such long runs, and increased number of ells? Why are the back air vents run up several feet before they turn down, and not started down at once on leaving the trap? Why is soil pipe C M D run across, under floors to soil-pipe B, instead of being carried direct through roof, which, if the drawing is correct, would have been the cheapest, easiest, most direct and best working plan? Why are the back air vents V carried back and forth and apparently mixed up and made as complicated as possible? Why would it not have been better to run a separate line of back air vents down alongside each stack of soil-pipe, branching the adjacent fixtures into it, if it was really necessary to run it down at all? Why, if the fresh-air inlet is necessary, is the pipe C run from it and connected to E? Will this pipe C not seriously affect the efficiency of the fresh air inlet? Why would it not have been better in every way to have omitted the vent stack A, run the lines of soil pipe, suitably enlarged, direct through roof, and connected the back air vents into it above the highest fixtures?

"The plan as shown doubtless possesses merit in the eyes of the man who designed it, and he has, doubtless, good and sufficient reasons for adopting it, and my desire in writing is to have the benefits, if my worthy confrère will explain the advantages of his system."

J. TUCKER, of Boston, writes: "Assuming that the drawing which is shown on page 187, in your issue of August 23, correctly shows the way the vent and soil pipes run in the Kansas City residence, and noticing the comments of your correspondent, T. H. S., I would like to ask him what the object was in deviating from the standard practice of carrying the vent pipes directly up, either through the roof, or into the main soil pipe stack above the highest fixture. As shown, it seems to me that a needless expense has been incurred in running the vent pipes down, and the bends in those pipes will restrict the movement of air. In the summer months it is not likely that there will be steam in the coil on the pipe A. This is certainly inferior to the regular method of carrying vent pipes as has been so often advocated in your columns."

BOOK NOTICES.

POOR'S HAND BOOK OF INVESTMENT SECURITIES. A supplement to "Poor's Manual of Railroads." H. V. and H. W. Poor, publishers Price, paper cover, $1 50; cloth, $2.50.

In the editions for 1886, 1887, and 1888 of "Poor's Railroad Manual" were given tables showing the range of stock and bond values at the leading exchanges in the country for a series of years. In the 1889 edition of the manual this information was omitted, in consequence of the great increase in the size of the volume. It has, however, now been issued separately, forming a valuable reference book for bankers, brokers, investors, and all others who may be interested in railroad and other investment securities. It contains a table showing the range of values at the leading stock exchanges of the country during the 12½ years from January 1, 1878, to June 30, 1890; a statement of all dividends paid by the railroad companies of the United States during the past eight year; a list of bond coupons, payable each month in the year, with the places where they are payable; a statement of the stocks and bonds listed on the New York Stock Exchange during the past 11½ years, January 1, 1879, to June 30, 1890; a statement showing for the leading railroad companies (*a*) close of fiscal year; (*b*) time of holding annual meeting; (*c*) closing and opening of books; (*d*) place of holding annual meeting, etc., etc.; a statement showing, by cities, the location of all railroad general and transfer offices.

MANUAL OF AMERICAN WATRR-WORKS, 1889-90. Published by the *Engineering News* Publishing Company, New York.

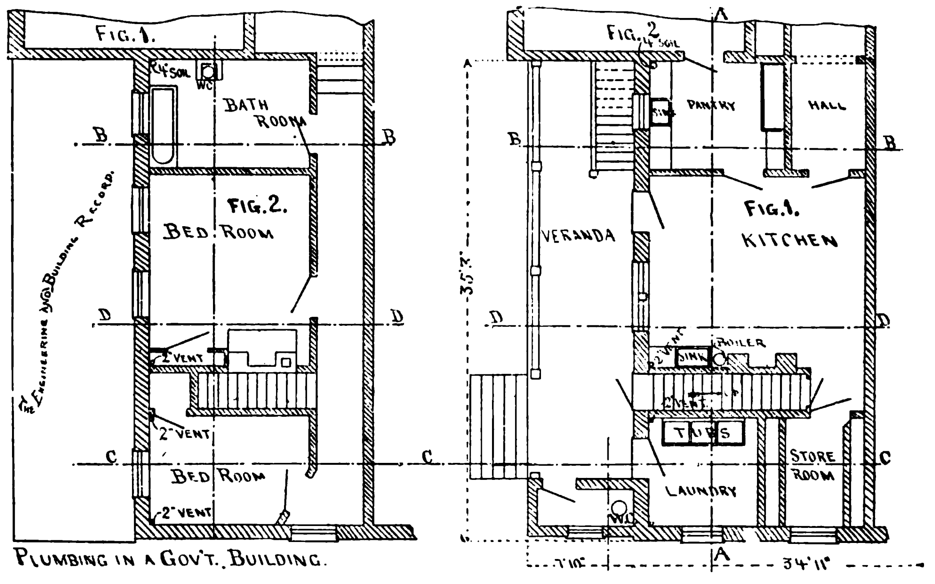
The general character of the "Manual of American Water-Works" has become so well known that it is not necessary to enter into it in detail. Briefly stated, it gives the history, list of officers, particulars of construction, source and manner of water supply, pumping machinery, etc., of the different water-works in the United States and Canada, and thus forms, as can readily be understood, a most valuable reference volume for all interested in the subject. As might have been expected, the work has grown since its previous edition, the descriptions of works and the data generally having been added to considerably. In several cases illustrations are given of dams and reservoirs, constituting features of special interest. The concluding pages of this volume are given up to family and meter water rates in various cities.

DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

CRITICISM ON PROPOSED PLUMBING IN A GOVERNMENT BUILDING INVITED.

Figures 1 to 7, inclusive, show the plumbing in a Government building, and are prepared from drawings sent by Assistant Quartermaster Captain J. W. Jacobs, U. S. A., with a request for technical criticism of the system.

Figures 1 and 2 are first and second floor plans, respectively. Figures 3, 4, 5, 6 and 7 are sections at A A, C C, D D, E E, and B B, respectively.



PLUMBING IN A GOV'T. BUILDING.

FIG. 7.

FIG. 6.

PLUMBING IN A GOVERNMENT BUILDING

THE ENGINEERING AND BUILDING RECORD

Figures 7′, 8 and 9 show the modifications herein suggested. The plans indicate a dwelling house, but nothing is stated as to its surroundings; presumably it is a detached building at some military post. With the evidence before us, the following criticisms suggest themselves.

An unnecessary amount of piping seems to be provided for. The offset, at roof, of the main soil-pipe is not desirable; if it is made to avoid windows in neighboring building it is not far enough away, if neighboring windows overlook it the pipe should be carried up the neighboring wall above the main roof. If no windows overlook the pipe, it will shorten the main line in the cellar to carry the main soil pipe up along the opposite partition, as shown in Fig. 7′. This allows a clean-out in the cellar, at the end of the main drain, which can be readily worked with clearing rods or wire.

Instead of hanging the main drain from the cellar rafters build 8x8 inch brick piers under each vertical column, and spike the pipe to the side wall with pipe hooks at frequent intervals.

If practicable place the main house trap inside the house and extend the fresh air inlet well away from the house and turn it up 18 inches above ground with ¼ lead and brass grating.

The present arrangement is good if the line to the trap is not too long and foul, in which case it will be vented through the house. If retained, as shown in Fig. 3, the vault cover should be freely ventilated, and protected from snow, and the cover should be shifted so that dirt may not fall through the grating into the open end of the fresh air inlet pipe. The choice of arrangement would depend on local conditions.

Do away with the 2-inch back vent riser from the kitchen sink, and carry the sink back vent across under the stairs and connect with the back vent to the laundry sink. In the same way do away with the 2-inch vent riser from the hopper closet and connect with laundry to column, as shown in Fig. 7′ and 8. This reduces the amount of piping and is equally efficient.

The hopper water closet on first floor has no flush tank shown. It should be provided with one placed on the laundry wall to protect it from frost, as shown in Figs. 7′ and 8.

Instead of the plunger closet on second floor bath room use a washout, short hopper or syphon closet.

Increase all vertical columns one inch in diameter at the roof, and protect open ends with wire globe cages.

Use only tested, extra heavy pipe with deeply-leaded joints, and after all work is finished except setting up of fixtures, test the complete system of drain and vent pipes with water or air pressure from beyond the house trap to the level of the open ends of the pipe above the roof. Have this done *after* lead traps and lead closet connections are in. After the fixtures are set and the work completed test with peppermint or smoke machine.

Use only brass ferrule screw-cover cleanouts.

Use only heavy lead pipe, and in short lengths. Carry the iron pipe-work as close to the fixtures as possible.

Fig. 7′ is a section through the house, as modified; Fig. 8 is a section at Y Y, and Fig. 9 is a section at X X, Fig. 7′. Fig. 10 shows a more desirable alternative arrangement for the laundry and kitchen, the main vent pipe A being here carried across on to the laundry wall.

Any further comments by our readers we shall be glad to publish.

HEATING AND VENTILATING SCHOOL-HOUSES.

(Continued from page 204.)

Prof. S. H. Woodbridge's paper was devoted to the application of furnaces to the heating of small school-houses.

The thing which is desirable to accomplish in the heating of a school-house is to secure an effective circulation of a large volume of air at a comparatively low temperature. The two important requirements in a furnace for heating a school-house are, first, that the furnace shall have a large heating surface, and, second, that such surface, heated to only a comparatively low temperature, shall evenly warm large volumes of air moving over it. It is necessary to have a special type of furnace in order to do this work. The ordinary furnaces are quite inadequate to such work.

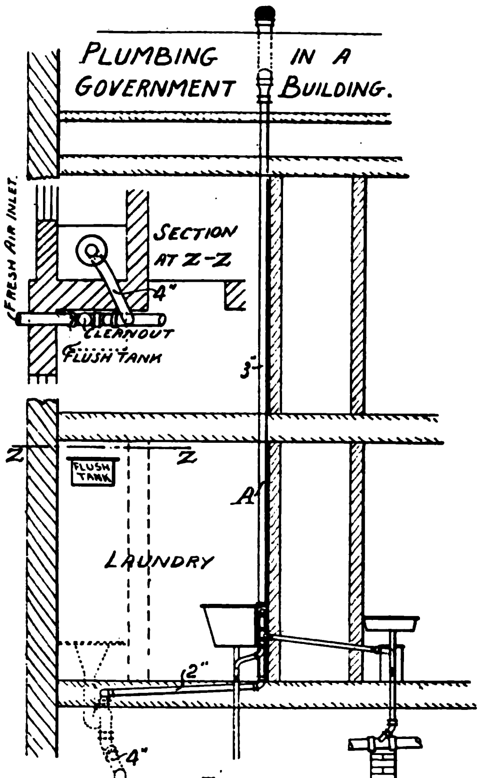

FIG. 10

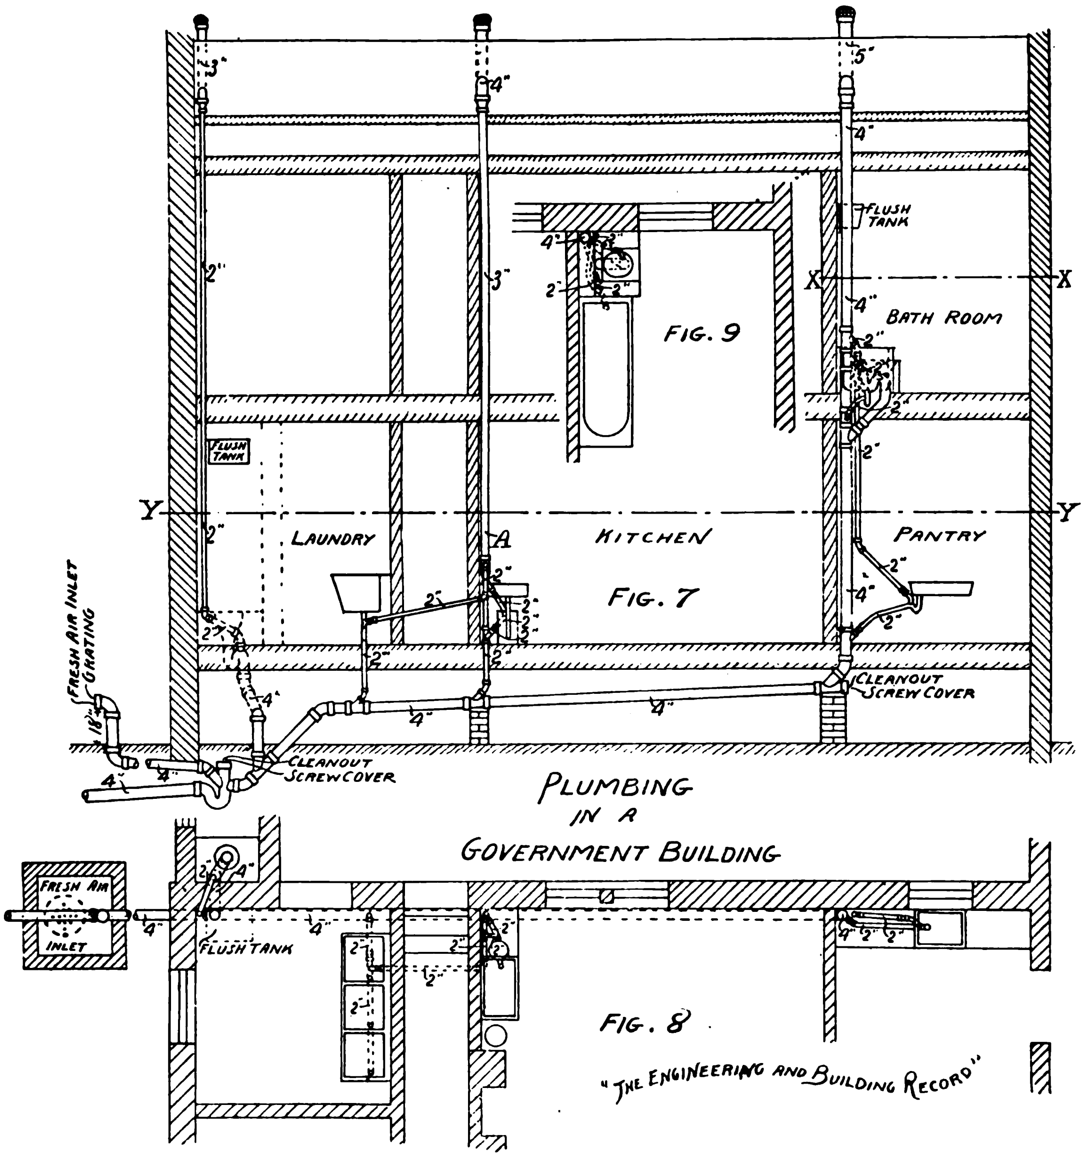
We have as a usual thing, for instance, a cylindrical furnace standing within a case through which the air passes, ultimately finding vent through conductors to different parts of the building. We have here a comparatively small space, according to the distance between the furnace shell and the outside casing; we have a considerable vertical extension of furnace, that is, the air passing in at the bottom becomes more or less heated by contact with the lower part of the furnace, and in passing upward over that surface it grows hotter and hotter as it ascends to the top, until, when it reaches this point, it has a temperature of from 200 to 250, or even as high as 300 degrees. In this case the general extension of the furnace surface is vertical, the air being heated as, in relatively small quantities, it moves upward continuously against that surface. Furthermore, the heating surface, as compared with the grate area in a furnace well proportioned for ventilating work, is large. In the ordinary furnaces this is not found to be the case. The heating surface may be itself 20 times the area of the grate, but Professor Woodbridge thinks it is exceptional when we get as high as 30 or 40 times the area of the grate. What is wanted, then, in order to perform the work of heating and ventilating is a large heating surface in comparison with the area of the grate.

In the case of steam heating, radiators may have from 150 to 300 times the area of the fire grate, but in the ordinary furnace 40 times the area of the grate in heating surface is exceptionally high. What is wanted is a furnace with a large surface and relatively great horizontal extension instead of a small surface with vertical extension. If we could take, for instance, that cylindrical furnace, 3 feet in diameter and 6 feet high, and turn it over on its side, we should have a large area about the furnace through which the air could move, as compared with that of the annular ring in an ordinary furnace of vertical extension. Taking the other section of it for a horizontal extension of the same furnace, we should have a space for air movement of the same width as before, but of a length equal to the horizontal perimeter.

A large horizontal extension, rather than a vertical extension, is required for two reasons. In the first place, in order to get a greater area through which the air may move, and, in the second place, in order that the air may not be heated to too high a degree, as is the case with the furnace of vertical extension. When the air has reached the top of this furnace with longitudinal extension its temperature may be 150 degrees as against that of 300 degrees in a furnace of vertical extension.



PLUMBING IN A GOVERNMENT BUILDING

There are other things to be desired in the working and construction of a good furnace. The combustion should be good. The fire pot should not be too deep. The fire should be fairly shallow; there should be an intimacy of contact between the hot combustion gases on the inside and the air on the outside. The shell is the medium that transfers the heat of the combustion gases to the air on the outside; the air on the outside has to be heated, and the gases on the inside have to give up their heat.

Among the furnaces that best fulfill these several conditions, Professor Woodbridge places first, the Smead, because of the wider familiarity with it. In this furnace there is intimacy of contact between the combustion gases on the inside and the air on the outside, and a pretty complete transfer of heat is effected. The fires are shallow—the provision for complete combustion is good, and the area of the heating surface is large as compared with that of the grate. There are also the Fuller & Warren furnace and the Mahony furnace, worthy of mention as furnaces of the better type for ventilation work. But they are all connected with some system of ventilation, and the call comes for some furnace which is independent of any such system.

Professor Woodbridge then called attention to a furnace which is as old, in point of invention and manufacture, as any of those just mentioned. It is known as the "Gold Hygeian Heater." The general form is similar to that of a locomotive boiler. The body of the furnace (see Fig. 5) is in box form with arch top, and contains a fairly shallow fire-box and large combustion chamber. The cylindrical part of this furnace may be extended almost indefinitely by means of rings attached to the body of the furnace, and to each other by bolts. We have in this furnace a horizontal, rather than a vertical extension of surface. Beyond this, we have upon the body of the furnace itself and upon the extension rings, rigidly attached to them as one piece with them, cast-iron flanges, and attached to these flanges are spurs or pins, which greatly extend the surface of the heater. The heating surface is, therefore, so large in proportion to that of the grate that it cannot have a very high temperature.

The fire pot is lined with brick, so that that part of the furnace cannot be highly heated, or it cannot be heated to anything like a red heat.

The external surface is about eight times the internal, and the area of the exterior surface is about 100 times the area of the grate. This ratio may be made much larger by extending the cylindrical part of the furnace. The rings making up this part are very carefully put together, sleeving closely one into the other; and they are drawn and held together tightly by short bolts, so that it is practically a very tight furnace, and it is not especially liable to breakage by warping. There is one objection, and that is in the unequal heating of the shell and the flanges, tending to breakage, but that danger has been avoided by making the flanges of corrugated form rather than of more rigid plane form.

For completeness of combustion, which is always desirable, the furnace has a large combustion chamber, and the gases in rising from the coal have a chance to mingle and to complete the combustion before coming into contact with the cool surfaces of the furnace. There is, furthermore, a very finely perforated plate in front admitting air, which, on striking upon and passing over the fire, becomes heated, so that it is quite common to see, in the rear and upper part of the furnace, the blue flame characteristic of the burning of carbonic oxide gas.

Professor Woodbridge would not rely upon such a furnace as this to heat a larger space nor a greater air volume than would be required by 100 scholars, though it would provide liberally for what would be required by that number. As to the matter of applying this furnace to the heating of small school houses, Professor Woodbridge submitted several sketches. The general plan of the furnace and the proposed methods of encasing it are shown in Figs. 6 and 7. In regard to the furnace itself, it will be noticed that the smoke vent is so placed as to take the cooler gases from the combustion chamber. The furnace is placed in a case, seen to better advantage in Fig. 7. The cold air passes into the heating chamber through a large aperture 4 feet by 18 inches, at the lower part of the rear wall of the casing, passing up by the pin-covered flanges and becoming mildly heated as it reaches the upper part of the chamber.

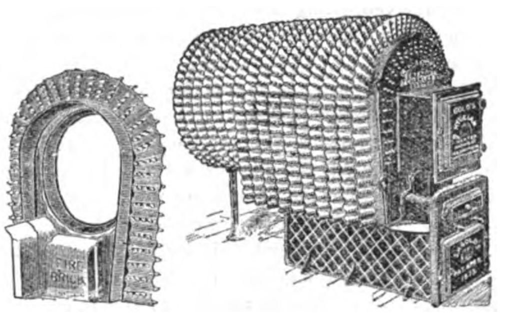


Fig. 5

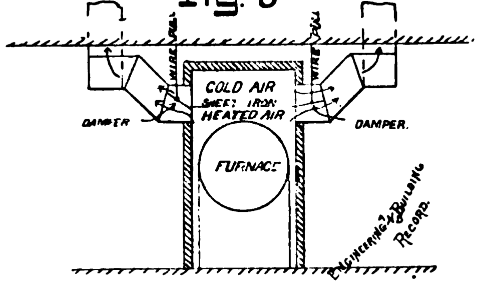

Fig 6

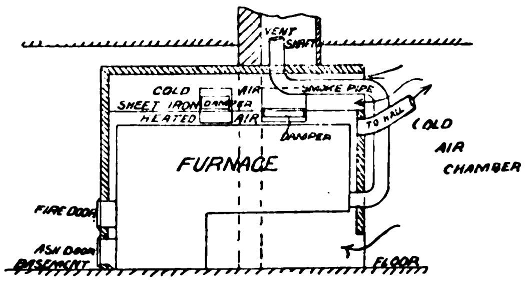

Fig. 7.

HEATING AND VENTILATING SCHOOL HOUSES

If several rooms are to be heated from one hot-air source, provision must be made for giving different or required temperature to the air distributed from that source. Sometimes it is required to heat one room to a certain temperature and another room to a different temperature. If only one room is to be heated, the fire may be regulated so as to produce the temperature required; if several rooms are to be heated, the fire must be regulated so as to produce the temperature required in the room most difficult to heat. The furnace temperature must be governed by the requirement of the room demanding the highest temperature of air supply, and some ready and effective means must be employed for reducing that temperature, but not the volume of air supply to other rooms.

In the lower part of the furnace is, as usual, the cold-air box terminal, but in this plan we have another cold-air chamber on the top of the furnace as well. Such an arrangement has the advantage that the top or any part of a furnace in close proximity to wood work is kept cool. This method affords an effective means of keeping the upper part of the furnace perfectly cool, so that when the furnace has been heated to its hottest the top will feel cool to the touch, for, the colder the weather and the hotter the fire, the cooler will this top be. But, further than that, it provides for cold air to be mixed with the heated air for distribution to the different rooms. The heated air and the cold air are separated by a diaphragm, and their passage into the supply conduits allowed or checked by the movement of a valve, which controls the quantities of each which may pass and mix beyond it. In the left-hand conduit the valve is shown in a position to allow the heated air to pass freely and to hold the cold in check. The right-hand valve shows a more equal movement, resulting in lower temperature of supply.

Flues of such size should be provided that the full quantity of air shall be supplied with the smallest difference of temperature between the air inside of the supply flue and the outside air, under which the system is to furnish required ventilation. The flues must be of such capacity as to supply and remove the required air volume when the outside temperature is just too cool to open windows. If we attempt to use such flues in cold weather without throttling them, the quantity of air moved through the furnace will be altogether too great to be heated, and greatly in excess of requirement. The most air is needed in the warmest weather, and the least air in the coldest weather. There should, then, be provided some means by which the ventilating flues can be reduced according to the increased difference between the inside and outside temperatures.

In Fig. 6 is shown the means for such regulation of flue area in the supply system. The sum of the hot and the cold-air apertures from the furnace to the conduits to which they belong is equal to the area of the conduits. The hot-air apertures are in area one-third, and the cold air are two-thirds that of the connected conduits. If the weather is cold not much cold air is needed, and by simply drawing up a damper by means of a wire and chain, the effective area is reduced to one-third of the total area available and required in mild weather, and shown in the right-hand conduit.

(TO BE CONTINUED.)

REMOVAL OF MINE GAS BY EXHAUSTION.*

EXPERIMENTS on the removal of mine gas by exhaustion were carried out a number of years at the King's Mine at Grenenberg, near Aachen, Germany.

The removal of the gas was effected by a disused compressor which, by an alteration of the valves, was made to do duty as an exhauster. From the compressor a main pipe of 3¾ inches diameter was carried down the pit and for a distance of about 1,300 yards, when secondary pipes of 2 inches were placed for about 300 yards in the main levels. Finally smaller pipes, of 1-inch bore and terminated by plate suction-roses, were extended into the front of the headings, and kept to the top of the level by clamps attached to the timbering. The roses were at first made of tin-plate perforated with fine holes on both sides, but these were found to admit too much air on the under side, especially in a weak gas current, so that ultimately the under side was closed and the perforations on the top surface were correspondingly enlarged. In places where the dip of the seam was comparatively low, the roses were made of a long rectangular form and covered with wire gauze like that used in safety lamps. Vacuum gauges were inserted at different points in the tubes to measure the effective rate of exhaustion. For a short time a Körting steam-jet exhauster was tried, but it did not prove equal to the work. The flow of the exhausted gases was regulated by a double-bell gasholder, so arranged that while one bell was being filled the other was delivering. This, however, did not work satisfactorily and was abandoned, the gases being forced directly by the pump into the delivery pipe. Several small gasometers were used for collecting gas for experimental purposes and testing, the latter being done every twelve hours.

The experiments as a whole proved a decided failure, on account of the fluctuation in the composition of the gas, which sometimes contained as much as 10 per cent. of firedamp and sometimes none, the variations taking place without any apparent cause.

The continued attention required in extending and varying the position and area of the suction passages was also very considerable, and such as to cause considerable hindrance in the levels when the driving was actively carried on.

The gas was applied to the firing of two boilers, a row of jets being introduced below the firebars from a tube which was connected with the main by a safely U tube sealed with water, and at all the joints of the pipes wire gauze diaphragms similar to those used in safety-lamps were inserted.

The boilers were experimented on for some time, but neither a more active evaporation nor any saving in fuel was obtained. The gas was also tried with the magnesia comb burner of Fahnjehelm, but only the lower third of the bars could be brought to the proper degree of incandescence. The third suggested application of the gas—namely, for driving gas-engines, was not tried.

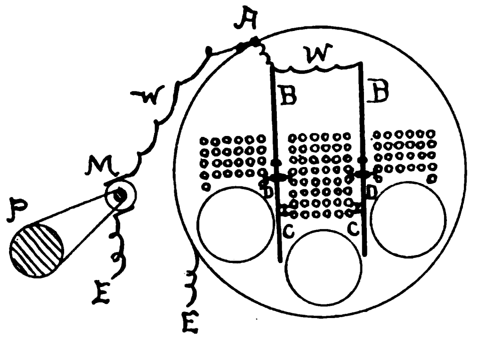
A DYNAMO FOR THE PREVENTION OF BOILER INCRUSTATION AND CORROSION.

IN discussing a paper on "Water-Tube Steam Boilers," recently read before the British Institution of Civil Engineers, E. R. Dolby referred to the use of primary batteries to pass electric currents through boilers to get rid of incrustation, and described an arrangement supposed to have some advantages over that. The disadvantages in the use of galvanic batteries were stated to be that it was difficult with them to keep up a continuous electric current for any length of time; that the zinc rapidly wore out, and that, especially in hot climates, the solution required continual attention.

The system described by Mr. Dolby, is shown diagrammatically in the annexed illustration, which represents a marine boiler fitted up. The apparatus itself is shown by heavy lines. The propeller shaft is marked P. A small dynamo M is driven by this shaft through a belt. Two brushes are shown. From the upper brush is led a wire W to a point A in the outside shell, through which it is carried, being insulated from the shell itself. The wire then enters the boiler and is fastened to two rods B B above the water line. These rods are fastened below at about the center of the height of the tubes to two plates C C, which are held in position by cramp and bolts D D. The cramps are fixed to the tubes and are screwed up so as to wedge the plates in position, but they are insulated from the plates themselves. The small dynomo is an alternating machine, and the current, supposing the upper brush to be at first positive, will pass by the wire outside, enter the boiler, and from the two electrodes C C will pass through the water to the shell, from the shell by the short wire to earth, and back again to the other brush. When the next alternation comes, the current will pass by earth to the shell, and from the shell through the water to the plates. The effect of the alternation was believed to be that as the current passed through the water it would electralize a small part; the hydrogen, acting as a metal, would follow the course of the current, and would be deposited on the shell and flue tubes. With the change of current, oxygen would be produced on the same surfaces. The two would combine and form a thin film of chemically pure water which would prevent deposit upon the surfaces. The throbbing caused by the current alternations would also loosen any side already adhering. The apparatus is covered by several English patents. The insulator through the shell is woodite, and there are two washers of asbestos drawn together by nuts. The insulators inside might be of porcelain. The system is applicable also to land boilers.



DYNAMO for PREVENTING BOILER SCALE

AN INCLINED TURN-TABLE DRAWBRIDGE.

THE Adams Street drawbridge over the Chicago River is 257 feet long, with a central turn-table, and has three trusses, 21 feet to centers, giving a double roadway. The street grades on either side compelled a difference of level between the approaches of over two feet, and in order to accommodate this difference and, at the same time, have the bridge reversible so that it could follow a passing vessel around and thus avoid loss of time in swinging back, City Engineer William R. Northway tipped the bridge, turn-table and all, up on an inclination of 1 in 120, thus accomplishing the desired result in a simple and satisfactory manner.

THE National Library in Paris is the largest in the world. It contains 2,500,000 volumes.

TUNNELING ON THE COLORADO MIDLAND RAILROAD.

ACCORDING to the Louisville, Ky., *Courier Journal*, a piece of railroad tunneling of more than common interest is about to be undertaken by the Colorado Midland Railway Company. After leaving Leadville, which is at an elevation of 10,025 feet, the road runs around the mountains at a distance of 12 miles, reaching Busk at a height of 10,000 feet. From this point the road zigzags up the face of the mountains for a distance of five miles to reach a point 500 feet above Busk. On this part of the trip long lines of snowsheds are erected to protect the track, and in these drifted snow lies the year round. The old tunnel here pierces the continental divide at an elevation of 11,528 feet, which is within 30 feet of the height of the Alpine pass, on the Union Pacific road, the highest in Colorado. This tunnel is about 3,000 feet long. It is proposed to begin the new tunnel at Busk. Its length will be 9,350 feet, and the highest point reached will be the 10.948.7 feet. The maximum grade on the old line is 3 per cent., and the new is only 1.4 per cent. The length of new line required is 3.25 miles, and this replaces 10.18 miles of old line, effecting a saving of 6 93 miles. The section of the tunnel is 15 feet wide and 21½ feet high. Work was to have been commenced on August 1, and it is expected that 20 months will be needed to finish the contract.

HYDRAULIC RAMS.

ACCORDING to a paper on "Hydraulic Rams," read some months ago by Jay M. Whitham before the Arkansas Society of Engineers, Architects and Surveyors. Eytelwein seems to have been the first to investigate the mathematical theory of the ram. His experiments led him to the following formula in which

Q — cubic feet of water descending in one second through the drive pipe

q — cubic feet of water discharged in one second through the delivery pipe ;

H — fall in feet of Q;

h — rise of feet in q.

The rise, h, is the measure of the friction and static head against which q must be delivered. Then—

Diameter of the drive pipe in feet — $\sqrt{1.63\,Q}$;

Length of the drive pipe in feet — $H + h + \frac{{}^{2}h}{H}$;

Volume of air chamber — volume of the drive pipe.

The efficiency of the ram, that is, the ratio of the work done to the work expended, is *when h does not exceed 20 H,*

$$\frac{q\,h}{H\,(Q-q)} — 1.12 - 0.2\sqrt{\frac{h}{H}}.$$

and when h does not exceed 12 H, the efficiency is

$$\frac{10\,H}{10\,H+h}$$

The sizes of simple rams are given in the following table (when the discharge pipe is more than 1,200 feet long, use next larger size pipe):

Quantity of water furnished per minute by the spring or brook to which the ram is adapted.	Length of Drive Pipe.	Caliber of Pipes.	
		Drive.	Discharge.
½ gallon to 2 gallons per minute...	25 to 40 ft.	¾ in.	⅜ in.
1 gallon to 4 gallons per minute...	25 to 40 ft.	1 in	⅜ in.
2 gallons to 8 gallons per minute. .	25 to 40 ft.	1½ in	½ in.
3 gallons to 14 gallons per minute...	25 to 40 ft.	2 in.	1 in.
4 gallons to 25 gallons per minute...	30 to 40 ft.	2½ in	1¼ in.
8 gallons to 60 gallons per minute...	30 to 40 ft.	4 in.	2 in.
12 gallons to 120 gallons per minute...	30 to 50 ft.	6 in.	2½ in.
80 gallons to 250 gallons per minute...	30 to 50 ft.	9 in.	3½ in.

In order to operate these rams successfully the following rules must be observed—viz.:

The drive pipe must be from 25 to 50 feet long, so as to have the necessary uniformity in the flow of water through it. Where space is not available for such a length, a coil may be inserted in the drive-pipe aggregating the entire length. If a coil is used its radius should not be less than 2½ feet.

The fall of water, H, should be 18 inches or more. The capacity of the ram increases with the fall.

Water may be carried through a discharge pipe half a mile long, or raised through an elevation of 200 or more feet. A fall of 10 feet will raise water through 150 feet, yet as the elevation increases the quantity discharged decreases, other factors being constant. If the discharge and elevation are all that are required there is no advantage gained in having the fall, or the quantity flowing through the drive pipe greater than is necessary, for then the strain on the ram is not uselessly increased.

A safe rule in estimating for a ram where the discharge pipe is from 800 to 1,000 feet long is that Q = from 10 to 14 q, and H = 10 H; or, what is the same, Q = from 5 to 7 q when h = 5 H.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

For works for which proposals are requested see also the "Proposal Columns,' pages i-ii-223.

WATER.

For Additional Water Items see Proposal Columns.

RITZVILLE, WASH.—There is a movement among the local officials to investigate the water-works question, and just now it seems likely that a plant will be established in the near future.

CHAMBERSBURG, PA.—The report of Engineer John Birkinbine in favor of taking an additional supply of water from Gish's Dam has been adopted. The cost of the work is estimated at $26,000.

MARQUETTE, MICH.—The officials of this city have decided to expend the sum of $25,000 in improving the water-works system.

GAFFNEY CITY, S. D.—It is probable that the proposed water-works at this place will be established at once. Important information can be obtained by addressing the Town Clerk

MENASHA, WIS.—Reports say that a system of water-works is proposed for this place.

WATER VALLEY, MISS.—The city will hold an election September 29, on a proposition to issue $10,000 of bonds for the construction of water-works.

LOS ANGELES, CAL.—The West Riverside Land and Water Co., of this place, has filed articles of incorporation. The directors are: G. A. Fredricker, Shirley C. Ward and others. The capital stock is $100,000.

COLUMBIA, S. C.—The sum of $30,000 is to be expended in building gates at the canal and doing other work on the water-works plant. Address Mayor F. W. McMaster for particulars.

IRON MOUNTAIN, MICH.—A company with $75,000 capital has been organized, to be known as the Iron Mountain Water-Works Company, for the purpose of constructing and operating a system of water-works at this place. The company holds a franchise for 30 years from Iron Mountain, and will receive $9,000 annually for 156 hydrants, with $50 for each extra hydrant required. W. R. Coats will superintend the work as engineer.

HOPKINSVILLE, KY.—It is reported that a system of water-works is to be established at this place.

OCONOMOWOC, WIS.—There is a movement to establish a water works plant at this place at once. J. H. Thompson is interested.

TRENTON, TENN.—The people of this place have voted the sum of $20,000 for the purpose of establishing a complete system of water-works.

DANBURY, N. C.—It is reported that this place is to have water-works.

ST. PAUL, MINN.—The Minnesota Subway Conduit Company has been incorporated at this place. The capital stock is $10,000, and the project is to operate conduits and lay pipes conveying water from Lake Superior across Minnesota Point and Bay of Superior to the State line between Minnesota and Wisconsin.

HEMPSTEAD, TEX.—The people of this place have requested the officials to consider the water-works question. For particulars address C. C. Anisler, as above.

SOUTH PITTSBURG, TENN.—A water-works system is to be established at this place by the South Pittsburg City Water Company. The capital stock is $50,000, and Mr. Hyde is the Secretary.

PORTLAND, ME.—Improvements are to be made to the local water-works plant.

KEITHSBURG, ILL.—It is likely that operations will commence at once on the water-works system projected for this place.

CRESTON, IOWA.—The water-works at this place will be completed by a newly organized company, with a capital stock of $30,000.

BROOKVILLE, IND.—The taxpayers of this place are united for water-works, and the officials will consider the question at an early day.

MILBURN, N. J.—It is probable that a contract will be made with the Commonwealth Water Company, of Summit, N. J., for a water supply for this place. Several miles of pipe will be wanted in the event of the closing of the contract.

PUEBLO, COL.—The Pueblo Water Company has been incorporated by H. J. Fitch and others. The objects include the laying of pipes in Bessemer and Pueblo. Capital stock, $300,000.

PERU, ILL.—The committee to which was referred the proposition of the Peru Electric Light Company to put in water-works has recommended that a franchise be granted.

BLOOMINGTON, IND.—This place has voted for water-works. Information can be had by addressing Jessie Starr, as above.

BROOKFIELD, MO.—A committee which has been investigating the matter has reported in favor of establishing a system of water-works.

PALO, MICH.—Rumors say that a system of water-works is to be established at this place.

FRANKLIN, IND.—This place is to have a system of water-works established by the Franklin Water, Light and Power Company. The proposed expenditure is $100,000.

SPOKANE FALLS, WASH.—Oskar Huber, City Engineer, writes: "In regard to the contemplated reconstruction of water-works I can inform you that I am preparing plans for a system. I will furnish you a copy as soon as they are completed."

GAINESVILLE, GA.—The following bids for the construction of a complete system of water-works were received by E. P. Chambers, Water Commissioner's Clerk, August 26: J. R. Davis, Atlanta, Ga., $31,500; Faulkner, Killour & Moore, $34,430; J. G. Longstreet, Gainesville, Ga., $38,440; A. D. Candler, Washington, D. C., $39,000. The Water Commission rejected all bids. It will build itself, and is now ready for other bids.

GUTHRIE, OKLA.—Village Clerk George M. De Groff writes: "No change is anticipated at the water-works at present. Can give you more information in relation thereto some time in the near future, perhaps 30 or 60 days."

DELHI, N. Y.—Regarding the report that the water-works at this place were to be improved, Town Clerk R. P. McIntosh writes: "No important additions or improvements are to be made in the Delhi works this season that I am able to ascertain."

LEONARDSVILLE, N. Y.—A new reservoir and additional water mains are among the proposed improvements to the local water-works system. H. D. Babcock can furnish particulars.

HOOSICK FALLS, N. Y.—The matter of procuring a water supply has been referred to a special committee, of which Charles Q. Eldredge is chairman.

SAN JOSE, CAL.—The Glen Weber Water Company has filed articles of incorporation, with a capital stock of $2,000,000. Its purposes are to furnish water for drinking and for mechanical power to the cities of San Francisco, Oakland and San Jose.

ROCKVILLE CENTER, L. I.—The people of this place are moving towards the establishment of water-works. Daniel Van Allen, representing the Hempstead Township Water-Works, has been canvassing the village with a petition with this end in view, and has secured the signatures of nearly every real estate owner.

LENOIR, TENN.—A system of water-works is to be established at this place.

EUSTIS, FLA.—According to the plans submitted, the projected water-works for this place will cost $20,000. Steps are now being taken to proceed with the construction of a system. Address Colonel Hazzard for particulars.

ESTHERVILLE, IOWA.—There is a probability that a system of water-works will soon be established at this place.

SOUTH BEND, IND.—Reports say that improvements are soon to be made to the local water-works.

MADISON, N. J.—The following bids for furnishing materials and labor required to build a system of water-works were received by Borough Clerk F. E. Day, August 29:

BIDDERS.	Pipe.	Hydrants.	Special Castings.	Supply Well, per foot.	Pump Station.	Boilers.	Tower.	Street Valve Boxes.	Pump.	Total.
Moffitt, Hodgkins & Clark, Syracuse, N. Y*	......	$25.00	......	......	......	......	$6,950.00 5,690.00	$3.00	......	$56,925.00

WILTON, IOWA.—The sum of $14,000 has been appropriated by the taxpayers of this place for the purpose of establishing a system of water-works.

LOUISVILLE, KY.—Reports say a movement is being discussed to place new pumps at the water-works station. Address the Mayor for particulars.

PALMYRA, MO.—The Palmyra Light and Water Co. has been incorporated to establish a system of water-works at this place. The capital stock is $50,000.

HAMILTON, ONT.—The question of introducing water meters is being considered by the city officials. Adlerman Dixon, of the Water-Works Committee, can furnish particulars.

ALTOONA, PA. — There is some talk of establishing an additional reservoir at this place.

SAN LUCAS, CAL.—The water-works question is being agitated at this place.

ROCHELLE, GA. — The taxpayers of this place want a water-works system.

CARLSTADT, N. J.—The people of this place are agitating the water-works question.

KINGSLAND, N. J.—Water-works will probably be established at this place soon.

ARLINGTON, N. J.—The local officials are discussing the water-works question.

LYNDHURST, N. J.—It is probable that this place will have a water supply.

RUTHERFORD, N. J.—A movement is on foot to establish a system of water-works at this place.

COHOES, N. Y. — At a meeting of the Water Commissioners held September 1, numerous water pipe extensions were authorized. For particulars, address President Thorn, of the Board, as above.

MADISON, FLA.—Reports say that a system of water-works is projected for this place and that J. A. Durst can furnish particulars.

AURORA, NEB.—The people of this place voted on August 26 to issue bonds in the sum of $7,000 for the purpose of making improvements to the water-works system.

ELMHURST, ILL.—It is proposed to establish a system of water-works at this place, at an estimated expenditure of $50,000.

NEW YORK CITY.—The Aqueduct Commission has awarded the contract for building the dam at Reservoir D, on the Croton River, near Carmel, to Michael S. Coleman, the lowest bidder, at $397,262.50.

NORFOLK, VA.—The Water Board has recommended the purchase of a 10,000,000-gallon pumping engine and proposals will soon be wanted for furnishing it. President W. A. S. Taylor can furnish particulars.

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Newport, Ky.; Blue Hill, Neb.; Coldwater, Mich.; Yoakum, Tex.; Allegheny, Pa.; Austin, Tex.; Atlanta, Ga.

READERS of **THE ENGINEERING AND BUILDING RECORD** interested in the Contracting News Department of that paper are respectfully requested to examine those columns every week, and advise the Editor of any item which they may find that, in their judgment, is of no value to any one other than the person mentioned.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

PIERCE, NEB.—Geo. A. Latimer, civil engineer, of Norfolk, Neb., has completed plans and submitted his report, with estimates, for a system of sewerage and grades for this city. The plans were adopted, and work will be begun this season.

CARLSTADT, N. J.—A system of sewers is wanted here.

ARLINGTON, N. J.—The question of establishing a sewerage system is being discussed at this place.

ROCKFORD, ILL.—A project to construct a 24-inch central sewer is being discussed by the local officials. Should it be done 6,000 feet of pipe will be wanted and the sum of $15,000 will be expended.

LOWELL, MASS.—The question of borrowing the sum of $50,000 for the construction of additional sewers and drains, is now being considered by the aldermen, who will, it is said, grant the action at an early day.

Vicksburg, Miss.—Engineer Hayney has completed plans, specifications, etc., for a sewerage system for this city and steps towards its construction will soon be taken.

Davenport, Iowa.—The question of a proper system of sewerage is engaging the attention of the local officials.

Wilmington, Del.—Sewer extensions will be made here.

Des Moines, Iowa.—Sewer extensions are to be constructed at this place.

Norristown, Pa.—Additional sewers are to be established at this place. Address Councilman Adam Youngman for particulars.

Kingsland, N. J.—Sewers are to be introduced at this place.

Willimantic, Conn.—At a special borough meeting it was voted to construct numerous additional sewer mains. Address the Borough Clerk for particulars.

Lyndhurst, N. J.—It is probable that steps will soon be taken to establish a system of sewers here.

Rutherford, N. J.—The people of this place want a system of sewers.

Troy, N. Y.—At a recent meeting of the Public Improvement Commissioners, the construction of numerous additional sewers was authorized.

Sewers.—See our Proposal Columns for information regarding sewer construction at the following places: Avondale, O.; Elizabeth, N. J.; Buffalo, N. Y.; Binghamton, N. Y.; Somerville, N. J.; Cairo, Ill.; Wilmington, Del.; Para, Brazil; Key West, Fla.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

Minneapolis, Minn.—The following proposals for fourteen 52-inch iron plate girders to carry the tracks of the Great Western Railroad, on Fifteenth Avenue, S. E. Estimated weight 240,000 pounds. The figures given are for f. o. b. cars at Minneapolis, per pound, and per pound erected ready for ties. Bidders: A. Y. Bayne, Minneapolis, 3.8c., 4.3c.; King Iron Bridge and Manufacturing Company, 3.98c., 4.28c.; Schiffler Bridge Works, 3.80c., 4.25c.; Wrought Iron Bridge Company, 4.16c., 4.66c.; Chicago Forge and Bolt Company, 3.395c.; 3.675c.; Chicago Bridge and Iron Works, 3.75c., 4.00c.; A. & P. Roberts & Co., Philadelphia, 3.73c., 4.43c.; Wisconsin Bridge Company, 4.125c., 4.70c.; Milwaukee Bridge and Iron Works, 3.84c., 4.24c.; Pottsville Iron and Steel Company, 3.59c.; Lassig Bridge and Iron Works, 3.425c., 3.90c.; Edge Moor Bridge Works, 3.55c., 4.15c.; F. T. Harrington, Minneapolis, 3.8c., 4.15c.; Keystone Bridge Company, 3.69c., 4.3cc. The contract was awarded to Chicago Forge and Bolt Company.

Carrollton, Ky.—Town Clerk R. J. Wilson writes: "There is an iron bridge to be built about four miles from here over McCole's Creek. Write to William Linsday, Committee."

Bryan, Tex.—Reports say that an iron bridge is to be erected over the Navasota River at this place.

Dallas, Tex.—According to numerous reports another bridge is to be erected over the Trinity River at this place.

New Haven, Conn.—City Engineer Hill states that the present bridge over Mill River on Chapel Street, New Haven, is not substantial enough for the traffic over it, and is of the opinion that a new bridge should be built as soon as practicable.

Willimantic, Conn.—At a meeting of the borough officials, held August 30, the committee on the bridge question reported that a foot-bridge could be constructed across the railroad tracks and Willimantic River, from Main to Pleasant Streets, for $11.500. The report was accepted, and it was voted to continue the committee and have it ascertain what share of the expense of either a drive or foot-bridge would devolve on the town. It was also stated a drive-bridge could be built for $25,000.

Duluth, Minn.—The question of bridging the Duluth Canal is in the hands of T. A. Thompson, Secretary of the Duluth Chamber of Commerce.

Bowmanville, Tex.—The Town Council has accepted the tender of the Trenton Bridge Company for a steel bridge of two spans, 85 feet long and 18 feet wide, for $5,320.

Brookline, Mass.—At a recent meeting of the Brookline Board of Selectmen a petition from the Boston and Albany Railroad Company was received asking for the bridging of the road at St. Mary's Street. The Board gave notice of its intention to call a town meeting on or about Thursday, September 18.

Detroit, Mich.—The Special Committee on Bridges has conferred with President Ledyard, of the Michigan Central, regarding the bridges over the tracks of that road at Lafayette Avenue, Twelfth, Fourteenth, Fifteenth, Howard and Baker Streets. It was decided that Chief Engineer Hawks, of the Michigan Central, and the City Engineer should meet and arrange a plan for building the bridges, fixing the grades, etc., and make their report to the committee.

Denison, Tex.—Reports say that this city will construct a 1,000-foot viaduct over the yards of the Missouri, Kansas and Texas Railroad and the Houston and Texas Central Railroad.

Duluth, Minn.—The Board of Public Works has awarded the King Iron Bridge and Manufacturing Company, of Cleveland, the contract for the iron work of Howard's Pocket bridge, for $27,100. There were six bids ranging from this amount to $28,600.

Richmond, Va.—The contract has been awarded to the Edge Moor Bridge Works, Edge Moor, Del., for building an iron- and steel highway viaduct 1,200 feet long and 40 feet wide and 75 feet high, connecting the properties of the Highland Park and Northside land companies with Richmond, Va. The contract price is $74,000.

Trenton, N. J.—The Board of Chosen Freeholders has resolved to build an iron bridge on the road leading from the Scotch road to Ewing. It will be an 18-foot span. Freeholders Maguire, Risdon and Ege were appointed the committee.

Olympia, Wash.—Plans have been submitted to the City Council of Olympia for the construction of an east side bridge, to cost $5,000.

Auburn, Me.—The following bids were received September 1 for an iron viaduct, 300 feet long, with 24-foot roadway and two 5-foot sidewalks: Dean & Westbrook, New York, $6,345; Groton Bridge Company, Groton, N. Y., $6,650; Pittsburg Bridge Company, Pittsburg, Pa., $7,450; Berlin Iron Bridge Company, East Berlin, Conn., $7,500. Each bidder presented his own designs. Contract awarded to Dean & Westbrook.

St. Charles, Mo.—The Senate has passed the House bill for the erection of a pontoon bridge across the Missouri River between this city and St. Louis County, Mo.

Bridgeport, Conn.—The Senators and Representatives of Fairfield County met in this city August 27, and settled the matter in regard to building a new bridge over the Housatonic River, between the towns of Huntington and Derby. They authorized the County Commissioners to go ahead, and in conjunction with the Commissioners of New Haven County build such a bridge as would accommodate and meet the demands of the public. They authorize them to borrow the sum of $35,000 to pay the part of the expense due from Fairfield County. The new bridge will probably be of iron or steel and cost about $70,000. The Building Committee, which will consist of the Boards of County Commissioners of Fairfield and New Haven counties, will shortly advertise for plans and specifications.

The Contracting News Department of **THE ENGINEERING AND BUILDING RECORD** is edited with a view of giving space to no item that does not indicate where professional services or supplies may be needed in the near future, the prices bid for work or supplies, and the correction of false or misleading reports in some papers, that may subject readers to needless trouble and expense in going after something that does not exist.

Pittsburg, Pa.—A sub-committe of Allegheny Councils will soon meet and examine the plans for the Federal Street approach to the new Sixth Street bridge. The directors of the bridge company will also hold a meeting and select the designs for the structure from a number of plans presented. It is reported that the Lindenthal design will be approved. It calls for a bridge to cost nearly $500,000. It will be built so that either cable or electric cars can be run over it at any required rate of speed. Colonel Merrill, United States Engineer, has already been consulted, and has entered into an agreement as to the height of the structure above the water level.

Boston, Mass.—The following proposals for the erection of the River Street bridge to Cambridge were opened August 25 by the Engineering Department. Bidders: Alexander McInnis, Winthrop, $12,500; William A. Norton, Boston, $14,500; B. F. Nay & W. H. Ellis, Boston, $17,700; John Cavanagh & Co., Braintree, $17,800; J. H. White & E. R. Cheney, Boston and Chelsea, $18,426; George Ellis, Boston, $19,632. Awarded to Alexander McInnis.

Hartford, Conn.—Judge Adams, chairman of the Park Commission, can furnish information of a proposed bridge at this place.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: Northampton, Mass.; New Gretna, N. J.

NEW DEPOTS.

St. Louis, Mo.—It is stated that a meeting of the Union Depot and Terminal Company will be held in New York on or about the 20th of the present month, and at that time the location of the new station will be decided. Architects are at work on plans for the building.

STREET-WORK AND PAVING.

East Liveepool, O.—The paving of several of the city streets has been authorized. Address President Hanley, of the Common Council, for particulars.

Des Moines, Iowa. — Important street paving is to be done in this city.

Pine Bluff, Ark.—Numerous streets of this place are soon to be paved. Address the City Clerk, for details.

Kalamazoo, Mich.—It has been decided to begin the work of street paving at once. Alderman E. McCaffrey can furnish particulars.

GAS AND ELECTRIC-LIGHTING.

New Orleans, La. — Rumors say that another electric light plant will be established at this place by the Consumers' Electric Light Company.

Silverton, Col.—The Silverton Electric Light and Power Company has been granted a franchise to erect and maintain an electric light plant.

Portage, Man.—An electric light plant is to be established at this place by the Central Electric Light Company. For particulars address Robert Watson, as above.

Water Valley, Miss.—An electric light plant is talked of for this place.

Chester, S. C.—At a recent town meeting it was voted to authorize the Council to contract for a system of electric street lighting, provided it can be done at a cost not exceeding $2,000 per annum.

Marion, N. C. — A company has been organized at this place for the purpose of establishing an electric lighting plant.

Exeter, N. H.—This place is to have electric lights.

Humboldt, N. C.—Operations are to be begun at once on the projected electric light plant for this place.

Keokuk, Ia.—The J. C. Nubinger Co. has been incorporated here, with a capital stock of $1,000,000, for the purpose of furnishing electricity for light and power. J. C. Nubinger is the manager.

Willamette, Ore.—The Falls Electric Light Co., of this place, will increase the capacity of its plant by the addition of 1,500 incandescent and 100 arc lights.

Lyndhurst, N. J.—The local officials will probably establish an electric lighting plant soon.

Kingsland, N. J.—Steps towards establishing an electric lighting plant at this place are being taken.

Waynesboro, Ga. — The Waynesboro Electric Light Co. has been organized here, with a capital stock of $7,500. Incorporators: A. G. Whitehead, P. L. Corker and others.

Chattanooga, Tenn.—The Farrell Electric Light, Heat and Steam Co. has been incorporated here. J. A. Hart is interested.

Florence, S. C.—Electric lights are talked of for this place.

Marion, Pa.—The Indiana County Gas Co. has been incorporated to establish a plant here. The capital stock is $50,000. Address M. C. Watson, as above, for details.

Glasgow, Va.—It is probable that the electric light plant projected for this place will be established at once.

Portland, Me.—The Orient Electric Company will establish an electric light plant at this place.

Buckhannon, W. Va.—An electric light plant is to be established at this place by the Buckhannon Electric Light Company, of which G. M. Fleming is President. The capital stock is $7,000.

Hopkinsville, Ky.—An electric lighting plant is to be established at this place.

Sacramento City, Cal.—The California Gas Light and Fuel Company has filed articles of incorporation. Directors, H. B. Smith, Jr., of Alameda, and others. Capital stock, $10,000,000.

Rockport, Tex.—Propositions have been made to construct an electric lighting plant at this place.

San Francisco, Cal.—The Tulare Electric Light and Power Company has been incorporated here with a capital stock of $50,000. Directors, Messrs. F. W. Eaton, John C. Turner and others.

Ottawa, Can.—Improvements will probably be made to the Plant of the Chandiore Electric Light and Power Company of this place.

Los Angeles, Cal.—The Columbia Steam and Gas Company has been incorporated here with a capital stock of $100,000. Directors, L. E. Fish, R. W. Hinckley, and others.

Yazoo City, Miss.—Operations will begin at once on the electric light plant to be established at this place.

Hornellsville, N.Y.—The Steuben Electric Manufacturing Company of this place has been incorporated with a capital stock of $30,000. Incorporators, Charles Adsit, George A. Bronson, and others.

West Winfield, N. Y.—An electric light plant is to be established at this place at an early day. For particulars, address P. McFarland, as above.

Columbus, O.—Additional bonds for gas and lighting purposes will probably be issued soon.

Titusville, Fla.—The sum of $10,000 is to be expended on an electric lighting plant for this place.

St. Joseph, Mo.—Numerous new lights are to be added to the local electric lighting plant.

Cedar Rapids, Iowa.—Improvements are to be made to the local electric light plant.

Newark, N. J.—Improvements are to be made to the plant of the Consolidated Newark and Schuyler Electric Light Company. The estimated expenditure is $150,000.

Sag Harbor, L. I.—An electric lighting plant is to be established at this place by the Fahys Watch Case Company.

Portland, Me.—At a recent meeting of the City Council an order was passed authorizing the Committee on Street Lamps to contract with some responsible party for lighting the streets for the year ending October 31, 1891.

Wilton, Iowa.—This place is to have electric lights.

Palmyra, Mo.—An electric light plant is to be established at this place.

Mount Pleasant, Mich.—This place is to have an electric lighting plant.

Rutherford, N. J.—An electric light plant is wanted here.

Carlstadt, N. J.—This place will have electric lights.

ELECTRIC RAILWAYS.—New electric railways will be built and improvements will be made to those already established at the following places: Omosso City, Mich.; Newport, Ky.; Argentine, Mo.; Armourdale, Mo.; Westport, Mo.; Independence, Mo.; Centropolis, Mo.; Sheffield, Mo.; Harlem, Mo.; Memphis, Tenn.; Ottawa, Can.; Rockland, Me.; Ann Arbor, Mich.; Ypsilanti, Mich.; Springfield, Ill.

BIDS OPENED.

PEORIA, ILL.—The contract for the construction of the House of the Good Shepherd has been awarded to Peter Kinney & Sons for $18,793. Wechselberger & Reeves, architects, will superintend.

LOCKPORT, N. Y.—Reports say that contract for constructing the tunnel at Niagara Falls has been awarded to Rogers & Clement, of New York. The figure is not given.

BOSTON, MASS.—The following proposals for filling in on parkway, Tremont and Longwood entrances, Back Bay, were opened September 3, by the Park Department: Boston and Albany Railroad Company, Boston, Mass., per cubic yard, 51 cents; total, $61,200. Finnerty & Kelley, Boston, Mass., per cubic yard, 90 cents; total, $108,000. The lowest bidder got the contract.

Proposals for doing the Marine Park filling were opened on the same date, as follows: The first figures are for 200,000 cubic yards, and the second figures are for 400,000 cubic yards. Bidders: Perkins & White, Boston, Mass., $114,000 and $212,000; Eastern Dredging Company, Boston, Mass., $118,000 and $216,000; New England Dredging Company, Boston, Mass., $134,000 and $292,000. The contract was awarded to Perkins & White.

GOVERNMENT WORK.

OPELOUSAS, LA.—The following proposals for the erection and completion, except heating, of the United States Court House and Post Office at this place, were opened August 28, advertisement of August 2, by the Supervising Architect of the Treasury Department. The figures given are for the following work, in detail, in its respective order: 1, total amount; 2, price per cubic yard for additional granite bearing plates; 3, amount for extra plate glass throughout, except basement; 4, extra white oak in first and second stories; 5, price per cubic yard for excavation; 6, price per yard for concrete; 7, price per M. for selected bricks in wall; 8, price per M. for red brick in wall and piers; 9, kind of stone. Bidders: Robert M. Jack, Wichita, La., $40,000, $2.25, $900, $700, 50c., $6, $65, $17, Bedford; W. D. Southwell, New Orleans, La., $48,900, $2.50, $800, $1,050, 64c., $14.50, $60, $20.50; Bedford House; George Van Horn; New Orleans, La., $39,362, $2.25, $1,200, $1,000, 50c., $6, $60, $16, Indiana limestone; W. E. Speer & Co., New Orleans, La., $43,552.56, $3.50, $1,300, $2,000, 55c., $7.50, $65, $19.50, Bedford.

INDUSTRIAL.

MINNEAPOLIS, MINN.—The permanent improvements for Minneapolis for another year are to cost about $600,000.

NEWPORT, KY.—Reports say that the Swift Iron and Steel Works of this place has been bought by the Ironton Steel Works Company, and that it will be rebuilt and enlarged.

ELIZABETH CITY, N. C.—The city will hold an election September 8 to decide as to issuance of $10,000 of bonds for improvements.

PROPOSALS.

(Continued from page ii.)

WHARF, Boston, Mass.—Proposals are wanted until September 10, for the construction of a wharf at Deer Island. Address Howard A. Carson, Chief Engineer, Metropolitan Sewerage Commission, as above.

WATER-WORKS, Coldwater, Mich.—Proposals are wanted until September 16, for the construction of a complete system of water-works. Address J. D. Cook, Consulting Engineer, Toledo, O.

SEWERS, Cairo, Ill.—Proposals are wanted until September 9, for the construction of certain sewers. Address Casey Stiles, City Clerk, as above.

SEWERS, Binghamton, N. Y.—Proposals are wanted until September 8, for the construction of certain sewers at this place. Address W. J. Flanigan, City Clerk, as above.

TOWN HALL, Fern Bank, O.—Proposals are wanted until September 29, for the erection of a town hall at this place. Address T. Forman, Corporation Clerk, as above.

SEWERS, Wilmington, Del.—Proposals are wanted until September 11, for the construction of certain sewers. Address T. Chalkley Hatton, engineer in charge of sewers, as above.

POSITIONS VACANT.

TOO LATE FOR CLASSIFICATION.

WANTED AT ONCE.—A FIRST CLASS draughtsman, well up in detail drawings for bridges and roofs; none but experienced man need apply; also, a junior draughtsman, who must be a good tracer. Apply to NATHANIEL ROBERTS, Engineer, Wallis Iron Works, Jersey City.

POSITIONS WANTED.

A GRADUATE IN CIVIL ENGINEERING wishes permanent position in any department of civil engineering. Address F. G. DODD, Nutley, N. J.

WANTED—A SITUATION BY A YOUNG man to finish his time at the plumbing business. Has had three and a-half years' experience in plumbing and gas fitting. Industrious and willing. Can furnish the best of city reference. Address T. WALSH, Plainfield, N. J.

Building Intelligence.

We solicit from each and every one of our readers information relating to projected buildings in their locality, and should be glad to receive newspaper clippings and other items of interest.

THE Editor of THE ENGINEERING AND BUILDING RECORD is always glad to receive items of news for the Contracting News Department. But such items are not considered news except when the prices and particulars of the award of a contract are given.

The announcement that ——— has sold ——— to ——— without giving the *prices* and particulars concerns only the buyer and seller. Such notices are always excluded, except in the case where a certain firm is stated to have taken a certain contract, the execution of which would require that they should buy certain materials. Such an item would be used if deemed of more than local interest, because it would suggest to some readers the possibility of their making a sale or securing a subcontract.

232–42 Wells st, br store and flats; cost, $80,000; o, W S Johnston; a, Hy Gres Cobb; b, Jno Mountain.

37–45 Union Park Place, br factory; cost, $22,000; o, Chas E Hersen; a, J M Van Osdel & Co; b, A Loudquest.

Randolph and Clark sts, br story addition; cost, $13,000; o, Ashland Block; a, W L B Jenney; b, Geo A Fuller & Co.

46–48 Astor st, br dwell; cost, $32,000; o, W C Goudey; a, Burnham & Root; b, C W Demier & Co.

2624 Cottage Grove av, br store and flats; cost, $10,000; o, Hy Wachter; a, Furst & Rudolph; b, Geo Schneider.

Br structure; cost, $85,000; o, The Chicago Atheneum; a, Thos Wing.

29th st and Wabash av, br store and apartment house; cost, $40,000; o, Geo V Hantins; a, same as above.

Cor Ashland bl and Polk st, 3-story dwell. cost, $35,000; o, Mrs Minnie Morris; a, J E Thorn.

166 bldgs costing less than $7,000 each.

DENVER, COL.—24th av, bet Downing and Ogden, br terrace; cost, $10,000; o, Flower & Patterson; a, Balcomb & Rice.

32d av, bet Race and Wine, br terrace; cost, $16,000; o and a, Thos Freeman.

S 15th, cor 9th av, double br dwell; cost, $20,000; o, E M Holiday; a, Andrews, Jaques & Rantoul.

Ogden, bet 23d and 24th av, br terrace; cost, $10,000; o and a, Van Stone Bros.

Alemeda, bet Alta and Porter, 3 br dwells; cost, $10,000; o and a, J H Harmed.

High, bet Colfax and 16th av, 3 br dwells; cost, $16,500; o, A E Hull; a, Lang & Pugh.

DETROIT, MICH.—Howard st, bet 10th and 12th sts, 2 story br double res; cost, $7,000; o, Wm E Maloney; a, A E French.

FINDLAY, O.—West Park, fr factory bldg for the manufacture of glass bottles; cost, $8,000; o, B F Morrical, President of stock company; a, G J Horn; b, not let.

FOND DU LAC, WIS.—Fr dwell; cost, $7,000, o, W H Mihills; a, Conover & Porter of Madison.

HOLYOKE, MASS.—Cor High and John, 5-story bus block; o and b, John Cleary.

LEXINGTON, KY.—J F Alexander, architect, of Peoria, Ill., has completed plans for a public library building here to cost $150,000. It will be heated by the hot air system.

BUILDING INTELLIGENCE.

JOHNSTOWN, PA.—Cor Clinton and Locust st, br block, marble trimmings, for store and office purposes; cost, 25,000; o, Chas S Ruth; a and b, George Krueger.

Clinton st, br block, cost, $11,500; o, C Krieger; a and b, same as above.

Broad st and 3d av, pressed brick church and school; cost, $27,000; o, Rev E W Trautwein; b, Geo Krueger.

Bedford st, pressed brick bldg; cost, $7,500; o, J Zimmerman; a and b, George Krueger.

LANCASTER, PA. — Br residence; cost, $8,000; o, Henry Mettfett; a, Clifton Evans; b, Robert Morrow.

LANSING, MICH.—Baird's Opera House; cost, $30,000; o, Jas W Baird; a, Robbins & Charpie.

LONDON, ONT. — Banking house remodeled; cost, $7,000; o, Erie & Huron Loan Ass'n; a, Spier & Rohns, Detroit, Mich.

MADISON, WIS.—Fr dwell; cost, $7,000; o, Dr Jastrow; a, Conover & Porter.

Br block; cost, $12,000; o, Democrat Printing Co; a, O J Williams.

MEADVILLE, PA.—Mercer st, annex to Phœnix Iron Works, 40x75 feet; cost, with machinery, $25,000; o, Phœnix Iron Co; designed and building by their own men; Henry Church, manager.

MILWAUKEE, WIS.—Park st and Muskegon av, factory; cost, $7,000; o, Milwaukee Harvester Co; a, A J Inglis.

MINNEAPOLIS, MINN.—619–21 Nic av, br store bldg; cost, $60,000; o, Dickinson & Cumington, Willis & Dunham; a, W C Whitney.

Cor 6th s and 1st av, br club house; cost, $75,000; o, Minneapolis Club; a, as above.

519–25 3d av, N E., fr ten; cost, $15,000; o and b, Robert O'Brien; a, T W Kelley.

Cor Winter and Tyler sts, br round house; cost, $25,000; o, Great Northern Ry Co; b, A H Hogsland.

St Louis Ry nr Cedar Lake, br machine shop; cost, $25,000; o, Minneapolis and St Louis Ry Co; a, W B Hickson.

PITTSFIELD, MASS.—Two-story br electric light station; cost, $30,000; b, Hascal Dodge.

RHINELANDER, WIS.—Br School-house; cost, $10,000; o, city; a, Conover & Porter, Madison.

SALT LAKE CITY, UTAH. — Seventh South st, 3 dwells; cost, $9,000; o, Bolton, Hendricks & Co; a, Thompson & Weigel.

Owen st, 4 dwells; cost, $8,000; o, R B Hickock; a, W E Ware.

SCRANTON, PA.—Hyde Park, fr church; cost, $7,000; o, St David's Episcopal; a, F L Brown; b, W R Williams.

Wyoming av, s bank and office bldg; cost, $12,000; o, Chas Schlager; a, as above; b, subdivided contracts.

Clay av, s and fr res; cost, $13,000; o, E P Kingsbury; a, Mr. Holden; b, Conrad Schroeder.

Pennsylvania av, br store and office bldg; cost, $14,000; o, Mr Bloeder; a, F L Brown; b, as above.

SIOUX CITY, IOWA.—Leech st, in Greenville, addn to Sioux City, sausage factory; cost, $70,000; o and a, Adolph Heller; b, J P Wall.

SOUTH BETHLEHEM, PA.—Catasauqua, stone and shingle dwell; cost, about 9,000; o, Mr F Fuller; b, no contract.

SOUTH BRAINTREE, MASS.—Pearl st, granite depot; o, Old Colony Railroad; b, contract not yet let.

SOUTH SCRANTON, PA.—Convent; cost, $12,000; o, R C Congregation, parish of St Johns; a, Fred J Amsden, b, Boland & Battle.

ST. PAUL, MINN.—Grand av nr Avon, 2-story addn to br school; cost, $16,000; o, Board of Education.

Arcade nr Sims, 2-story br dwell; cost, $7,000; o, Chas Nordin.

BUILDING INTELLIGENCE.

ST. LOUIS, MO.—Page and Newstead avs, br dwell; cost, $7,000; o and b, J W Barness & Co.

Washington and Compton avs, br dwell; cost, $16,000; o, Pechman Bros; b, Wm Rieme & Son.

Wharf and Madison st, elevator; cost, $20,000; o, Farmers' Elevator Company; b, Hill & Kirgin.

S e cor Lafayette and Iowa avs, br dwell; cost, $9,500; o, J Schnaider; b, J H Remmers.

Jefferson and Wyoming avs, br dwell; cost, $8,400; o, Jannoponto & Gotsch; b, F Thoms.

Shaw's Garden, br dwell; cost, $10,000; o, Trustees Missouri Botanical Gardens; b, J W Givens.

TERRE HAUTE, IND.—Grand stand; o, Terre Haute Driving Club; a, W E Brown.

WORCESTER, MASS.—Pleasant, br bus block; cost, $20,000; o, R C Taylor; a, Cutting & Forbush; b, not let.

BUILDINGS.—There is nothing over $7,000 in value to report at the following places: Charleston, S. C.; Ogdensburg, N. Y.; Pottstown, Pa.; Wilkes Barre, Pa.; San Antonio, Tex.; Galveston, Tex.; Dennison, O.; Geneva, N. Y.; Waco, Tex.; Dayton, O.; Canton, O.; Saginaw, Mich.; Springfield, O.

TECHNICAL BOOKS.

ASIDE from our own publications the Book Department has for several years made a specialty of supplying all the latest technical books, particularly those in which the readers of this journal are especially interested.

Orders will be promptly filled, postage free, on receipt of published price.

"PLUMBING PRACTICE."

BY

J. WRIGHT CLARKE.

This contains articles on "English Plumbing Practice," which appeared in THE ENGINEERING AND BUILDING RECORD and THE SANITARY ENGINEER from 1883 to 1887, with considerable additions.

Price $3.00.

ADDRESS, BOOK DEPARTMENT,
THE ENGINEERING & BUILDING RECORD,
277 PEARL STREET, NEW YORK.

WATER-WASTE PREVENTION: Its importance and the evils due to its neglect. By HENRY C. MEYER, Editor of The Engineering and Building Record.

(*From the Preface.*)

"If the publication of this little book increases the popular appreciation of an urgent public necessity, and tends to secure for water-works officials who are striving to do their duty in the matter of restricting the waste of water the support of influential members of their community, the author will feel amply repaid for the labor involved in gathering and presenting this information."

Price $1.00. *Sent post-paid on receipt of price.*

ADDRESS, BOOK DEPARTMENT,
THE ENGINEERING & BUILDING RECORD,
277 PEARL STREET, NEW YORK.

Obtainable at London Office, 92 and 93 Fleet Street, for 5*s*.

PAVEMENTS AND ROADS;

THEIR

CONSTRUCTION AND MAINTENANCE.

Large 8vo., pp. 410.

Handsomely Bound in Cloth. Sent Post-paid on Receipt of $5.00.

SOME PRESS COMMENTS:

A valuable manual.—*San Francisco Chronicle, July* 13, 1890.

The volume is one which has a practical value, and should be studied by all interested in road improvements.—*Troy Times, July* 21, 1890.

A book which should be in the hands of every country Roadmaster or city Superintendent of Streets. * * *

The whole question of improved roads is yet to be seriously considered in the country. We excel the World, perhaps, in the comforts and facilities of railway travel, but our common highways, outside the immediate vicinity of large cities, are on a par with those found only in half civilized foreign countries.

The time will doubtless come when some system of thorough road construction, under skilled State or County supervision, will be applied to the main highways, the chief arteries of travel in every county.—*Springfield Republican, July* 2, 1890.

A most creditable and seasonable compilation. It is decidedly the best collection of data on this important subject that has yet appeared in book form. —*Engineering News, June* 21, 1890.

* * * It should have a place, especially, in the offices of street and county commissioners, where its suggestions might soon contribute greatly to the commercial welfare, safety and convenience of thousands of communities in our land.—*Iron Age, June* 19, 1890.

One of the most useful, interesting and practical books which has lately been issued from the American Press, and which is, no doubt, destined to have an important influence on street and road making in this country. * * * A large and very valuable mass of information in regard to the subject. * * * —*Boston Herald, June* 9, 1890.

This portly volume of more than 400 large octavo pages contains a vast amount of information not easy to describe in a limited notice. It is chiefly a compilation of articles which have recently appeared in THE ENGINEERING AND BUILDING RECORD, and which give the result of the Editor's investigation of work on streets and roads in England, France and other countries. * * * The subject is one of special importance to taxpayers and those having charge of road construction, and is here treated in a practical and thorough manner. * * * Farmers and tradesmen are beginning to realize that while good roads are costly, poor roads cost the country still more.—*Cincinnati Times Star, July* 25, 1890.

Mr. Love has done a public service in bringing together this information on pavements and roads in book form. At present there is an urgent demand for practical knowledge of this kind, especially in this country, where we are now passing through a transition stage and seeking to better the condition of the thoroughfares. It must be confessed that, taken at large, the practice here has by no means been up to the best standards, though there are notable exceptions, as, for example, the streets of Washington and some of the suburban driveways. Consequently when it is sought to remodel systems, as is now being done in so many American cities, to say nothing of the country highways, it becomes necessary to seek for the guidance of the experience gained abroad in the thickly populated European countries, where heretofore the most attention has been paid to the subject, thus avoiding costly and unnecessary experiment in directions already explored. By concentrating in this compilation the results reached in foreign practice, Mr. Love places a fund of information at the disposal of officials and engineers who have not had the advantage of personally studying the European methods. At the same time he gives much space to discussions of American practice, hitherto contained mainly in the transactions of a few engineering societies, and available for the use of a limited number of engineers. The editing is to be commended for the selection of matter relating to actual experience, and capable of being tested and compared by means of the numerical results quoted. As might be expected in a compilation of the kind the student will sometimes meet with discrepancies in the statement of the claims of rival systems; but nothing is lost by presenting a wide option of method in a matter where the conditions to be met vary so greatly.

The material from which the book is made up originally appeared in THE ENGINEERING AND BUILDING RECORD of New York. The compiler has eliminated what was of merely temporary and local interest, and appears to have kept in view the idea of producing a reference book of general applicability. The statements of cost and endurance in different places, being based on the records of actual trials, will serve as valuable data for estimating corresponding cost and endurance in other places where the variation in conditions is exactly known, and this feature of the book is the most useful one. We think, too, that the compiler has done well in letting the contributors speak for themselves in presenting the claims of different systems and the results of their experience. —*The Engineering and Mining Journal, July* 12, 1890.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22.
NUMBER 15.

PUBLISHED EVERY SATURDAY.
277 PEARL ST., NEW YORK.

NEW YORK, SEPTEMBER 13, 1890.
LONDON, SEPTEMBER 27, 1890.

SINGLE COPIES, TEN CENTS.
Subscription, $4.00 per year in advance, post paid. IN AMERICA.
Subscription, 25s. per annum in advance, post paid IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at 277 Pearl Street, New York (P. O. Box 3037). Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.

25s. in GREAT BRITAIN. Other Foreign Countries $6.
Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & CO., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $6; China, Japan, Sandwich Islands, Mexico and Cuba, $6; South America, $6.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

EXPERT ADVICE TO ARCHITECTS.

ON another page will be found a letter from a well-known civil engineer, whose name is withheld because of his business and personal relationship to the subject discussed. This calls attention to a practice of some architects, which from time to time has been alluded to in these columns, namely, relying on contractors to prepare plans and drawings that should be furnished by the architects. We are glad to know that there is a growing number in the profession against whom this charge cannot be justly made, yet the evil still exists, and the root of it undoubtedly lies, as is pointed out by "Civil Engineer," in the fact that architects too often fail to promptly point out to a client the necessity of their being permitted to retain special advice to assist them in preparing plans for special structural features, which are now often required in complicated modern heavy buildings. The architect whose practice is mainly in small buildings always looks forward to the time when he can get into what is called large work—*i. e.*, public and commercial buildings. Yet sometimes from lack of private means, again from failure to fully appreciate them, he takes risks from which more experienced men shrink, saving a consulting engineer's fee with the melancholy results which we are from time to time called upon to chronicle. The fact is, that architects in their practice should be less inclined to lead clients to believe that they know all about the varied complicated features of modern building construction, incident to the unprecedentedly rapid development of the art within recent years. It is unreasonable to expect it, and they should frankly admit it. Their duty to themselves and to their client requires it.

A lawyer, a physician, or an engineer, whenever any problem out of the ordinary presents itself, informs his client that on this or that point he would like special counsel. All men of business who are identified with large interests, know what it is to have special counsel retained in all important matters, and an architect should have no difficulty in impressing this point upon his client, and that his present regular commission—which is too often entirely inadequate—will not pay for this special service, and that it is to the interest of the client to authorize such special employment, and pay for it.

On the occasion of the disaster to a building in another city a few years ago, and in the discussion which followed, it will be remembered that we successfully urged the recognition by the American Institute of Architects of the principle that in important building a clerk of works should be constantly employed, to be paid for by the owner. The propriety of an owner paying for special advice on special problems should also be recognized. Just where the line should be drawn as to what special advice the architect or the owner should pay for in the planning and construction of modern buildings, would seem to be a legitimate subject for the earnest consideration of the American Institute of Architects, and we commend it to them as a live question to be considered at their forthcoming convention. We know of instances where an architect, realizing the importance of having special advice, has paid for such services, and for the drawings incident to the proper completion of the building, a sum greater than he received in fees, relying upon his private fortune to make good the deficiency and protect his reputation. This is all wrong. The recognized scale of compensation should be adequate to the service rendered, so that successful practice will secure better pecuniary rewards than it yet has done.

BAD SEWER WORK.

REPORTS from Mount Vernon, N. Y., indicate that some very bad sewer work has been going on there. According to a report in the New York *Tribune*, the filling in over the sewer pipe showed the gravest violation of the terms of the contract. The contractor, Bryan, had removed a large quantity of sand from the trench and replaced it, to a depth of several feet, with stone blasted out at other points. This stone was thrown in loosely, with no earth between the pieces, leaving the pipes exposed to great injury. Many of the pieces of stone were two feet or more in length and between two and three feet across, notwithstanding the contract limits the size to five inches and requires all pieces to be separated by earth.

Such work as this indicates gross carelessness, ignorance, or corruption on the part of the inspector and he should be promptly removed. If there is any engineer who has been supposed to look after the construction he is also culpable. If, however, the engineer who prepared the plans is not employed to look after the work of construction it is high time he was, otherwise the taxpayers' money will be thrown away and the town have a series of elongated cesspools instead of a sewer.

POLITICS IN WATER-WORKS ENGINEERING.

THE Cincinnati *Commercial Gazette*, in commenting on the present unhappy condition of Cincinnati's water supply and water-works plant, points out that its pumping station and intake was located in 1839, when the population of the city did not exceed forty thousand The water was drawn from what is now below the limits of the city. But Cincinnati has outgrown all this, yet the water-works are in the same locality. The sewage above the city is discharged into the river above the present site of the pumping station. There are at this time more people east of the water-works, so-called, than were in the whole city of Cincinnati in 1840. There is a greater population in Walnut Hills at this time than the whole city contained fifty years ago. Yet the pumping station has not moved a foot. The tunnels that supply the wells are located precisely as they were half a century ago, and the water that is supplied to the people is drawn from the same source that was then pure, but is now impure.

Yet, in face of this experience, which has been published far and wide, we notice that a Public Works Commissioner, of Rochester, N Y., where the election of a water-works engineer is under discussion, said that he had no objection to going on record as in favor of a "*Democratic* engineer." Nothing was said about the importance of the man being a competent civil and hydraulic engineer, but the essential requisite seems to have been that he voted for the candidates of a particular party. It will be unfortunate for Rochester or any other place if this political test is to be applied in the selection of its engineering officials. It is to be hoped that the public-spirited citizens of Rochester, of both parties, will have influence enough to have political considerations eliminated in the selection of their water-works engineer.

Since the foregoing was put in type, we learn that Emil Kuichling, a well known engineer, has been selected. Happily wiser counsels prevailed.

KEEPING WALLS DRY.

In a recent issue of the London *Architect*, W. L. Dearborn explains Sylvester's process for keeping walls dry.

It consists in using two washes or solutions for covering the surface of the walls—one composed of Castile soap and water, and one of alum and water. The proportions are three-quarters of a pound of soap to one gallon of water, and half a pound of alum to four gallons of water, both substances to be perfectly dissolved in water before being used. The walls should be perfectly clean and dry, and the temperature of the air not above 50° Fahr. when the compositions are applied. The first, or soap wash, should be laid on when boiling hot, with a flat brush, taking care to form a froth on the brickwork. This wash should remain 24 hours so as to become dry and hard before the second, or alum, wash is applied, which should be done in the same manner as the first. The temperature of this wash when applied may be 60 or 70° Fahr., and this also should remain 24 hours before a second coat of the soap wash is put on. These coats are to be applied alternately until the walls are made impervious to water. The alum and soap thus combined form an insoluble compound, filling the pores of the masonry and entirely preventing the water from entering the walls.

The French post-office authorities have lately been making experiments with a new wire, known as the "bi-metallic Martin," composed of steel with a surface of copper. The result is that the wire has been adopted to replace the wires in the telegraph service, and it will also be used upon the telephone systems.

The Bell Telephone Company is putting its wires under ground at Montreal.

OBITUARY.

John Westinghouse, senior member of the Westinghouse Company, manufacturers of agricultural implements, of Schenectady, N. Y., and eldest brother of George Westinghouse, the inventor of the air brake, died in Schenectady on the 2d inst., aged 50.

Charles J. Harvey, City Engineer of St. Johns, Newfoundland, died this week. He was engaged in the construction of the city's new sewerage system.

PERSONAL.

William P. Butler, for 11 years Assistant City Engineer of Bloomington, Ill., has been elected City Engineer.

F. Kirschman, C. E., of Milwaukee, has been engaged to assist in the construction of the Wisconsin Midland Railway, upon which work has been begun at Fond du Lac. N. Boardman, of Fond du Lac, is consulting engineer.

Sir Benjamin Baker, late Chief Engineer of the Forth Bridge, is on his way to this country in the steamer Aurania, which will arrive to-day or to-morrow. He is Consulting Engineer to the Canadian Government, and will probably in that capacity visit the Chignecto Ship Railway, at the head of the Bay of Fundy.

The following changes in the U. S. A. Engineer Corps have been ordered: First Lieutenant John Millis has been relieved from duty at Tompkinsville, N. Y., and ordered to New Orleans, relieving Captain D. C. Kingman, who is ordered to Oswego, N. Y., to relieve Captain C. F. Palfrey.

Emil Kuichling has been chosen to be chief engineer of the Rochester, N. Y., water-works. Mr. Kuichling entered the University of Rochester in the fall of 1864 and graduated from the regular art course in 1868. He then took a post-graduate course, and in 1869 received the degree of civil engineer. After completing his post-graduate course at the university he took the full three years' civil engineering course at the Polytechnic School in Carlsrhue, Germany. Mr. Kuichling's official career in Rochester commenced in 1873.

ENGINEERING SOCIETIES.

The fifty-seventh meeting of the American Institute of Mining Engineers will be held in the city of New York, beginning Monday afternoon, September 29, 1890, at 2 o'clock. All sessions will be held in Chickering Hall, 130 Fifth Avenue. Hotel headquarters will be at the Park Avenue Hotel, 482 Fourth Avenue, where the Institute will also maintain during the month of October a post-office and bureau of information for members and guests. Applications for rooms and all other communications concerning the New York meeting (except such as relate to papers) should be addressed to James F. Lewis, chairman of the New York Local Committee, 23 Park Place, New York.

The following programme is provisionally announced: Sessions of the Institute for the reading and discussion of papers on Monday afternoon and evening and Thursday morning, afternoon and evening. On Wednesday, Thursday and Friday mornings the sessions of the British Iron and Steel Institute will take place. On Wednesday afternoon there will be an excursion of the two societies and invited guests upon the Hudson River.

On Thursday afternoon the Holley Memorial will be unveiled in Washington Square. The commemorative address will be delivered in Chickering Hall, previous to the open-air ceremony, by Mr. James Dredge, editor of London *Engineering*.

On Saturday, members and guests will proceed by special train to Philadelphia; on Tuesday, October 7, to Lebanon and Harrisburg, and on Wednesday to Johnstown and Altoona, arriving Wednesday evening at Pittsburg, according to the programme of the General Reception Committee.

At Pittsburg, two joint international sessions will be held by the two societies and their guests, for the reading of papers. Further announcement will be made hereafter concerning these sessions, and special programmes will be issued by the Local Committees of Philadelphia, Pittsburg, and the principal points to be visited in the subsequent general excursions.

The general excursion will proceed from Pittsburg to Chicago, and at the close of the visit to Chicago will divide into two parties, going respectively north and south. According to the programme of the General Reception Committee, the northern excursion will visit the Menominee, Gogebic and Marquette iron ranges and the Lake Superior copper district, returning to New York via the Sault Ste. Marie Canal, the Sudbury (Canada) nickel and copper mines and Niagara, while the southern excursion will go from Chicago to Birmingham, Shelby and Anniston, Ala., returning to New York via Chattanooga, Tenn., Middlesbrough, Roanoke, Cripple Creek iron mines and Pocahontas coal mines, Luray, Va., and Washington. Both excursions will reach New York about October 28th.

THE GRANT MONUMENT DESIGN.

The sub-committee of the Grant Monument Association have selected the design of John H. Duncan, architect, 237 Broadway, New York, and will recommend to the full committee that it be definitely and finally accepted as the design of the Grant Monument, subject to any change or alteration in the plan that may be suggested by the committee and the architect.

The design provides for a square structure, capped by a dome. At the base it is 100 feet square, and rises to a height of between 160 or 170 feet. The body is placed in a crypt which opens through into the first story of the structure. In the crypt there are to be places for two coffins. A porch comes out in front of the structure running up to which are a number of steps. This porch opens into the first story, which is really like a gallery encircling the dome, and from which it is possible to look down upon the coffin as it lies in the crypt. In the exterior and in the character of the ornamentation the structure has been treated after the manner of the Grecian style of architecture. The material out of which the structure is to be built lies entirely with the committee. The drawings were made to allow the cost to fall within the limit of $500,000, the figure set by the committee.

FLOATING THE OHIO CONNECTING RAILWAY CHANNEL SPAN.

We begin in this issue the publication of illustrations relating to the noteworthy engineering feat, so successfully accomplished last month, of floating into position the channel span of the Ohio Connecting Railway.

In our issue of August 23 we gave a description of the construction of this channel span of the Brunot's Island bridge across the Ohio River, near Pittsburg, Pa., and the remarkable features of its bodily transfer, several hundred feet, and high in the air, floating, on barges, from the pile foundation on which it was erected to its permanent position on the lofty piers. Since then we have received photographs that show the different stages of the work, and represent it sucessively, as it was erected, lifted up, floated up stream, and finally deposited on its piers.

The span has a total length of 523 feet, a depth of 65 feet, and a width of 25 feet. Its upper members are about 150 feet above low water, as stated on page 178, from which we substantially reprint the following account of the work.

The principal waterway is underneath the span, and to avoid obstructing the large and constant traffic, which includes many unwieldy tows of rafts and barges, as well as to be somewhat less exposed to danger from flood, it was decided not to build any false work, trestles or piling whatever between the piers, but instead to assemble the span at the required level, with its axis perpendicular to the final position and far enough removed to be clear of the main waterway.

In the shallow water along the shore of the island piles were driven in an area of about 100x600 feet, the short side of the rectangle being about parallel to the line of the bridge and 300 feet below it at the upper end. Each row was cut off and capped about 13½ feet above normal water level, and several lines of 20-inch steel I beams were laid across the caps. These formed stringers on which timber trestle bents, 54 feet high and 90 feet wide at the bottom, and 30 feet at the top, were erected and secured by wooden bracing and special adjustable iron tie rods.

On this false work the iron and steel bridge members were hoisted, assembled and connected, as shown in Fig. 1. Nine specially constructed barges were then floated into position under the 20-inch steel beams and between the rows of piles. The barges were 130'x25'x8' deep, strengthened by longitudinal and transverse bulkheads, and contained inlet valves through the bottom of every chamber. These valves were opened and the barges partially submerged.

Suitable framing was erected on the barges underneath, and nearly up to the steel beams. The valves were closed, and on August 18 the water was pumped out in about five hours by steam pumps on three adjacent tug boats, and as the barges rose they finally received the entire weight of the bridge span and supporting false work and floated it clear above the piles.

The false work was securely connected and braced to the barges, which were connected together by stringers in front and longitudinal bracing, and temporarily bolted with iron plates to the piles, and the span was secured against overturning by heavy steel guy ropes from each end of each barge. One flat boat was fastened to the bows of the last three barges, at each end of the line; together they were equipped with four hoisting engines which operated about 60,000 feet of towing tackle. The lines were run to the piers and to both shores. On the land side they were attached to the piles on which the false work originally rested.

On the afternoon of Monday, August 18, everything was in readiness to begin the work of moving. Blocking was placed between the I beams and the caps of the piles and the structure held in this condition through the night, and on the morning of August 19 guy ropes were attached to the floating mass, the barges disconnected from the piles, and at 8.50 A. M. the hoisting engines, winding upon tackles made fast to the shore, slowly drew out the barges until, at 11.15 A. M., the structure, including the boats, was clear of the piles. Stringers were placed across the rear of the barges and extra braces where the piles had previously interfered. Figure 2 is an end view of the bridge and trestle as erected and still supported on the piles, but with one barge B floated into position. Figure 3 shows the barges all in position and supporting the structure, which has been swung clear of the piles.

(Continued from page 226.)

The line of barges, 500 feet long, with its topheavy burden, nearly 1,000 tons of which was from 100 to 150 feet above the water, was then moved out like a unit and swung about one end as a center through a quarter circle, until it was parallel with the line of the bridge, towards which it was steadily drawn, as shown in the illustration on page 227. This was prepared from a photograph, taken at a point below the floating mass, as its engines drew it up stream against the current, and through wind and frequent rain, until it arrived between the piers. These had about 25 feet clearance from the end barges. Two heavy rainstorms interfered with progress in the afternoon. There was, however, not very much wind. The movement was slow, owing to the many lines, the number of shifts that had to be made, and the distance apart of the men, and was always in very short stages, preceded by careful adjustment of the guy lines. The span was thus brought approximately to position over its seats, about 26 inches above the pier at the fixed end and about 24 inches at the roller end. Guide bolts were passed through the shoes and inserted in holes prepared in the masonry, and at 7.30 P. M. the valves in the barges were opened and the false work gradually sunk until, at 8.20 P. M., the span was 10 inches and 8 inches clear of piers at the fixed and roller ends, respectively. It was then concluded to discontinue work. Wooden blocking was therefore put under for the night, and the span made fast to the piers by means of lines.

The structure remained in this condition with the boats under the span through the night. At 7.30 the next morning the span had been lowered so as to rest entirely upon the piers, as shown in Fig. 4. In this the trestles and barges, though no longer supporting the span, still remain just beneath it, and a line of barges, like a boom, is seen stretched across from pier to pier in front of them. The total weight moved by the barges was about 1,800 tons, 915 of which was the weight of the permanent span.

The bridge site is near the head of a "riffle," and the normal current is very swift there, but was, at the time of bridge launching, reduced to an estimated velocity of three miles an hour by closing the wickets of the United States Government dam across the river at Davis Island, a few miles below. The conditions were mainly favorable to the movement of the bridge, which satisfactorily fitted the seats prepared for it on top of the piers.

Later in the day, the boats with false works were removed from under the span and taken to the original position. The work of shortening up the false works was then begun.

As soon as the piles had been driven for the 416-foot span of the same bridge, the false works were to be floated down stream, around the point of the island, and towed into place in the other channel. They were then to be lowered on the piles and the boats removed. The erection of this span was then to be done in the usual way.

Freshets in the Ohio River interfered with this work, as the level of the river was raised above pool stage, and the Davis Island Dam was let down. Owing to this delay, this work could only recently be done. The false works are now resting on the piles in the 416-foot span, and the work of raising this span will be begun in a few days.

While the work of moving the false works around the island was under way, a violent gale of wind sprang up. A steamboat was used to tow the structure, assisted by lines running to the shores. When it was found that the steamboat would not hold the structure unassisted, the barges were allowed to drift against the shore, and the structure held in that position until the storm was over.

Large spans over the Hawkesbury River, Australia, the St. Lawrence River, the Missouri River, and perhaps elsewhere, have been erected in a somewhat similar manner by the use of floating false work, but so far as we remember, none of them were as long as this span, nor was the false work for them built on piles and afterwards transferred to barges, but was originally constructed on them. The Keystone Bridge Company, of Pittsburg, are the contractors for the building and erection of the Ohio connecting railway bridge. C. L. Strobel is the Chief Engineer of the Keystone Bridge Company, Max J. Becker, Chief Engineer of the Ohio Connecting Railway Company, and George R. Buchan is Superintendent of Outside Construction for the Keystone Bridge Company.

We hope soon to publish detailed descriptions and illustrations, that are now being prepared, of the superstructure of this bridge, and the false work, traveler, barges and general erection plant.

AIR VESSELS ON PIPES AND PUMPS.

FOLLOWING the queries in regard to "Air Cushions on a Water Main," and the replies to them which were published in our issues of May 24 and June 7, the subjoined practical paper on the same subject will be found of timely interest. It was read by Dugald Baird, manager of the Leven Collieries, Fifeshire, and read at a meeting of the Mining Institute of Scotland. The illustrations have been reproduced from London *Engineering*, in which the paper was published.

It is noteworthy that while the author says, when speaking of the position of air vessels, that a number of them might be fixed on an extra long discharge column or force main, that in the single instance mentioned by him, in case No. 3, where there was a large air vessel placed on a discharge column about half way up, it seems to have had little or no effect. This corroborates the opinion expressed on page 394 of Vol. XXI., that it is of comparatively little use to put air vessels on a force main, and that the only proper place for them is at the pump.

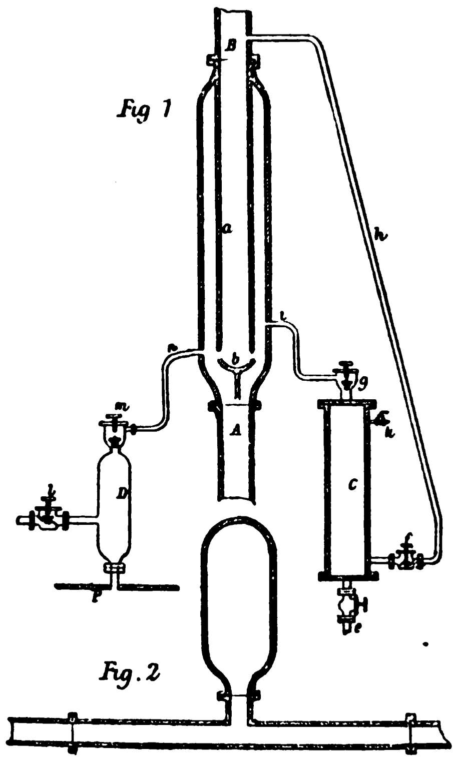
During the past six years I have had an excellent opportunity of studying the action of various kinds of pumping machines under many varying conditions, and, for the purpose of ascertaining the exact pressures and strains inside the pumps and pipes, my employer asked me to register these from time to time, and to do so a large number of diagrams were taken of steam cylinders, pumps, and pipes, and it is from these that the observations are based.

We have had during the time mentioned 35 different pumps at work, and have at the present time 27. Twenty-one of these are in operation night and day, and six are ready to start at a moment's notice. Their capacity varies from 40 gallons per minute up to 1,200 gallons per minute, and our total output in ordinary weather is 3,000 gallons per minute. From the notes kept of the working of these pumps we are satisfied that the air vessel plays a most important part in the working of pumps, and I propose to give the results of these inquiries and the conclusions come to based upon them.

1. Kelty No. 1 Pit. A 12-inch combined plunger and bucket Dook pump, where the motion was given by means of wooden rods. The bucket and ram had a velocity of 100 feet per minute, and the water in the discharge pipes had a velocity of 144 feet per minute. The length of the column was 200 yards, and had a vertical height of 28 fathoms. There was an air vessel on this column, but it was fixed on the side of the pipes and so could not trap the air that came up with the water, and there was no means of charging applied. This pump nearly always worked roughly and the wooden rods were often broken; the spurwheel of the engine also snapped and was renewed by a steel one, and three strong clack-pieces were burst. It was ultimately suggested that perhaps the air vessel was not doing its duty, and, having no other method, the oversman ran off the column. This was found to do a great deal of good as it caused the pump to go very much easier; and he also found that this had to be done every third day, and that, if he allowed it go longer, the pump began to work roughly, as before. It was a clear case of all the air that was in the air vessel escaping away with the water, and the pump, being left without a cushion for the shock caused by the high velocity of the water, went roughly. This arrangement of running off the column was carried out until the pump was no longer required, and there is no doubt that it prevented a large number of breakages. No diagrams were taken of this pump, but from a pressure gauge put on the pipes the pressure was seen to be three times the statical pressure when the air vessel was not acting. After this it was thought desirable to procure diagrams, which would show the pressure at different parts of the stroke, and M'Naught's engine indicator was used for the purpose, with good results.

2. The second case was that of the same class of Dook pump. At Pirnie a 10-inch combined bucket and ram pump had a velocity of 96 feet per minute, while the water had a velocity of 192 feet per minute; the column was 200 yards long and had a vertical height of 15 fathoms. There was an air vessel attached to this pump, which was charged by means of an air cock on the suction pipes, and the whole arrangement worked very well until the growth of water got too great for the pump going at a proper speed, and by-and-by the air cock got drowned. After a day or two the air evidently got exhausted from the air vessel, and heavy shocks came on to the pump and pipes and could be heard and felt even at the delivery end of the pipes. Owing to this extra pressure on the bucket the pump did not pump so much water, and before the cause was detected and a remedy thought of the pump itself was covered with water, and it looked as if the pump would be lost. A hole was, however, bored into the barrel, and this hole was tapped and a piece of pipe long enough to be above the water was screwed into it. On the end of this pipe a self-acting valve, which admitted air but shut during the back stroke, was fixed, and in ten minutes the pump was going as smoothly as ever it did, and mastered the water. Diagrams were taken of this pump, and show most distinctly the benefit of the air vessel when filled with air. With the air vessel the greatest pressure registered was 48 pounds per square inch, while without the air vessel the greatest pressure was 90 pounds per square inch, the statical pressure being 38 pounds per square inch. These diagrams are shown on Figs. 3 and 4.

3. This case was that of a 10-inch double-acting plunger pump going at 54 feet per minute, with the water in the pipes flowing at 150 feet per minute. The statical pressure was 104 pounds per square inch. The air vessel in this case could not be placed nearer than 20 feet from the first discharge clack and 35 feet from the other, and still with such a slow speed of pump and such a great distance from the clacks the highest pressure without the air vessel was 55 pounds per square inch greater than with it. The diagrams are shown on Figs. 5 and 6. The column of this pump is 480 yards long and has a vertical height of 40 fathoms. There is also another large air vessel fixed on the discharge column about midway up. This second air vessel was in working order when both No. 5 and No. 6 diagrams were taken. An air vessel is also attached to the suction pipes of this pump, and the same diagrams show the benefit of having an air vessel on the suction pipes, especially where they are long or small in diameter, or where the pump has to lift its water a great vertical height, or where the ram is moving very fast. In the case referred to the suction pipes are only 1 inch less than the ram; the height of them 100 feet. The vertical height the water is lifted is 15 feet. Figure 5 shows the pressure without the air vessel to vary from 8 pounds to nothing below atmosphere, whereas No. 6 shows that the pressure with the air vessel on only varies from 9½ pounds to 9 pounds below atmosphere, and as a consequence of the steady suction the pump is able to pump more water. It was found that after this air vessel was put on to the suction the pump could keep out the growth of water with half a stroke less speed, being reduced from 6 strokes to 5½ per minute.



AIR VESSELS ON PIPES AND PUMPS

FIG. 2.

4. The diagram shown on Fig. 9 is taken from a Kelty 20-inch double-acting plunger pump, with a vertical head of 90 fathoms, and having a large air vessel, which could not be fixed nearer than 90 feet from the clacks. This diagram shows the extra pressure required to lift the valves or clacks. The other diagrams already mentioned do not show this, because the pressure necessary to push the water through the discharge pipes is greater than that required to lift the clack, and so the pressure inside the casing does not fall the moment the clack lifts as it does in this case. The statical pressure is 234 pounds per square inch. The pressure required to lift the clack is 300 pounds, but the moment the clack lid lifts the pressure falls down to 270 pounds, which is the pressure necessary to push the water up the column of pipes, which are 17 inches in diameter. At first there was no air vessel on this pump and there was great difficulty in keeping the joints tight between the rams, which were horizontal, and the delivery pipes, which were vertical. There was no diagram taken before the air vessel was put on, because up to that time we had no instrument but the M'Naught indicator which was insufficient to register these pressures. A hydraulic pressure gauge was, however, put on, and it was found that, although the statical pressure was only 234 pounds, the gauge registered regularly 400 pounds, and occasionally 600 pounds per square inch. The diagram, Fig. 9, taken with the hydraulic indicator sketched at Fig. 10, shows how great is the improvement with the air vessel. Fig. 12 shows the type of engine and pumps referred to in this case; and as I believe it is the only case of the combination of Davey's horizontal compound surface and underground engines in

one, it may be interesting to those who, like Mr. Carlow, whose general design it was, do not like to risk a large engine at the bottom of the pit, where the growth of water is so heavy as to give little standage to prevent drowning in case of accident. The stroke is 7 feet, cylinders 42 inches, and 66 inches in diameter; steam pressure 65 pounds, diameter of ram 20 inches. The bell cranks work 17-inch and 15-inch buckets from the lower seams, which are 20 fathoms and 40 fathoms distant, respectively. The arrangement is found to work very satisfactorily. Before the air vessel was put on the level of the water in the column at the delivery end never fell below the level of the delivery pipe; but since it was put on the water dances up and down the pipes from 3 feet to 5 feet every alternate stroke, having the appearance of a column of water resting on a spring. When it was first put on it was found that this vibration took place, but every day the vibration grew less, until at the end of a week there was no vibration at all. This was owing to the air in the air vessel getting exhausted, the cause of which was a dip in the delivery pipe *a*, Fig. 12. A separate air pipe *b* was found to keep the air vessel always charged, the air being being got either from any leak in the ram stuffing boxes, or when the engine was going on air, or by a small cock on the suction pipes for the purpose when going solid continuously for some days.

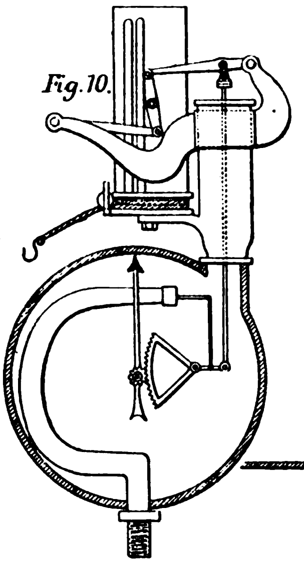

Fig 11.

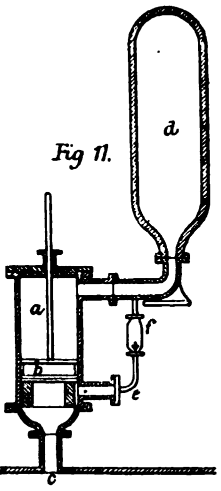

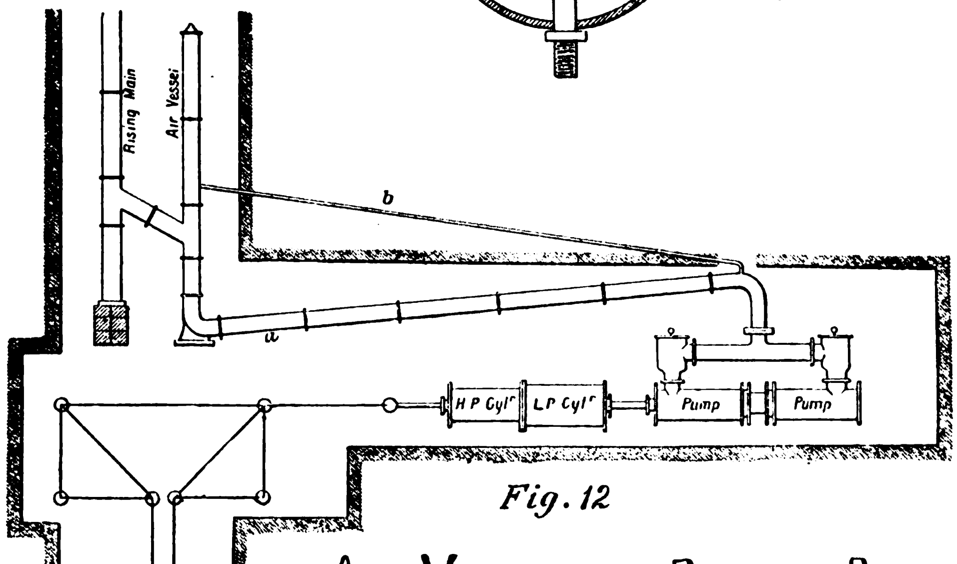

Fig. 12

As already mentioned, Fig. 10 shows the hydraulic indicator used for taking the diagrams under high pressures. It had to be made specially to order by Schäffer & Budenburg, as all our efforts at finding such an instrument were without success. It is simply the usual arrangement for fixing the paper, and the pencil for marking it, as in the Richards indicator, with a hydraulic pressure gauge attached to indicate up to 3,000 pounds per square inch. The mode of attachment will be readily followed from the sketch.

5. The diagrams shown in Figs. 7 and 8 are taken from the ram casing of the surface pump of a Moore hydraulic pump, and show a reduced maximum pressure with a piston air vessel as against its working without an air vessel. This pump is worked by a beam condensing rotary engine, geared 4 to 1, and it was found that the momentum of the flywheel carried on the rams and caused shocks which with a direct-acting Davey engine would not have occurred. It was to relieve the pump from these abnormal shocks that the air vessel was put on, which it does to a great extent when properly charged.

Air vessels to be of any use must be kept constantly charged with air; and, while there are many ways of charging them, there are five which I would recommend, partly from actual experience and partly suggested from that experience: 1, running off the column of water; 2, by means of a pet cock on the suction; 3, by the system shown on Fig. 1, at C; 4, by the system shown on Fig. 1, at D; 5, by means of a small air pump.

The first method is certainly a very clumsy one, but it is, nevertheless, often used. It also makes it necessary to have an air vessel of great capacity, seeing that with a heavy head the air is compressed into such small volume. For example: with a head of 100 fathoms, the air, after the column is full, if let in at atmosphere pressure, would only occupy one-eighteenth of the volume of the air vessel; or, in other words, if the air vessel was 18 feet long, the air would only occupy one foot at the top, which is not sufficient to be effective, unless the sectional area is all the greater.

The second method of charging is a most convenient and effective plan, and, except when the head is over 100 fathoms vertical, is found to serve the purpose well. The air is drawn in in small quantities; either at the pet cock on the suction or at the suction holes of the rattlehead, also any air sucked in at the packing glands is caught. The air passes right through the pump casing and valves, and when the air vessel is fixed in the correct place the air is trapped into it. The objection to this mode is that the pump draws a fraction less water, and the ram or bucket is apt to jump at the beginning of the stroke should there be more than a very small quantity of air in the casing at any one time. This tendency, of course, increases with the vertical height pumped; but I have seen this plan adopted on pumps having 15, 20, 40, 90, and 100 fathoms of vertical head with good results.

Refer to Fig. 1, at C, for the third method. We have there a separate pipe or chamber C, fitted with a common stop-cock *e*, a self-acting inlet valve *f*, a self-acting outlet valve *g*, with the pipe *h* from the column, and the pipe *i* to the air vessel, also an air cock *k*. To give the air vessel one charge of air the following is the process adopted: Shut *f*, open *e* and *k*, and, as soon as the water in C is all run off and C full of air, shut *k* and *e* and open *f*, the water from the column *b* will then enter C, and send all the air out into the air vessel through *g* and *i*. This process must be repeated as often as is necessary. The objection to this process is that it is not automatic, and requires to be done by the man in charge.

The process as shown at D, Fig. 1, is, I consider, the best under all circumstances. The apparatus consists of a small chamber D, a self-acting air valve *l*, opening inwards, a self-acting outlet valve *m*, and a pipe *n*, which leads the air into the air vessel. The chamber D is either fixed direct on to the pump casing *p*, or a pipe may be led from D to *p*, and thus D can be placed in any convenient position out of the way. The valve *l* opens automatically during the suction stroke of the pump, a small quantity of air is thereby drawn into D, and during the forcing stroke of the pump that air is expelled from D through *m* and *n* into the air vessel, and the same takes place every stroke that the pump makes.

The last method is by means of a small air pump, either worked by hand, or, which is much better, by some moving part of the pump. This action is familiar to every one and need not be described.

I will now offer the following observations which readily are suggested by what has been already said. Every pump which has the ram or bucket moving at a greater velocity than 40 feet per minute, and has the area of the pipes not larger than the ram or bucket, will work more smoothly with an air vessel than without one.

Regarding the position of the air vessel, the nearer it is to the casing or barrel the better. If only one is used it should be placed immediately above the discharge clack—that is, on the delivery side of it. Then if the column be extra long, as in pumping up an incline or any other road where a long discharge column is required, a number of air vessels might be fixed; but the number of these and the distance apart will necessarily depend on the velocity of the water inside the pipes. It is quite evident that if a long distance intervenes between the ram or bucket and the air vessel, the shocks which have their origin in the casing or barrel will not be so readily relieved by the air vessel as if a short space intervened; because there will be a greater body of water to move, the inertia of which will be sufficient to create a considerable pressure, though by no means so great as there would be if no air vessel was there at all, unless we imagine some extreme case, as a pump getting suddenly totally fast at the foot, and dropping full stroke, when, of course, nothing could save the casing or barrel. If these conditions presented themselves to a moderate extent I believe a piston air vessel, as shown in Fig. 11, would be of good service. Its action will be described further on.

It is also of vital importance to place the air vessel in such a position that a regular supply of air may find its way into it and thereby replace the air that leaks away with the water, else a few days will be long enough to totally exhaust the air and leave the action of the air vessel *nil*.

The best form of an air vessel for a vertical column is that shown on Fig. 1 at A B, where it can be charged naturally or otherwise. The rising column A B is increased in diameter and an inside pipe A brought down near to the bottom of the chamber, where is fixed a cup *b*, which diverts all the particles of air flowing with the water into the chamber. The simplest way to fix an air vessel on to a horizontal line of pipes is, as shown in Fig. 2, exactly on the top side of the pipes.

Figure 11 shows a piston air vessel, the same principle as that on our Moore's hydraulic surface power pump, but drawn so as to show its applicability to a single-acting pump. I consider it could be placed with much advantage on the casing or barrel of a plunger or bucket pump. It consists of a cylinder *a* in which is a piston *b*, which has direct communication on the underside with the casing or barrel *c*, and on the top side with the air vessel *d*. There is a connecting pipe *e* from below the piston to the top of the piston and in this is fixed a self-acting valve *f*. This valve is constructed with a spiral spring on the top of it, so that it can be screwed down or eased off, so as to give the required pressure in the air vessel. If the normal pressure in the air vessel is required at, say 300 pounds, this valve will be screwed down so that it will not pass any water unless the pressure in the air vessel becomes less than 300 from leakage at the piston, the pressure in the air vessel will thereby be sustained. It is also necessary to attach an air charger on this air vessel, but the leakage of air is very slight. This piston air vessel will act exactly the same as an ordinary one—that is, it will give and take each stroke of the pump and has the great advantage of being close up to the place where, with few exceptions, all the shocks have their origin, that is, between the suction and discharge valves.

Regarding the capacity of an air vessel, I have made no investigations. The air vessel on the Kelty pump shown in Fig. 12, and from which the diagram shown in Fig. 9 was taken, is four times greater than the volume of the ram. The one on the Pernie pump, the diagrams of which are shown in Figs. 3 and 4, is three times that of the ram. The one on the Pernie pump, the diagrams of which are shown in Figs. 5 and 6, is twice that of the ram, the suction air vessel three-quarters that of the ram, and the piston air vessel twice that of the ram. I think, however, that no air vessel should be of less than four times the capacity of the ram or bucket.

WAVE MOTOR AT OCEAN GROVE, N. J.

The new wave motor in operation at Ocean Grove, N. J., during the season just closing, has been an object of interest to many visitors, and differs wholly in design from that erected last year. The latter consisted of a thick wooden blade, strongly built, and measuring about 5 feet wide by 8 feet long. The blade was hung from pivots at its upper corners between two piles of a dock, and was free to be swung to and fro by the waves. Projecting from the upper edge was a rod, so connected as to operate a pump which elevated salt water to a tank, from which it was delivered to carts for sprinkling the streets.

The new motor depends for its action upon the rise and fall of a float acted upon by the waves. A frame, pivoted at one end, between piles, carries at its other end a float, from which a wire rope extends over a set of sheaves having a weight secured to it. Attached to this rope is a second one passing over another sheave and operating the plunger of a pump, the water being delivered by an overhead tank. The float weighs 2,500 pounds, the weight at the end of the wire rope 2,000 pounds, and the tank has a capacity of 12,000 gallons. As the float rises on a wave, the counter-weight descends and lifts the pump plunger, which performs the return stroke by its own weight, as the counterbalance is lifted by the fall of the float. The pump has a bore of six inches and a stroke of six feet, and is single acting. Allowance is made for the rise and fall of the tide by changing the length of the rope leading from the weight to the plunger. Provision is made for lifting the float entirely out of the water when the waves are running unusually high.

A NEW GRINDING MATERIAL.

According to *The Engineering and Mining Journal*, crushed steel is said to be coming into use for cutting stone. It appears to be made by quenching very high carbon steel in cold water from an excessively high temperature, such as would overheat steel for most purposes. This renders it not only hard but rather brittle, so that it is possible to pulverize it; it is crushed in a stampmill, and sifted closely to size. It is said to be not only cheaper, but much more effective than emery, giving a better polish and quicker, and lasting much longer.

The tunneling of the Khojak Mountains marks an important step in advance in the project of building a railroad from the lower Indus Valley to Kandahar, in Afghanistan. The Khojak tunnel, though not yet completed as regards lining, is one of the longest in the world, having a length of 12,456 feet.

The Elmore Patent Copper Depositing Company (Limited), of London, England, are the makers of the electrically deposited copper pipes which, of late, have attracted so much attention. The pipes are made of any size up to 3 feet 4 inches in diameter and 10 feet long.

LOWERING A WATER MAIN AT PRINCETON.

A few months ago it became necessary to lower a water main at Princeton, N. J. The size of the main was 10 inches, and it was lowered, for a distance of 650 feet, from 2 feet 8 inches in the center of the trench, to nothing at the ends, so as to keep 4 feet of earth over it after the grade of the road was straightened at that point.

The method of lowering is shown in Fig. 1. After the pipe was uncovered, a short piece of chain was passed around it in front of each joint, and the ends were brought up and hooked over the lower end of a long screw, which was bent up so as to form a hook.

These screws passed through pieces of timber, placed across the trench, and each of them had a nut with a long handle, by means of which it could be raised or lowered. After the pipes were thus supported, the trench was excavated below them to the required depth, most of the weight of the pipes being taken on blocking, which was built up beneath them to keep them from swinging and to prevent injury from any accident to the chains or screws. In making this excavation much difficulty was experienced from an unexpected ledge of rock, which had to be wedged and sledged out piecemeal, much increasing the time and cost of the work. As shown in the sketch, the trench was wider on one side of the pipes than the other, for convenience of excavation, the total width being about 3½ feet.

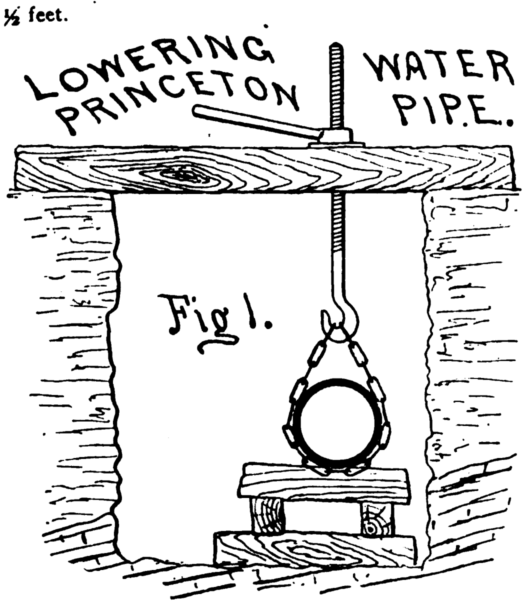

Fig 1.

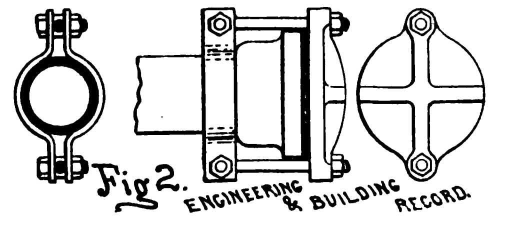

Fig 2.

When everything was ready, a number of men, unwinding the nuts at a speed roughly proportioned to the depth the pipe had to be lowered at each point, gradually settled the pipe to its bed, the blocking being removed as it went down. The pipe thus lowered was the supply main from the stand-pipe to the distributing system, and it was the intention to have lowered it without taking off the pressure, usually about 70 pounds. With that object in view two 4-inch branches were capped, as shown in Fig. 2, and the house services were temporarily connected by short lengths of hose. To keep the pressure on, however, would have involved the simultaneous lowering of an adjacent hydrant and gate, connected by a short branch, and it was finally concluded to take the pressure off the main while lowering, the town being meantime supplied through a 4-inch by-pass.

The pipes were of the usual length, 12 feet each, and were estimated to weigh, with the contained water, 1,100 pounds apiece. The chain was of ⅜-inch iron, made with long links for convenience of hooking on. This would give a stress of at least 2,500 pounds per square inch, and in view of the probability that the rigidity of the joints might cause an unequal distribution of the load, it was thought by those in charge that a ½-inch chain would have been better, although no accident occurred. The screws were 1 inch in diameter and from 1½ to 4½ feet long, and the length of the handle on the nut was 18 inches.

The cost of the work was as follows: 362 feet of chain, $33.80; 40 screws, $42.53; 2 caps for 4-inch pipe, $10.27; lumber, $4.08; total for material, $90.68. Excavating and back filling, $365.51; carting timber, blocking tools, etc., $15; night watch, $34; sharpening tools, etc., $2.65; total for labor, $417.16. To this must be added $5.10 for incidental expenses, and $16.45 for building a manhole (4.50 per mason and $11.95 for brick and cement), bringing the total cost up to $529.39. The blocking was borrowed for the occasion and so cost nothing. The whole operation was planned and successfully carried out by James E. Burke Superintendent of the Princeton Water Company, and Martin Bergen, Chief Engineer of the pumping station.

The 4-inch pipe closer, shown in Fig. 2, consisted of a rubber gasket 8½ inches in diameter and half an inch thick, supported by a ribbed cast-iron plate, drawn up by two ¾-inch bolts, having eyes formed in one end through which passed two other short bolts. These united the two halves of a collar of 2 by ⅜-inch iron which embraced the pipe just below the hub. It answered its purpose very well.

AN EXPERIENCE IN THE CONSTRUCTION OF A GAS-HOLDER TANK.

In a paper on gas-holder tank construction, recently read before the Engineers' Club, of Cleveland, O., and published in the *Journal* of the Association of Engineering Societies, G. A. Hyde gives the following data:

In 1872 he was called to construct a gas-holder tank for the Titusville Gas Company, at Titusville, Pa., under the particular and unusual condition of superabundance of water in the earth. The location was a level piece of ground in the valley adjacent to a creek and the excavation coarse gravel and small boulders. The excavation was made 12 feet below surface of ground, 6 feet of which was below the bed of the creek. To make the excavation and construct the tank wall it was necessary to raise 8,000 to 10,000 barrels of water per day. The method of procedure to accomplish that end was as follows: A well was sunk outside of the space to be occupied by the tank and to a depth sufficient to drain the earth below the required depth of the tank wall. After the excavation had been made to grade of the bottom of the footing a ditch was dug outside of the line of footing deep enough to receive a line of sewer pipe ranging in size from 10 inches to 4 inches in diameter, running both ways from the well to the opposite side of the tank. The joints were left open to permit the free access of the water from the gravel. Then followed the laying of the footing and the building of the tank wall, during which time the pump was kept in constant operation.

A 10-inch iron pipe was laid under the footing at a point opposite the well, through which to convey the water collected on the inside of the tank wall. Another row of sewer pipes, ranging in diameter from 10 inches to 4 inches, was laid along below and near the inner line of the footing, and connected to the iron pipe leading to the well. From a few points inside of the tank, where abundant springs appeared, a line of 4 inch sewer pipe was laid to the larger sewer pipe, by which means all water appearing was safely and surely conveyed to the pump-well.

The whole surface of the bottom of the tank was then covered with cement concrete to the depth of 8 inches, but leaving a vent hole 10 inches in diameter at the junction of the sewer pipes and the iron pipe, to permit the inflow of water into the tank in the event of the stopping of the pumps, and the outflow of the water from the well.

When the concrete was completed and properly set the holder was built, and then a plate was secured to the vent hole and covered with cement mortar. The water from the pump was then turned into the tank until filled to the top, completing the undertaking.

Experiments are being made by the Delaware and Hudson Railroad Company to test the adaptability and superiority of steel ties for railroad uses. On a section of the road leading south of Ballston, N. Y., for nearly half a mile, the wooden sleepers have been removed and the track reconstructed with the steel ties. The test of the safety and adaptability of the steel ties is being made under the supervision of A. J. Swift, chief engineer of the road, and they will be adopted or rejected upon his recommendation.

WORK ON THE NICARAGUA CANAL.

A **Washington** dispatch states that A. J. Menocal and several other gentlemen of the engineering staff of the Nicaragua Canal construction corps have just reached Washington from Greytown on a short leave of absence. They report commendable progress already on the great engineering project. Several million dollars have already been spent and the active work of canal construction is now well under way.

The actual dredging for the canal on the gulf side has begun. The telegraph line from Greytown to Lake Nicaragua, connecting with the lines on the Pacific coast, is completed and the railroad from Greytown to the lake along the line of the canal is well under way.

At present about 1,800 men and a corps of 80 engineers are on the ground and at work. The work preliminary to work on the canal proper was the building of the great pier at Greytown, extending 1.800 feet out toward the deep water. This pier is necessary to protect the entrance to the canal and work on it was begun early last January. Seven hundred feet of the pier has been completed. This pier has proved a lucky enterprise. When work was begun on it the entrance to the harbor was obstructed by a sandbar. The 700 feet of pier already built has so changed the current that this obstructing sandbar has been almost entirely worn away by the action of the water.

VITRIFIED PIPE FOR SEWERS.

In an address on the sewerage of Columbus, O., delivered at the Columbus Board of Trade Auditorium a short time ago, Col. George E. Waring, Jr., said, in discussing the plans for a proposed new intercepting sewer:

"The specifications call for the building of the upper end of the sewer, where it is 24 inches in diameter, with 24-inch pipe. I have myself recommended frequently, in years past, the use of vitrified pipe of as large a diameter as 24 inches. I shall never do it again. Those pipes are not reliable, and I do not know to-day of a 24-inch sewer, nor a 20-inch sewer, nor an 18-inch sewer constructed in that way that I should consider reliable. The material is not a safe one to use in these large diameters, and I shall hereafter use nothing larger than 15 inches. Everything beyond that I shall make either of concrete or of brick work. * * *

"I noticed also that it is provided in the specifications and in the contract that, where the sewer is 3 feet in diameter, it shall be built, as we say, of two rings; that is, that it shall be 8 inches, and a streak of mortar thick, instead of 4 inches. It seems to me that this is a waste of material, and will fail to secure the best results. There is no reason why a 36-inch sewer may not be made of a single ring of brick. Any engineer, contractor or inspector attempting to build a sewer of a single ring, will be very sure to have a good quality of brick, good cement, and good workmanship; whereas, if he is allowed to use two rings, he may put in anything he likes, expecting that the mere bulk of material will carry him through.

"I have had a good deal of experience with sewers of that size, with both 8-inch walls and 4-inch walls, and in my opinion the 4-inch walls are stronger, the joints tighter, the material harder, and the friction of the stream has a great deal less effect in washing out the mortar and leaving it rough, because the mortar is better. I therefore recommend that so far as the sewer is 3 feet in diameter, it be reduced from the double ring to the single ring."

We shall be glad to learn the experience of other of our readers who have used large sized vitrified pipes for sewers.

With regard to the number of courses of brick in a 36-inch sewer we should say the character of the soil should determine that.

According to a Washington dispatch, the Commerce Committee of the House has agreed to a favorable report on the bill introduced by Representative John M. Wiley authorizing the construction of a bridge across the Hudson from Manhattan Island to the New Jersey shore. The bridge has received the sanction of the Legislatures of both States. The bill provides that the structure shall be erected not above Fifty-ninth Street, New York.

Secretary Buchholz, of the Board of Experts of the Brooklyn Bridge, sent out notices recently that the time for the reception of plans for increased terminal facilities would be extended twenty days from September 1. The reason for this is that very few plans have been received.

The 110-ton traveling crane at the gun shops at Washington, D. C., is said to be the largest in the world. Including the frame work on which the crane rests, the cost amounted to $100,000.

THE RIGHTS OF STREET CAR COMPANIES AND OF LOCAL AUTHORITIES.

The relative powers of street car companies and local authorities in those districts traversed by the car lines, so far as the power over the maintenance and construction of the road is concerned, has recently been settled in England in the Court of Appeal, in connection with the Bristol Tramway Company on the one hand and the Corporation on the other. The Tramway Company when laying the lines originally laid between the metals, and to a width of one and a half feet on each side, granite sets, the roadways at that time being to a large extent macadam. The Corporation, having determined later to adopt a system of wood paving, called upon the car company to substitute wood for the granite at their own expense. This demand was subsequently withdrawn, the Corporation announcing their intention of laying down the wood themselves throughout. To this determination the car company took exception, averring that in the Tramways Act of 1870 they had certain rights as to the roads with the power of appealing to the Board of Trade for arbitration. They accordingly obtained an injunction against the Corporation, restraining them from making any change pending such an appeal to the Board of Trade. The Corporation took the question to the Court of Appeal, and obtained judgment on the ground that the powers of reference enjoyed by the various car companies to the Board of Trade did not embrace those of authority over the roadways traversed by their lines. The court called attention to the fact that the act expressly stated that local authorities should not be interfered with so far as their powers of alteration or improvement of the roads was concerned and that the rights of the car companies were limited simply to the question of user.

PETROLEUM ENGINES FOR LIGHTHOUSES.

An interesting application of the Priestman petroleum engine has just been made at the Corsewall Lighthouse, Firth of Clyde, Scotland, where Mr. D. A. Stevenson, the engineer to the Commissioners of Northern Lighthouses, has adopted this motor for working the fog signal apparatus which has just been erected there. The signal, according to *Engineering*, is produced by a siren, and it is to supply compressed air for this that the Priestman engine has been adopted. From the circumstances of the case, steam could not be used, and hot-air engines so frequently used in lighthouses are cumbrous, whilst if gas engines are used it is necessary to fit up a gas-distilling apparatus, which again takes up a good deal of room. The engines at Corsewall are three in number, and of five horse-power each. They use the same heavy petroleum that is used for lighthouse lamps, and hence there is no danger of an explosion occurring as there would if benzoline or naphtha was used. The engines, of which one is a reserve in case of a breakdown, drive a set of compressors through a helical gearing. The air is compressed, at a pressure of 40 pounds above the atmosphere, into the receivers from which the supply for the siren is taken.

BOOK NOTICES,

Academy Architecture and Annual Architectural Review, 1890. Published by Alex. Koch, architect. London, England. Price, $1.50.

The first appearance of Academy Architecture, last year, proved so successful that the London publishers concluded to issue also an American edition for this year. The little volume has just been brought out, and contains 108 pages, given up entirely to illustrations. These represent a selection of the most prominent architectural drawings hung at the Royal Academy Exhibition, and a review of interesting architectural subjects carried out, or designed, during the last few years. While the illustrations are, perhaps, not the most desirable specimens of the engraver's and reproducer's art, there can be little question that the matter presented will prove interesting and valuable to architects, draughtsmen, and designers, as well as to students and lovers of art generally.

The American edition is in the hands of William Mueller, 695 Broadway, New York.

Cleveland, O., claims the lead in the American shipbuilding industry on the lakes. Since January 1, 1890, the vessels built at the different points number 78 steamers, the gross tonnage being 63.922, and 18 barges and sailing ships of 15.315 tons. Last year the vessels built on the great lakes measured 107,080 tons.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

EXPERT ADVICE FOR ARCHITECTS.

New York, September 8, 1890.

To the Editor of The Engineering and Building Record:

Sir: In your issue of September 6, your article entitled "A Lesson For Architects," is very much to the point. Many architects must, however, open their eyes to existing practices, which are unprofessional and contrary to the interest of their employers—viz.: their selection of favorite contractors who will supplement the deficiencies of the architect on points of construction. Some of our architects are known to have their iron construction designed in this way. Can they make themselves believe that this work is done absolutely gratis? Do they not appreciate that their employer is paying an additional fee, hidden, of course, within the bid? Do they understand that such contractors are necessarily looking out for themselves far more than they are for the owner?

Is an architect doing his full professional duty when he thus delegates a large part of the design of his building to such parties? Only one conclusion can possibly be drawn from such a practice, and that is, the architect is not willing to sacrifice any portion of his fee to a consulting engineer, who would have no interests to serve but those of the architect and owner.

The results, as pointed out in your article, will never be obtained until architects realize that they must sacrifice some portion of their fees to competent engineers, or else, that they must frankly state to the owner that it would be greatly to his interest, in getting both better and more economical results, if he would allow an additional professional fee for the employment of competent engineers to advise upon the foundations, structural work, sanitation, etc., of the building under contemplation.

Consulting Engineer.

THE MIDDLESBOROUGH, KY., WATER-WORKS.

Middlesborough Water Company,
Middlesborough, Ky., September 7, 1890.

To the Editor of The Engineering and Building Record:

Sir: I don't know if you have ever received a prospectus of the "Marvelous City" of Middlesborough, Ky., or not. I therefore send you one by this mail, and as soon as the new one, that the association is getting out, is ready, I will forward one of them. About a year ago there were two or three houses in this valley, to-day there are hundreds. The residents are temporarily supplied with water from "Summitts Fork" through a 3-inch pipe by two Davidson No. 3 pumps, located about a mile from the city, pumping to tanks on Arthur Heights, about 100 feet above the main streets.

Work was commenced in July for quite an extensive system. A storage reservoir of some 400,000,000 gallons capacity will be formed by damming up Little Yellow Creek, located about a mile and a quarter from the center of the city, between the main Cumberland range and Mingo mountain. The dam will be of earth embankment with a core of solid masonry, 5 feet thick at flowage line, increasing in thickness to base, which will rest on rock bottom. The pumping station will contain one 6,000,000 vertical pumping engine, with space for others when required, and a 24-inch force main to 1,000,000 gallon tank on summit of Mingo mountain, 275 feet above plain of city.

Contract has been awarded to Anniston Pipe Works, of Anniston, Ala., for all 20 and 24-inch pipe (about 1,000 tons), and to the South Pittsburg Pipe Works, of South Pittsburg, Tenn., for all smaller sizes and all specials. The Cunningham Iron Works, of Boston, will construct the stand-pipe on Mingo Mountain. The city contracts for 50 fire hydrants, at $65 per annum for first 50; $60 for next 50, and $50 for all over 100. The meter system has been adopted, and the National Meter Company of New York, will furnish Crown meters. The Ludlow Valve Company has the contract to furnish all valves and hydrants. Pumps have not yet been ordered, as the engineer is not yet ready with plans. Professor Waller, of New York, has analyzed the water of Little Yellow Creek, and pronounces the quality excellent for domestic and manufacturing purposes. Work will be pushed as fast as possible, and it is expected that water will be turned on in July, 1891.

The dam will be started in a few days.

A. H. Martink,
Chief Engineer and Superintendent.

A **steep** cable railway has lately been built up the slopes of Monte San Salvatore, near the Lake of Lugano, Italy. The power for working is obtained from a stream in the vicinity, and is transmitted electrically to the operating station. The water is led through a long iron pipe to two Girard turbines coupled direct to Oerlikon dynamos. The road is about a mile long and has grades varying from 17 to 60 per cent.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department.* Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

FIRE STREAMS.

"G. S.," of Billings, Montana, writes: "How far can a fire stream be thrown under the following conditions? We have two 500,000-gallon pumps (a Dean and a Blake); suction to pumps is 12-inch pipe, 40 feet long; discharge is 8-inch pipe, 7,920 feet long; from 8-inch pipe to hydrant there are 2,240 feet of 4-inch pipe; from hydrant to end of nozzle there are 1,300 feet of hose, nozzle has 1-inch opening. What I want to know is this: How many pounds pressure ought there be at the nozzle when we have 160 pounds pressure at the pumps? Also, how long a stream had we ought to get when the nozzle is held at an angle of 45 degrees? We have four and a half miles of main pipe (Kalamein) with 160 taps (¾ and ½ inch), you can safely figure on one-quarter of them running all the time for sprinkling purposes."

[We know of no formula that could be applied to the above case with anything like satisfactory results. Most of the conditions entering the problem are of a decidedly variable character and cannot be properly taken into account in a calculation. We would refer our correspondent to a paper read by John R. Freeman some months ago before the American Society of Civil Engineers, and, also, in more condensed form before the New England Water-Works Association, in which an exhaustive account is given of experiments relating to fire streams. An abstract of the paper is given in THE ENGINEERING AND BUILDING RECORD, Vol. XXI., pages 71, 137, 183, 214, 325, and 340. Study of what was given of the paper in our columns will prove alike interesting and valuable to G. S.]

BOOKS ON FLUMES.

H. T. KOCH, of the Castle Creek Water Company, Aspen, Col., asks: "Have you any works treating of and describing flumes?"

[So far as we are aware there are no books treating solely of the subject of flumes. The literature of the subject is somewhat scattered in the shape of contributions to engineering societies, chiefly Western, and can be found in their transactions.]

STEEL FOR WATER AND OTHER PIPES.

REFERRING to the article entitled "Steel for Water and Other Pipes," published in our issue of August 2, 1890, The Steel Pipe Company, Limited, of Kirkcaldy, Scotland, write:

"We inclose herewith copy of a letter which we have sent to the Secretary of the American Water-Works Association, and shall be obliged if you will kindly send us any further particulars referring to the uses of steel for water, etc., which may come under your notice."

[The letter addressed to the American Water-Works Association reads as follows:

"We notice in THE ENGINEERING AND BUILDING RECORD of August 2 that reference is made to a discussion upon the uses of steel for water and other pipes, and we shall esteem it a favor if you will kindly send us a copy of the proceedings. We may mention that the managing directors of this company are the pioneers in Great Britain of this industry, and that the steel pipes referred to in the above article were made to the specifications and under the supervision of our managing directors, Messrs. A. & J. Stewart, and The Steel Company, of Scotland, Limited, being sub-contractors, and all the other pipe lines referred to were manufactured by us. This company is a new company organized to carry out steel pipe line contracts, and has been instrumental in introducing steel pipe lines to the British colonies, to South America, Africa, and nearly all countries in the world."]

FIVE years ago the electric light began to be used in Japan. Since then there has been a rapid development in electrical matters in that country, and the capacity of the present electric light stations is 22,300 lights.

DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

HEATING AND VENTILATING SCHOOL-HOUSES

(Concluded from page 220)

THE general arrangement for the location of a furnace is shown in Fig. 8. The furnace is placed in the basement, of course, and the flues, which are also shown in Figs. 9 and 10, are placed as near as possible to it, one of them going up to the first story, and the other to the second story, the one going to the second story being the smaller flue, because its greater height gives it a stronger draught power than the shorter one. These areas are about as two to three. One of the special features of this arrangement is this, that the whole space at the front end of the school building is a cold-air box, having three windows on as many sides opening into it, so that the furnace is virtually standing out of doors. It does away with the chief objections to the cold-air box, with its necessarily contracted area and its frictional resistance to flow and the retarding effect of bends, etc., for the access of air through the windows and large chambers is relatively free. These windows are arranged to provide against failure to secure air supply in the case of strong winds.

The exhaust aperture is at the floor, partly underneath and partly above the platform, on the same side with the air inlets. In Figs. 9 and 10 note the relative position of the supply and vent apertures. Manifestly, in such a room as this, with three cold sides, the warm air rising to and floating at the ceiling will be chilled by contact with the walls and windows and thrown down; it will then tend to move across the floor and away from the walls and in directions whose resultant point would be somewhere in front of the platform, and the vent opening might perhaps better be at that point, but convenience in construction and cleanliness also favor the location shown, and efficiency is practically unimpaired. The areas both of vent and of discharge are in all cases large.

The furnace pipe is made to pass around and up through the discharge shaft, as shown in Fig. 11. An 8-inch pipe is fitted to the furnace collar and that pipe is enlarged to a 10-inch within the flue in order to get a larger surface for heating the air in the flue, and also to secure a slower movement and longer retention of the hot gases through it. But there are times when a greater heat will be wanted than can be furnished by this pipe. When, in warm weather, the temperature of the furnace is lowest, we want the highest temperature in the vent flue, and by the arrangement thus far considered we get the reverse of what is actually needed. But if at such times the furnace heat not wanted in the rooms could be diverted into the ventilating flue the desired condition would be realized. The figure shows a 15-inch pipe connecting the ventilating shaft with the hot-air chamber of the furnace, and through which, by the opening of a damper, the heated air may be passed. So that when there is an excess of heat in the furnace for the requirements of warmth, it is possible to open up this damper to admit the heated air to the vent flue, the air passing from the furnace directly into that flue, and so giving the extra warmth required. To be sure, we are then passing fresh air into the flue and in so far displacing foul air, but Professor Woodbridge considers that a better method than putting a stove into the vent flue of a little school-house and trusting to the janitor, who visits the school but once or twice a day, to look after and keep up the fire, or even trusting to the teachers, who have something else to do than to poke fires and feed them with coal.

This vent flue, as well as those for supply, must, of course, be controlled in area. It is done by means of two dampers hinged as shown, and opened to requirement by cords passing over pulleys and brought as one down into the principal's room, with means for securing it at notches, which might be conveniently marked for 0°, 10°, 20°, etc., weather, as indicated by an outside thermometer.

Figure 12 shows a method of arranging the inlet windows so as to prevent loss of air. Ordinarily, if the air is blowing in through a chamber window strongly on one side, it will be, in part, passing out on the other, or leeward side, and to that extent will be lost. Therefore it is desirable to arrange the inlets so that in whichever way the wind blows, the desired quantity shall be passing into the room. Suppose a long, vertical box, covered with wire cloth, through which the air can easily pass, be placed before each window, and that over that wire netting light gossamer strips or valves are hung. With the least air pressure these are thrown out, letting the air in freely. Whenever the wind blows in through the window the valve is open and the air passes through, but the moment the wind takes the opposite direction these valves close. Therefore, if the air blows in strongly on one side it merely closes up all the valves on the other sides and keeps in the chamber all the air that would otherwise escape, and the influence is at once felt in the pressure produced on the furnace. In still weather the air will come in through all these windows gradually, slightly lifting the valves, and whenever the high wind would tend to disturb the action of the furnace, such action is prevented by the closing of the leeward valves.

One thing more in connection with this furnace. It has been said that when the air is warm outside but little heat is wanted in the furnace, and that it would better pass up the ventilating flue. In other words, very little heat is wanted from the furnace in warm weather, and in cold weather the total produced is wanted. It must be said that this furnace is not altogether what could be desired for the transfer of heat from the gases to the air. Although we have large area and intimacy of contact on the outside, we have not a correspondingly large area and provision for intimacy of contact on the inside. The combustion gases may pass off from this furnace pretty hot. What is wanted here is, of course, some means of transferring to the supply air that otherwise waste heat.

Figure 13 shows an arrangement proposed for this purpose. The direct and vertical pipe which goes into the vent flue has a damper which may be closed. The closing of this damper forces the hot gases to pass through the long trombone-formed pipe, shortened in the figure for want of space. The combustion gases make a tortuous course; the current is broken at each turn, and the conditions are favorable for a large transfer of the contained heat.

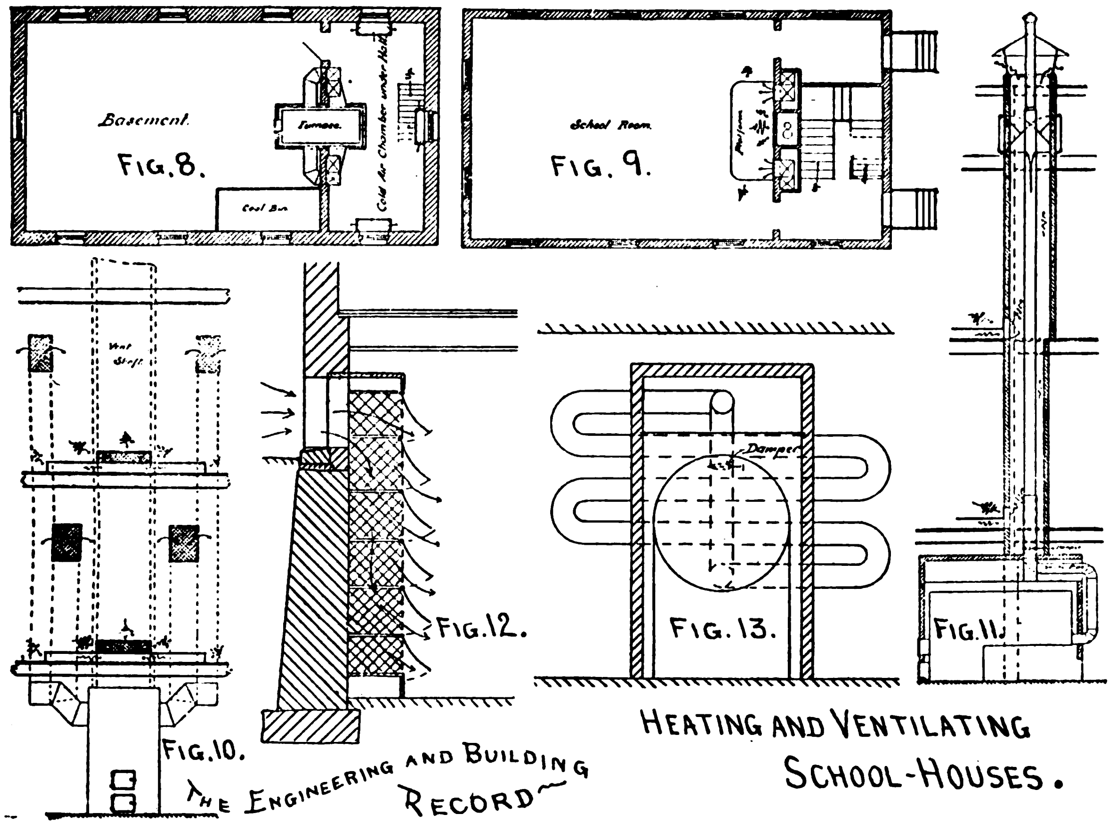
In the resulting discussion, Professor Woodbridge, speaking of the extension rings on the furnace, shown in Fig. 5, page 219, said that these rings are cast in one piece with the parts to which they belong, and are a part of the furnace itself; and these flanges becoming chilled tend to keep the shell to which they are attached much cooler than it would be without them, and the cooler the shell the more perfect the transfer of the heat of the gases inside of that shell; and, further, the effect gotten from so extended a surface moderately warmed is very much to be preferred to the same heat yielded to air by a small surface highly heated. There has been in no case observed any overheating of the air. The question is simply this: Given a certain amount of furnace shell surface exposed on its inside to combustion gases at fixed temperature, and on its outside to cooler air, by which of two ways will that shell transfer the heat most rapidly; by the contact of cool air with a plane outside surface, or by conduction through continuous metal kept cool by the movement of air over an extended surface?

When the extended surface is, in form and exposure, such as to allow as free a movement of air over it as would be had over the corresponding plane surface, the heat transfer is increased, and for these reasons: First, the transfer of heat by convection per unit of surface, varies directly as the temperature difference between that surface and the impinging air. Second, the rate of transfer of heat between two planes represented by one inch of continuous iron is 390 times that yielded by convection when the two planes have the same temperature difference as that existing between the air and the warmer surface. Hence, if the surface next the combustion gases is maintained at a fixed temperature, the temperature difference between an extended surface and the impinging air cannot vary inversely as the ratio of extension, but must be in considerable excess of the ratio, because of the rapid transfer of heat by conduction. Thus, if the temperature difference between the plane surface and the air were 300 degrees, by the extension of that surface to 12 areas, the temperature difference between it and the air would not drop to 25 degrees, but would be maintained at, say, 50 to 75 degrees.

If the objection is made that the rapid cooling of the furnace shell makes its fire-exposed temperature so low that the assumption on which the argument just made is based becomes untenable, that very objection contains all the argument desired in favor of extended surface, since the cooler the furnace shell the more rapid and complete must be the transfer of heat from the combustion gases to it, and from the shell to the air.

As to what happens to overheated air that comes in contact with red-hot iron, Professor Woodbridge continued that the amount of dust floating in the air, the purest air obtainable or found within our buildings, is much larger than is generally supposed. Not until a room is darkened and a sunbeam is "seen" by the reflection of its light from the dust in its path, do we begin to have any idea of the quantity of dust there may be and is in air which has seemed pure. Concentrate that sunbeam by a lens, and the dust seems to become so thick that the vision cannot penetrate it; and one would be loath to take the next breath from that spot to which it would seem that all the dust in the room had betaken itself.

If such air comes in contact with hot surfaces, the organic matter in it is cooked and burnt; it is changed into a charred material, into fumes, into gases, and into smoke, and when ordinary dust-laden air touches surfaces which are overheated, the disagreeable results peculiar to overheating are largely due to the effect of heat on the floating matter which is in the air.



HEATING AND VENTILATING SCHOOL-HOUSES.

Concerning the statement that we need more air in warm weather than we do in cold weather, Professor Woodbridge said that organic matter is always present in the air. Two things are in general required to make that organic matter offensive, if not morbific. One is heat, and the other is moisture. The air is drier as it comes into our houses in the winter than it is in milder weather; in milder weather it is moist, and it is also warm; and because of those two conditions, favorable to the decomposition of organic matter in the air, much more air is required for comfort in warm weather than in cold weather, when it comes into our houses in a much drier condition. The drier the air and the colder the air, the less will be the quantity required for agreeableness and for health. The carbonic acid gas becomes then the principal thing which we have to consider as a test of impurity. But when the weather is mild and moist, other things force themselves on our consideration. An air quantity which would be perfectly satisfactory on a winter's day would not be tolerated in the summer season, when the air is moist as well as warm. It would not only be intolerable, it would be morbific. In the summer we must have open windows and a natural ventilation, compared with which in effective work artificial ventilation is child's play. We must have greater volumes as we increase the moisture of our air.

In answer to a question whether he had ever advised any special means for adding to the humidity of the air, Professor Woodbridge further stated that he had not done so as a rule except where it seemed to be required. The amount of evaporation necessary to effect any considerable change in the humidity of air can easily be figured out. It seems mere child's play to add the little amount by evaporation which we get by the ordinary methods employed for that purpose. If we figure it out we will find that it is very small. Let us do it roughly. We are passing into a school building with 50 pupils in it, 100,000 cubic feet of air an hour; we are taking it in from the outside at a temperature of 30, when its has, say, 1.5 grains of water to a cubic foot of air, we will raise the temperature to 70, say. It would hold about 8 grains of water at that temperature; therefore there would be just about 6.5 grains to be added to saturate or 4 grains to raise the relative humidity to 60. Multiply that by 100,000 and we have 400,000 grains of water to be added to the air in that school-room; that is so say, 400,000 divided by 7,000 equal 57 pounds of water per hour required to effect June humidity. Usually four or five pounds of water per hour is a generous rate of water evaporation in school-house furnaces or about one-third grain per cubic foot of air.

As much coal would be required for water evaporation as for heating the air. And then what have we got? A warm and moist air, and the organic matter in dust, vapor and other form becomes evident by its quicker decomposition, its offensiveness and its unwholesomeness, and, further, we have a humidity within doors which we do not get when we are outside, making the effect of a quick transition the more hazardous. Professor Woodbridge thinks that the conditions are excellent when we get pretty dry air, 20 per cent. or even 15 per cent of moisture. The English require a higher humidity because all their living is in a moister climate. Disease germs and zymotic diseases do not thrive in a perfectly dry state.

ACCORDING to the Peoria, Ill., *Transcript* a corps of Chicago engineers including H. A. Cranwell, A. Rosseau, E. J. Ward and F. W. Weidman, are making a survey of the Mississippi River. They are in the employ of the sanitary department of the city of Chicago, and are sent out preliminary to the construction of the drainage canal from the lakes to the Mississippi River.

THE Society of German Engineers, with its 31 branches, and numbering, in all, nearly 7,000 members, is probably the largest engineering association in the world.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

REGARDING DESIRABILITY OF CHANGES IN NORFOLK, VA., PLUMBING REGULATIONS.

W. T. **BROOKE**, City Engineer, of Norfolk, Va., writing on the Norfolk plumbing regulations in a recent letter, says:

"I beg leave to inclose you herewith a copy of our plumbing specifications, and also a copy of a letter from the master plumbers of this city, asking that the same be modified to suit their views. If not trespassing too far on your time, I would like some expression of opinion on your part as to the most prominent changes they desire.

"So far as the first change is concerned, I do not think there should be any change in the regulations where houses belong to different owners, or where there is a probability of their being sold to different parties, even if at present under one ownership.

"As to Section 3, its provisions are sometimes impracticable in very narrow alleys, and the Inspector of Plumbing has had to use discretion in such instances. The main points, however, on which I would like an expression of your opinion are:

"*First.*—Whether it would be good practice on long lateral drains from bath-tubs, basins, or other fixtures, not water-closets, to substitute 1¼-inch lead pipe for 2-inch iron (cast) pipe?

"*Second.*—Whether a wiped lead joint is not as technically correct as a wiped solder joint?

"*Third.*—If it would not be a faulty job to permit several fixtures to connect *straight* with one drain pipe, the latter to be trapped and vented after passing the last fixture?

"*Fourth.*—Whether fixtures on lower floors, emptying over yard traps should be trapped, and if trapped, should these be also vented?

"*Fifth.*—Whether P-traps entering a stack directly above any other fixture are permissible if not vented?

"*Sixth.*—Is it reasonable that bar-rooms should be exempted from regulations governing other houses?

"We have always read your journal with interest, and I, myself, am one of your subscribers. Therefore, having the utmost confidence in your judgment in all matters pertaining to sanitary usage, I would be glad if you can find time to consider the above questions. Of course, I have my firm opinions on the subjects presented, but think yours will be more potent."

The plumbing regulations referred to above are here reproduced for convenience of reference:

Specifications to Govern the Plumbing and Connecting Houses with the Public Sewers of the City of Norfolk Va. Adopted in 1883.

SECTION 1. Every house or building must be separately and individually connected with the nearest sewer.

SEC. 2. The drain and soil pipe must be laid as direct as possible, and to a uniform grade, with a fall of not less than 1 foot in 36, if possible, and all changes in direction must be made with curved pipes, and all connections with Y branches and one-eighth bends. The drain pipe must be laid at a sufficient depth to protect it from breakage or freezing.

SEC. 3. The house drains, when not entering into or underlying a building, may be of salt-glazed vitrified stoneware pipe, laid so as to have a uniform space between each spigot and socket end, the joints to be made with oakum gaskets well calked in, and finished with good strong fresh hydraulic cement mortar, composed of one part of cement and one of clean, sharp sand; the joint to be outwiped carefully and well pointed on the outside. But where drains enter and underlie a building the pipe must be of cast iron, to extend to and form part of the soil pipe, and extend at least 4 feet above the roof, or top of the highest window, of undiminished size, and terminate with a wire basket.

The iron drain pipe must extend at least 5 feet outside of every building, and all terra-cotta pipe inside of the building line of the street must be laid upon a foundation of hydraulic cement concrete, unless otherwise specially permitted by the city engineer.

SEC. 4. When a pipe passes through or under the walls of a building there shall be a relieving arch turned over it to protect it from breakage by the settling of the wall.

SEC. 5. The iron soil and drain pipe must be full 4 inches in interior diameter at every point, to be coated inside and outside with coal tar, applied hot. The horizontal portions of all iron pipes used under ground shall in no case weigh less than:

For 4-inch pipe, 13 pounds per lineal foot.
For 3-inch pipe, 9½ pounds per lineal foot.
For 2-inch pipe, 5½ pounds per lineal foot.

The joints are to be made with gaskets of picked oakum, and hot lead at one pouring, thoroughly calked in so as to render them impermeable to gases.

Waste pipes or lateral drains from bath tubs, basins, or other fixtures, with the exception of water-closets, may be of 2-inch diameter pipe.

SEC. 6. No trap or any manner of obstruction to the complete and perfectly free flow of air throughout the entire course of the drain or soil pipe will be permitted. No brick, sheet metal or earthenware flue shall be used as a sewer ventilator, nor shall any chimney flue be used for this purpose.

Pipes must be concentrated as much as possible, and where placed within walls they should be covered with wood work, fastened with screws, so as to give ready access to the pipes for inspection and repairs.

SEC. 7. All joints in waste-pipes, except where screw joints are used, must be made like those in the soil and drain pipes, with oakum gaskets and lead, well calked so as to render them gas-tight.

All connections of lead with iron pipes must be made with a brass sleeve or ferrule of the same size as the lead pipe; the sleeve to be put into the hub of the iron pipe and thoroughly calked with lead, and the lead pipe to be attached to the sleeve or ferrule by a wiped lead joint.

All connections of lead pipes must be by wiped lead joints.

SEC. 8. Every sink, basin, water-closet, wash tray, bath, safe urinal, and every tub or set of tubs, must be separately and effectively trapped; the traps to be of suitable and approved pattern, and to be placed as near the fixture as practicable.

All exit pipes, except in the case of water-closets, to be provided with strong metallic strainers.

SEC. 9. Every trap must be separately ventilated, and protected from syphonage by a special vent pipe not less than two inches in diameter for water-closets, nor less than 1¼ inches for other fixtures; but if exceeding 15 feet in length, this pipe shall not be less than 1½ inches in diameter.

These vent or air pipes should extend 4 feet above the roof, and terminate with a wire basket, but if they are branched into the soil-pipe, it must be above the inlet pipe of the highest fixture.

They may be continuous by branching together these which serve several traps, provided they are branched into a vent-pipe not less than 2 inches in interior diameter.

These vent or air pipes must always have a continuous slope to avoid collecting water by condensation.

SEC. 10. Every lead safe under a wash basin, bath, urinal, refrigerator or water-closet must be drained by a special pipe not directly connected with any waste-pipe, soil-pipe, drain or sewer, but must be discharged into an open sink or drain outside the house.

SEC. 11. Waste-pipes from wash-tubs, wash-stands and sinks shall not be connected with the trap of a water-closet.

SEC. 12. Water-closets must be of the hopper or approved pattern (pan closets being absolutely prohibited), and should be supplied from a special tank placed over them, in which case the waste or overflow from the tank must discharge into the open air, or the basin of the closet, and not into the soil-pipe directly.

Direct surface of a water-closet is always objectionable, and in case the water-closet is in a second or third story of a building, and above the supply to a kitchen or hydrant, it is absolutely prohibited.

SEC. 13. Wooden wash-trays and sinks are prohibited inside of buildings; they shall be of non-absorbent material.

SEC. 14. Lead, zinc or galvanized iron linings for house cisterns are prohibited, but wood, iron or tinned copper may be used. In every instance the overflow must be trapped into the open air.

SEC. 15. All materials must be of good quality, and free from al defects; the work must be executed in a thorough and workmanlike manner, and subject to the approval of the City Engineer and the Inspector of Plumbing.

SEC. 16. The foregoing regulations and specifications will be altered, amended and added to, whenever it may be deemed by the Board of Street, Sewer and Drain Commissioners proper to do so.

SEC. 17. Prosecution for infringement upon the provisions of these regulations and specifications shall be made by information filed in the Mayor's Court, in the city of Norfolk, Va.

The Norfolk Master Plumbers' letter, asking for modifications, reads as follows.

To the Honorable Board of Street, Sewer and Drain Commissioners:

GENTLEMEN: At a meeting of the master plumbers of this city, held on Saturday evening, August 23, and after carefully considering the specifications governing house plumbing and drainage by sections, we would most respectfully submit the following changes and additions to your notice, and ask the same to be adopted by your Board:

SECTION 1. Insert the word *practical* to make Section 1 read as follows: "Every house or building must, *when practical*, be separately and individually connected, etc."

SECTION 3. Strike out the last paragraph.

SECTION 4. Strike out entirely.

SECTION 5. Add to last paragraph, "and not less than 1¼ inch lead pipe."

SECTION 7. Insert "solder" in place of "lead," next to last word in last two paragraphs.

SECTION 8. After "basin," in first line, insert "and set of basins;" and after "tray," in second line, insert "and set of trays."

SECTION 9 Add "providing that this section shall not apply to fixtures on first floor, and emptying into or over yard traps."

SECTION 17. Make a new section, "P traps entering a stack direct and not more than two feet from same, where there is no fixture above, may not be back vented."

SECTION 18. Make a new section: "The use of traps without ventilating pipes will be permitted to connect direct in bar-rooms, if provided with McClellan Anti-Syphon Vent."

Respectfully submitted,
THE MASTER PLUMBERS OF THE CITY OF NORFOLK,
T. J. CARRY, Secretary.

[SECTION 1. Recommendation not concurred in. Experience has shown the importance of this regulation. Our correspondent cites some of the reasons in its favor.

SECTION 3. If discretion be vested in any one over details to be adopted in special cases, and the City Engineer is the party to exercise that discretion, we see no reason for striking out the clause referred to, except to relieve him from importunities and the embarrassment of refusing requests from acquaintances.

SECTION 4. Recommendation not concurred in, unless provision is made to require that the wall should not rest on the pipe. It is not always practicable to locate, in foundation walls, the opening for the drain. When the hole is cut for it, a good plan is to surround the cast-iron pipe with a wrought-iron pipe of larger diameter, and pack the intervening space with some compressible substance, like mineral wool, so that a small settlement could not break the drain pipe.

SECTION 5. Since the original clause is not mandatory, but simply suggests what may be used, the recommendation for Section 5 seems all right, since it is assumed that there are situations when a lateral pipe, being only a few feet long, may safely be lead pipe for the few feet between the fixture it serves and the vertical soil pipe. This amendment is apparently intended to prevent the using of pipe smaller than 1¼-inch, which is proper. The size of a waste-pipe should, within certain limits of course, be determined by the duty it has to perform in the particular case, and we presume that when a plan of work is submitted to the local authority the various sizes are specified on the plan, and before work is done to be approved by said authority.

SECTION 7. This recommendation is indorsed.

SECTION 8. Recommendation as to wash trays concurred in, but not as to wash basins. The latter should be, in every case, separately trapped.

SECTION 9. This recommendation could be construed to exempt all traps on the first floors of buildings. It is, therefore, not concurred in. There may be special cases where, in a detached building, the only fixture in it may be trapped close to a vertical soil-pipe or discharge, as indicated, over a yard trap, when venting the trap may not be necessary. Discretion should be vested in some one to permit a special construction in such cases adequate for the purpose. Such exemption to be a matter of special permit, on file in the department as a record of the transaction.

SECTION 17. Exemption of this character should be subject to special permission in each particular ease, and it should not be restricted to P traps, since there are other forms that, in the absence of vents, may be more desirable.

SECTION 18. We do not see the reason for exempting bar-rooms from the regulations governing other houses.

In conclusion, we would say that our comments are based on our impression of conditions that may be supposed to exist in a city like Norfolk, where there doubtless are detached houses with plumbing only on a single floor, and that possibly restricted to a single sink. In such cases a system of work might be permitted that could not be safely allowed in other places. The idea of the master plumbers of a city meeting from time to time, and making suggestions based on their experience with regard to existing plumbing regulations, is a most commendable one, and it should be encouraged since the co-operation of the local plumbing associations has been of great assistance in securing and enforcing of plumbing regulations in different cities. It often happens, however, that a recommendation is suggested by a single experience, and the embarrassing effect in the matter of enforcement of having a regulation for every contingency likely to arise is not fully appreciated.

Committees of plumbers, in suggesting changes in plumbing regulations, sometimes fail to realize that though a change for special places might be permissible, yet the greatest good of the greatest number would be best secured by not weakening a good regulation by incorporating a lot of possible exemptions. A conference between those who have to hear and refuse all sorts of requests and be responsible for enforcement, and committees selected to suggest changes always will have a good effect. The problems can then be seen from different points of view.

We shall be glad to have the subject further discussed by our readers.]

PLUMBING IN A KANSAS CITY RESIDENCE

"Two or Three Plumbers," of Kansas City, Mo., write: "In your issue of August 23 the plan of plumbing in a Kansas City residence has caused a great discussion in the shop where we are employed. It is a new scheme to all of us. We fail to see where or how Mr. Grey can have a circulation of air through the system, even with the steam coil. What is to promote circulation in summer, when there is no steam used in the building? With steam on, we think the basement closet will have all the benefit, as that back air pipe is the only direct connection we can trace out from the fresh air inlet, except the soil pipe through roof. And, as air, like water, will take the easiest course, the rest of the system will not be benefited by this way of back airing. Perhaps Mr. Grey or T. H. S. can explain how it is to be done."

Novelties.

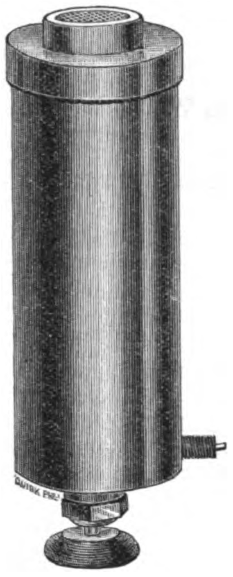
Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply indorsement.

THE DIMMICK AIR MOISTENER.

THE Philadelphia Exhaust Ventilator Company, 520 Commerce Street, Philadelphia, Pa., are about to put on the market what will be known as the Dimmick Air Moistener, of which an illustration is annexed. It may be made to take the place of an air valve on a radiator, being screwed into the latter, and is operated by a valve. Steam, entering the moistener, is partially condensed and can be brought in contact, within the apparatus, with any desired aromatic substance, and, escaping through the perforated removable cap at the top, imparts the odor to the atmosphere.



The device is said to be useful in preventing cracking and splitting of furniture in steam-heated rooms, and to overcome any objectionable dryness of the atmosphere. It is also claimed to be serviceable in diffusing disinfectants.

DEATH IN A CESSPOOL.

ON Thursday morning, September 4, three men lost their lives in attempting to clean a cesspool at West Brighton, S. I. The cesspool was about 12 feet deep. The first man fell before reaching the bottom, overcome by the gas. The other two were similarly affected in going to his assistance. As far as can be learned no means were adopted to ventilate or purify the air of the cesspool before entering the latter.

ACCORDING to Pittsburg reports, two of the largest gas wells ever developed in that district have been found. One of the wells is located near Bellevernon, and is owned by the Philadelphia Company. The other is the property of the Bridgewater Gas Company, and is in the Wildwood Field. It is estimated that both are good for 800 pounds pressure. The gas from these wells, it is said, would be sufficient to run half the mills in the city, and would seem to dispose of the stories that the gas was giving out.

A FRENCH engineer, M. Decoeur, is said to have under way a project of supplying Paris with electric power to be generated by the change of the tides on the coast.

CONNECTING STEAM PIPES TO BOILERS.

THE August number of *The Locomotive*, published by the Hartford, Conn., Steam Boiler Inspection and Insurance Company, is given up wholly to a series of articles on steam pipe connections to boilers and rotaries, and the support of long lines of pipe. While the matter is not new, experience has shown that it is not so familiar to those usually connected with the work as it ought to be, and it will, therefore, well bear repetition. In the annexed illustrations we have, accordingly, reproduced several diagrams relating to steam pipe connections to boilers.

Concerning these, *The Locomotive* very appropriately says that the points to be considered, but which are very often neglected, are to provide for the effects of expansion, and also to make allowance for any settling of the boilers which may, and generally does, occur after they have been run a short time.

Figure 1 shows a case where two boilers were improperly connected. Cast-iron tees were bolted to the nozzles, and connected by means of a cast-iron pipe, which had an outlet on top, as shown, from which the steam pipe was led. It will be seen at once that the boilers were rigidly bound together by this arrangement. After a short time the tee on No. 2 cracked off as shown at A; this was replaced with a new one, and soon afterward the pipe connecting the two boilers broke off at B. Both these breaks occurred while the boilers were in use, and of course resulted in their stoppage until the broken pieces could be renewed. The only strange thing in connection with the affair was the fact that the breaks did not occur the first time steam was gotten up.

Cast-iron pipe should be used with caution for such purposes, as, from its brittle nature, accidents are liable to occur at any time. Wrought-iron pipe is better every way, and should always be used. But in no case can the use of such connections as that shown in Fig. 1 be justified. Only a very inexperienced engineer would design such a connection, and no steam fitter should put it up without entering a strong protest against it. No provision whatever is made for the motion of the boilers due to expansion, or settling of the foundations or walls.

Figures 2 and 3 show a properly-designed arrangement of steam connections for a battery of boilers. Wrought-iron pipe is used. To the nozzles risers are attached by means of flanges, and from the upper ends of these risers pipes are led horizontally backwards into the main steam pipe. In this horizontal pipe, the stop-valves, one to each boiler, are placed. These valves should have flanged ends, as shown, so that they may be easily removed, if repairs become necessary, without disturbing any other portion of the piping. The main steam pipe may be supported by means of long hangers, from the roof of the boiler house, when practicable, or if this cannot be done, it may be held up by posts which rest on the back wall of the boiler setting, or any other convenient place.

By this arrangement it will be seen that the movements of the boilers and the piping itself are compensated for by the spring of the pipes, and no trouble will ever occur. The height of the risers should never be less than 3 feet, and when there are eight or ten boilers in one battery, they should be, if room permits, 6 to 8 feet high, and the horizontal pipes leading to main steam pipe should be 10 to 12 feet or more.

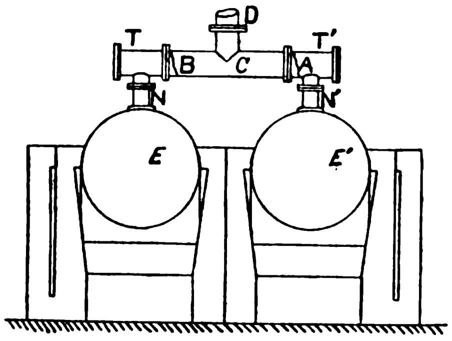


FIG. 1.

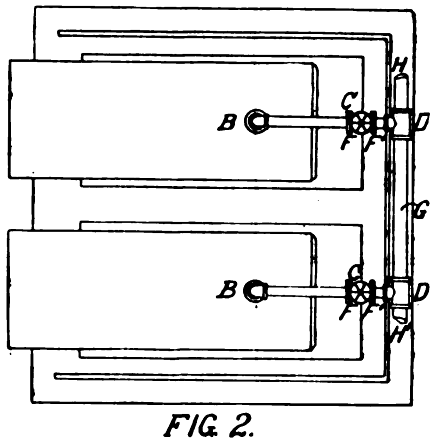

FIG. 2.

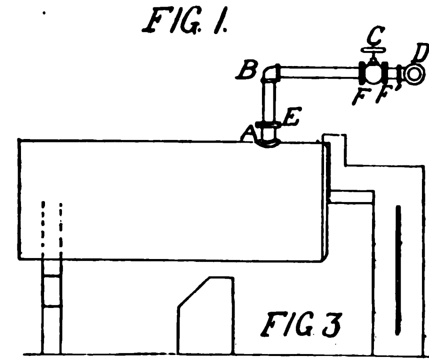

FIG 3

CONNECTING STEAM PIPES TO BOILERS

USES OF ASBESTOS.

WITHIN recent years the practical applications of asbestos have largely multiplied in number, and the material is now being extensively employed for protection purposes in workshops, foundries and mills, to guard against the danger of burning the hands and face, and generally to make working in hot metals a safer and more comfortable occupation. Asbestos mittens to guard the hands are made for firemen, assayers, refiners, etc., and armed with a pair, the artisan or worker can grasp hot irons, crucibles and the like without discomfort. Masks, too, for the face are made of asbestos, which are fire proof, and the heat from the hottest fire is said not to penetrate to the skin. Air is drawn from beneath the mask for breathing, so that the burned or flame and smoke-laden atmosphere is not inhaled. Aprons and insulating coverings for the entire body are also constructed, having like protective qualities, and for firemen complete suits of asbestos fire-proof cloth are made. For domestic use sad-iron holders of asbestos may be had, and with these the grasp of the iron, however hot it may be, never causes pain or burning. Plumbers are likely to welcome asbestos cloths for joint wiping, and large holders, intended for use by smelters, molders and workers in metal generally are among the more recent uses of this mineral. The asbestos thus prepared is very flexible, and even the mittens are said to be sufficiently pliable to permit of small objects being readily picked up and held in the hand wearing them.

BRICK PAVEMENTS IN HOLLAND.

THE brick pavements at the Hague are made of a hard-burned brick, 22 centimeters (8.668 inches) long, 11 (4.33 inches) wide, and 5½ (2.16 inches) thick. They are laid on a sand foundation 20 centimeters (7.88 inches) deep, with very little clay, as otherwise proper drainage is interfered with; joints are laid as close as possible. The Hague being a city of residences, the street traffic is light.

TRADE PUBLICATIONS.

MAHONY STEAM AND HOT-WATER BOILERS.

M. Mahony, Troy, N. Y,, has just issued a new, neatly prepared and attractive catalogue, devoted to his boilers for steam and hot-water heating. The customary price-lists and tables of sizes are given, accompanied by illustrations of the several forms of Mahony boilers, and a large number of views of buildings warmed by them.

Short chapters on estimating the size of heating apparatus required, and on the proportion of radiating surface to space to be heated, together with testimonials, occupy the concluding pages.

A LARGE PIPE CASTING.

THE Newport, Ky., branch of the Addyston Pipe and Steel Company, of Cincinnati, O., recently turned out the largest pipe casting ever attempted in this country, the pipe being 60 inches in diameter. This is about double the size of any heretofore made.

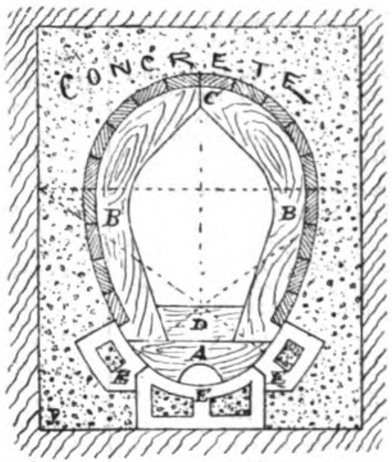
Each section of pipe will be 12 feet 4 inches in length, and will weigh 10,800 pounds; in thickness the pipe will be 1⅜ inch. The patterns, flasks and tools necessary to turn out this monster were made at the foundry, and the casting ladle will hold nine tons of molten iron. The pipe goes to Milwaukee, 800 lengths being contracted for, to be used for bringing water from the lake.

A CONCRETE SEWER.

A RECENT issue of London *Iron* describes a sewer half a mile long, built in 1867 at Sidmouth, Devonshire, by John Standfield, M. Inst., C. E.

It was at first intended to build the sewer of hard brick laid in Portland cement, but the high cost of brick at that place caused a concrete made of fine, medium, and coarse shingle (six parts) and Portland cement (one part) to be used, except the three invert courses of stoneware blocks E E E which were filled with concrete before they were laid.

The centering was formed thus: A was a foot-block of wood and B B wood ribs standing thereon and abutting at the top C against each other. D was a wedge block of wood, keeping the ribs tight against the invert blocks. The wood laggings around the ribs were 12 feet long. These butt-jointed midway on two end ribs, and rested on two intermediate ribs, and thick boards were laid on the blocks D for the bricklayers to stand on to build up the sides, haunches and crown of the sewer with concrete.



A CONCRETE SEWER.

SIZES OF LIGHTNING RODS.

SPEAKING of lightning rods, the *Verkehrs Zeitung* points out the desirability of making them of sufficient diameter to preclude the possibility of excessive heating. Arago has determined that an iron rod or wire of a diameter of 0.5416 inch will meet this requirement even with the heaviest electrical discharges. In view of the fact, however, that copper, zinc, and even lead wire is sometimes used in the manufacture of lightning rods, the appended table is presented, giving the diameter which should be used for wires of different metals and alloys. It was prepared by Dr. Rothen of the Swiss Telegraph Bureau:

	Diameter in inches.
Copper	0.384
Platinum	0.512
Iron	0.494
Zinc	0.592
Brass	0.624
Lead	0.848

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

For works for which proposals are requested see also the "Proposal Columns,' pages i-ii-239.

WATER.

For Additional Water Items see Proposal Columns.

HENRIETTA, TEXAS.—It is probable that a water-works plant will be established at this place by the Henrietta Improvement and Water Company.

LAKE FOREST, ILL.—The citizens of this place have organized a company for the purpose of establishing at once a complete system of water-works.

CASTLE ROCK, COL.—A complete system of water-works is to be established at this place by the Castle Rock Water Company.

BURLINGTON, COL.—It is probable that immediate steps will be taken to remedy the trouble resulting at this place on account of the scarcity of water. An entire new water-works system is talked of.

OENAVILLE, TEXAS.—Reports say that this place is to establish a system of water-works.

CHAMBERSBURG, GA.—The borough has decided to erect both steam and water pumping machinery and build an additional reservoir of 2,000,000 gallons capacity.

WENHAM, MASS.—This place is to be provided with a water supply.

HAMILTON, MASS.—A water-works system is soon to be established at this place.

SANTA ANA, CAL.—At a recent election held at this place the sum of $6,000 was appropriated with which to establish a system of water-works.

GREELEY CENTER, NEB.—The people of this place have voted in favor of water-works.

ALGONA, IA.—The contract for the construction of a system of water-works at this place has been awarded to Messrs. Harrison & Hawley, of St. Paul, Minn.

DECORAH, IA.—The contract for furnishing, etc , water mains at this city has been awarded to Messrs. Harrison & Hawley, of St. Paul, Minn.

HENDERSON, MINN.—It is proposed to establish a system of water-works at this place. The Town Clerk can furnish particulars,

SAVANNAH, GA.—Water-Works Superintendent Manning is reported as saying that the city needs a new high duty engine.

KALKASKA, MICH.—The question of appropriating the sum of $25,000 for the purpose of establishing a system of water-works is to be decided at a public election to be held at an early day.

CHAMBERSBURG, PA.—Plans just adopted for the proposed additional water supply for this place estimate the cost of the work at $26,000. The engineer in charge is John Birkinbine, C. E., as above.

DOVER, N. J.—Improvements and extensions will soon be made to the water-works plant at this place.

JELLICO, TENN.—The Mayor can furnish particulars of a project to establish a system of water-works at this place.

MANCHESTER, N. H.—Reports say that it has been recommended to construct a reservoir, with a capacity of 3,000,000 gallons, on Oak Hill.

ST. LOUIS, MO.—The Sunset Hill Electric Light, Water and Power Company has been incorporated here. Capital stock, $100,000. Incorporators, Marcus Bernheimer, Herman Tubolske, and others.

WINCHESTER, TENN.—Reports say that this place is to have a system of water-works.

GATESVILLE, TEX.—A system of water-works is to be established at this place by the Gatesville Water Supply Company.

MACON, GA.—At a recent meeting a resolution was passed instructing the Mayor to advertise for bids for building new water-works.

WYOMING, O.—Our correspondent writes: "Mayor R. D. Barney is the chairman of a committee to raise $30,000 for the construction of a system of water-works at this place. It is expected that the full amount will be subscribed."

HELENA, MONT.—The Eureka Reservoir Canal and Irrigation Company has been formed at this place. Capital stock, $200,000. Z. T. Burton is president.

HELENA, ARK.—According to reports St. Louis parties will establish a system of water-works at this place. Surveys, it is said, have already been made.

MORRISTOWN, TENN.—This place is to have a system of water-works.

OXFORD, N. C.—The people will settle the question of bonding this place in the sum of $50,000 for water-works, at a public election.

MOUNT STERLING, KY.—The people of this place voted recently in favor of establishing a water-works system.

SPRINGFIELD, S. D.—It is probable that the water-works proposed for this place will be constructed at once.

COLUMBIA, S. C.—The Water-Works Committee recommends the purchase of water-wheels and pumps to the amount of $25,000, to increase the supply of water.

TARRYTOWN, N. Y.—To increase the village water supply, a contract has been awarded to J. A. Lockwood to sink two new wells, at a cost of $11,000.

LANCASTER, PA.—It is probable that improvements will be made to the local water-works system.

TROY, N. Y.—At a special meeting of the water-board held September, several additional water-mains were recommended. Commissioner Gleason can furnish particulars.

KNOXVILLE, TENN.—It is probable that the proposed improvements to the local water-works system will consist of adding two pumps and building an additional reservoir.

CLEVELAND, O.—Numerous water-main extensions are to be made in this city.

SOUTH ORANGE, N. J.—H. H. Hart, chairman Water Committee, writes: "This village will issue $20,000 of four per cent. water bonds at par, to run for 20 years, with option of village to redeem after five years. This is the only bonded debt of the village, the assessed valuation of the real estate of which is nearly $2,000,000; the annual taxes raised are about $18,000. See Proposal Columns for particulars of projected work on which bids are invited.

BROOKVILLE, IND.—City Clerk J. W. Cates writes: "We have had an engineer to draw up the requisite plans, specifications, costs, etc , for water-works, and we intend to set an election, in this September 8 meeting of Board. We want direct pressure, as we think it the cheaper, and we are limited to $19,500."

ALTOONA, PA.—City Clerk H. T. Heinsling writes: "City Council, by resolution, has directed the City Solicitor to prepare an ordinance, submitting to the citizens of Altoona by vote, whether an additional stream be secured to increase the water supply of the city or whether an impounding reservoir be built, below the present reservoir, at an estimated cost of $200,000, with a capacity of 370,000,000 gallons."

NEWMANSTOWN, PA.—Town Clerk W. W. Stewart writes: "A charter is granted and the survey taken for the introduction of water to Newmanstown and Sheridan, Lebanon County, Pa., from the South Mountain springs. I do not know when the company begins at it."

MERIDEN, CONN.—Numerous water-main extensions are to be made at this place. Mayor Page can furnish information.

BROOKFIELD, MO.—City Clerk D. F. Howard writes: "Nothing has been done in regard to water-works. They vote on bonding the town for that purpose the 23d of this month."

WELLESLEY, MASS.—Town Clerk Fred H. Kingsbury writes: "I know of no improvements to be made this year except the putting in of some two miles of pipe on streets not before piped."

TRENTON, TENN.—Water Commissioner W. B. Stafford writes: "Our city voted $20,000 to put in a water-works system."

MIDDLEBURY, VT.—A. A. Fletcher, the Chairman of the Water Committee, writes: "We have had a survey made and cost estimated. We have had a village meeting, when it was voted to bond the village for water-works for fire and domestic purposes. Expected to have had the work commenced before this time."

JEFFERSONVILLE, IND.—The pumping machinery of the local water-works plant is to be remodeled, after plans made by John W. Hill, C. E., of Cincinnati, O.

EATON, O.—Plans are under way for a system of water-works to be established at this place. Address John W. Hill, C. E., the engineer, at Cincinnati, O., for particulars.

MADISON, IND.—Improvements are to be made to the water-works system at this place. John W. Hill, C. E., of Cincinnati, O., has charge of the work.

MANCHESTER, N. H.—M. M. Tidd, C. E., Boston, has been making an examination with the view of making plans for the construction of a system of high service water-works for this place.

SAN JOSE, CAL.—The Glen Weber Water Company has been formed in this city, to supply San Jose, San Francisco and Oakland with water. For particulars, address John W. Combs, as above.

BUENA VISTA, GA.—The people of this place want water-works.

PATCHOGUE, L. I.—Reports say that the Gerard Farm, near here, is to be turned into a settlement and that it is to be furnished with a private water-works system. Supervisor F. W. Dunton, of Jamaica, L. I., can furnish particulars.

FREEHOLD, N. J.—The contracts for the construction of the water-works, at this place, were awarded September 8. The contract for pipe was given to the Union Hydraulic Company, of Philadelphia, whose bid was $16,452.37; for laying the mains, refilling the trenches, etc., complete, to H. B. Pitcher, Long Branch, who bid $7,592.16; the special castings to the Union Hydraulic Company, at 2½ cents per pound; and the fire hydrants to the Eddy Valve Company, for $23.90 each. Proposals for the stand-pipe, to hold 240,000 gallons, the pump, engine and boilers, will be opened on the 20th inst. There will be over eight miles of mains. The supply will be obtained from artesian wells.

FRANKLIN, IND.—The Secretary of the Franklin Light and Power Company writes: "Will be ready for bids on pumping machinery and boiler in a short while."

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Coldwater, Mich.; Rushville, Ind.; Yoakum, Tex.; Toledo, Iowa; Dallas, Tex.; Allegheny, Pa.; Atlanta, Ga.; Austin, Tex.; South Orange, N. J.

READERS of **THE ENGINEERING AND BUILDING RECORD** interested in the Contracting News Department of that paper are respectfully requested to examine those columns every week, and advise the Editor of any item which they may find that, in their judgment, is of no value to any one other than the person mentioned.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

WILMINGTON, DEL.—The contract for the construction of certain sewers at this place has been awarded to John Jacoby, of Wilmington, Del., at $43,337.29. The figures in detail were as follows: Brick sewer, 3 feet 3 inches, circular, $6 per foot; brick sewer, 2 feet 6 inches by 3 feet 9 inches, $6; brick sewer, 2 feet 4 inches by 3 feet 6 inches, $5.35; brick sewer, 2 feet 2 inches by 3 feet 3 inches, $4.50; brick sewer, 2 feet by 3 feet, $3.20; brick sewer, 2 feet, circular, 1 ring, $2.64; brick sewer, 2 feet 7 inches by 3 feet 10½ inches, $6; brick sewer, 2 feet 5 inches by 3 feet 7½ inches, $5.73; brick sewer, 2 feet 3 inches by 3 feet 4½ inches, $5.50; 20-inch terra cotta pipe, $1.75; 18-inch terra cotta, $1.60; 15-inch terra cotta, $1.30; 12-inch terra cotta, 90 cents; 10-inch terra cotta, $1; 8-inch terra cotta, 80 cents; inlets and catch basins, $77; manholes in brick sewer, $65; manholes in pipe sewer, $65; vitrified fire brick per 1,000, $20; rock excavation, per cubic yard, $2.

Kennedy, De Law & Co., of Philadelphia, Pa., were the only other bidders, and their total figure was $49,830.21.

BUFFALO, N. Y.—The projected sewer through Ferry Street, in this city, is to be constructed.

WILLIAMSPORT, PA.—Plans have been adopted for a system of sewers for this city.

JERSEY CITY, N. J.—Reports say that it is proposed to expend the sum of $200,000 on the construction of additional sewers in this city.

SCRANTON, PA.—An effort is being made to make sewer improvements at this place at a proposed expenditure of $75,000.

SANTA ANA, CAL.—The question of establishing a system of sewers at this place is now under discussion.

COLUMBUS, GA.—This city will commence at once the construction of the sewerage system. D. P. Dozier, Mayor, can give particulars.

VICKSBURG, MISS.—Plans and specifications for the Vicksburg new sewerage system were accepted by the City Council September 2. They call for 20 miles of mains and laterals at an estimated cost of $192,000. The city was only authorized to expend $100,000, so the matter of building is still under consideration.

HARRIMAN, TENN.—M. M. Tidd, C. E., Boston, has prepared plans for a system of sewerage for this place, and submitted them to the East Tennessee Land Company.

PAWTUCKET, R. I.—A. R. Sweet writes from this place as follows: "This city has, for the Blackstone River water-shed, established a restricted combined system of sewerage, with a view for future disposal by land treatment. At present the sewage is emptied into the Seekonk River, a tidal stream. There has been built for this district 13 out of the 29 miles required. For the Moshassuck River water-shed the same system is proposed and at present under way. About one and one-half miles have been ordered built. The sewage from this district will be treated either by chemical precipitation with filtration or irrigation; probably irrigation."

NEW HAVEN, CONN.—The following bids for the construction of certain sewers on pile foundations in this city were received by A. B. Hill, City Engineer, September 4: M. A. Blakeman, Bridgeport, Conn., per lineal foot, $7.80; C. R. Waterhouse, New Haven, Conn., per lineal foot, $6.39; C. W. Blakeslee & Sons, New Haven, Conn., per lineal foot, $6.29; Robert Lutz, New Haven, Conn., per lineal foot, $6.25.

READING, PA.—An ordinance has been introduced in the Select Council, providing for a $300,000 loan for the construction of underground sewers, the voters to express their assent or dissent at the polls on November 4.

KEY WEST, FLA.—The local sewerage system is to undergo extensive improvements.

HAMILTON, ONT.—About $10,000 is to be expended on improving the sewerage system of this place.

ST. LOUIS, MO.—The following proposals for the construction of about 76,000 feet of sewers, were opened by R. E. McMath, C. E., Sewer Commissioner. The figures given are for the following work in detail: Earth excavation, 98,100 cubic yards; rock excavation, 800 cubic yards; rubble masonry, 10 cubic yards; brick masonry, 14,200 cubic yards; 12-inch pipe sewer, 18,800 feet; 15-inch pipe sewer, 15,450 feet; 18-inch pipe sewer, 10.635 feet; 21-inch pipe sewer, 825 feet; 24-inch pipe sewer, 5,235 feet; inlet stone, 6,804 square feet; cast iron, 188,500 pounds; wrought iron, 22,120 pounds; junctions, 3,825 pieces.

Bidders—A. Heman and J. Fruin, St. Louis, Mo., 40 cents, $3, $4. $8, $1.5, $1.25, $1.70, $2, $2.25, 70 cents, 3 cents, 5 cents; total, $241,254.55. Fruin Bambrick Construction Co., St. Louis, Mo., 45 cents, $350, $5. $8.50, $1,15, $1.35, $1.80, $2.25, $2.75, 80 cents, 3 cents, 6 cents; total, $262,258.90.

WHEELING, W. VA.—Thomas F. Thoner, City Clerk, writes: "We have expended very near $20,000 in sewerage so far this year and expect to spend from $5,000 to $10,000 more during this month."

SEWERS.—See our Proposal Columns for information regarding sewer work at the following places: Para, Brazil; Key West, Fla.; Iron Mountain, Mich.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns

KNOXVILLE, TENN.—Rumors say that the Cherokee Land Company proposes to construct an iron bridge across the Tennessee River, near this city, at a cost of $100,000.

HUNTERDON COUNTY, N. J.—The Commissioners of this county have decided to make an expenditure of $8,000 in repairing numerous county bridges.

ST. PAUL, MINN.—The city clerk has been authorized to advertise for bids for the bridge across the right of way of the Wisconsin Central Road at Mississippi Street.

ST. PAUL, MINN.—The report of the Council Committee on Ways and Means in favor of allowing $50,000 upon the Selby Avenue Cable Line Bridge has been approved. The report of the same committee in favor of building a bridge across the Wisconsin Central tracks at Mississippi Street, at a cost of not more than $2,400, has been referred to the city attorney.

DULUTH, MINN.—A $2,000 bridge will be built over the railroad tracks.

WASHINGTON, D. C.—The House has passed a bill authorizing the construction of a bridge across the Savannah River, by the Middle Georgia and Atlantic Railroad Co.

AMESBURY, MASS.—The County Commissioners have decided on the plans for a new draw-bridge and approaches for the Powow River. The work will be done under the general supervision of C. A. Putnam, C. E., of Salem, Mass.

PORT ROYAL, TENN.—The estimated cost of the proposed bridge to span the Red River, at this place, is $8,500.

EAST TEXAS, PA.—The County Commissioners will soon ask for bids for the erection of an iron bridge over the Little Lehigh River, at this place.

HAMPTON COUNTY, VA.—The Board of Supervisors of Hampton County has appropriated $16,000 to build an iron bridge across the Hampton River. The bridge will be used by the Old Point and Hampton Street Railroad.

HORNELLSVILLE, N Y.—Kinzua Bridge is to be removed and replaced by a structure much more substantial. The Chief Engineer of the Erie Railroad can furnish information.

SCRANTON, PA.—It is proposed to bond this city for the purpose of erecting four iron bridges.

BRIDGES.—See our Proposal Columns for information regarding bridge construction at the following places: New Gretna, N. J.; Atchison, Kan.; Reading, Pa.; San Antonio, Tex.

NEW DEPOTS.

GRAND FORKS, DAK.—A passenger depot will be built by the Great Northern, formerly the St. Paul, Minneapolis & Manitoba Road, to cost $20,000. Kettle River sandstone will be used.

AMBLER, PA.—The Reading Railroad Company's officials have been negotiating for a piece of ground on which to erect a large freight station.

STREET-WORK AND PAVING.

MOUNT VERNON, N. Y.—The Board of Trustees has decided to go ahead with macadamizing the village streets, with $100,000 recently voted for the purpose at a public meeting of taxpayers.

DANVILLE, ILL.—T. W. Marshall & Co., general contractors, of Chicago and Peoria, have been awarded the contract for paving, with small brick, 40,000 yards.

SALT LAKE CITY, UTAH.—Considerable street paving is to be done in this city.

SIOUX CITY, IOWA.—Considerable road work is to be done in the vicinity of this city.

ASBURY PARK, N. J.—The Long Branch Commissioners have decided to have Ocean Avenue, from North Long Branch to Brighton Avenue, near the West End Hotel, surveyed so as to get a uniform width of roadway and then advertise for bids for the repairing of the same.

KEY WEST, FLA.—Extensive paving operations are to be commenced in this city at an early day. The estimated expenditure of the work is $200,000.

SAVANNAH, GA.—Estimates are being made for the paving of numerous streets with asphalt.

GAS AND ELECTRIC LIGHTING.

DOYLESTOWN, PA.—This place has decided to do away with gas illumination in favor of the electric light.

SEATTLE, WASH.—The Seattle Gas and Electric Light Company has been incorporated. Capital stock, $600,000. Incorporators, Dexter Horton, A A Denny, and others. The objects of the corporation are to establish and maintain gas and electric light plants in this city.

GRAND RAPIDS, MICH.—All bids for public lighting have been rejected by the Council, and the City Clerk has been directed to readvertise for proposals.

JAMAICA, N. Y.—At a recent meeting of the Board of Trustees of this place, all the bids for public lighting were rejected, and the Clerk of the Board was directed to readvertise for bids for lighting the streets all night and every night for a period of three years; that the candle-power bid for electric light must not be less than 32 candle power, and not less than 20 candle power for 4-foot gas burners.

PITTSBURG, PA.—The Pittsburg *Dispatch*, of September 6, says: "There is talk of an electric light company being formed in the West End for the purpose of supplying private residences and business houses. A meeting of those interested in the enterprise has already been held, and all that remains to complete arrangements for organization is the subscription for stock. It is not known yet what the capital stock is to be, but it is said the plant will be large enough to supply all of the West End and the thickly settled portions of Chartiers township.

CLIFTON, PA.—An electric lighting plant is to be established at this place.

WETUMPKA, ALA.—Reports say that an electric light plant is to be established at this place.

WINCHESTER, TENN.—An electric lighting plant is to be established at this place.

SANTA FE, N. M.—It is proposed to establish an electric light plant at this place at an estimated cost of $25,000. C. F. A. Fischer, of this city, can furnish particulars.

MOUNT STERLING.—The Mt. Sterling Electric Light Company has made the city a proposition to erect an electric light plant.

PHILADELPHIA, PA.—The Suburban Electric Co., has been incorporated at this place with a capital of $200,000. The directors are T. W. South, H. A. Mullin and others.

QUINCY, MASS.—Improvements are to be made to the local electric light plant.

ELGIN, ILL.—Improvements are soon to be made to the plant of the American Gas Light Company.

BUENA VISTA, GA.—Efforts are being made to establish an electric light plant here.

HOWELL, MICH.—It is probable that the projected electric light plant for this place will be established at once by the Howell Electric Light and Power Company.

BIRMINGHAM, ALA.—The Consolidated Electric Light Company has been incorporated here. Address J. F. B. Jackson for details.

SAN FRANCISCO, CAL.—Reports say that extensive works will be erected on the property of the San Francisco Gas Lighting Company.

PORT JERVIS, N. Y.—The Deer Park Electric Light Company has been awarded the contract for lighting this city for a period of two years from June 1, 1890, at a cost of $105 each for the first 83 lights, and $90 for each additional light.

MIDDLETOWN, DEL.—The electric lighting plant at this place is to undergo extensive improvements. Among the improvements is included a new engine, also new boilers and dynamos. Address J. B. Brattan for particulars.

DAYTON, KY.—The Citizens' Electric Co. is a new concern at this place. The capital stock is $25,000, and the secretary is Charles Bird.

SANDWICH, ILL.—This place will soon establish an electric light plant.

FRACKVILLE, PA.—The Frackville and Gilberton Light, Heat and Power Company, has been incorporated here. Capital stock, $40,000.

BAY CITY, MICH.—An electric lighting plant is to be established at this place.

SANGER, CAL.—This place is to have electric lights.

TACOMA, WASH.—The Commercial Electric Light and Power Company has been incorporated at this place with a capital stock of $250,000.

HAWKINSVILLE, GA.—The people of this place are discussing the electric light question. Captain O. A. Horne can be addressed.

SELMA, ALA.—Reports say that the Selma Electric Light and Gas Company will, at an early date, put in an incandescent plant.

DOVER, PA.—Improvements are to be made to the local electric light plant.

MONROE, N. C.—The electric light question is to be settled at a public election, to be held at an early date.

ELECTRIC RAILWAYS.—New electric railways are to be constructed and improvements are to be made to those already established at the following places: Maysville, Ky.; Hollidaysburg, Pa.; Allentown, Pa.; Wakefield, Mass.; Chicago, Ill.; Newport, Ky.; Hartford, Conn.; Wethersfield, Conn.; Houston, Tex.; Lykens, Pa.; Trenton, N. J.; Seattle, Wash; Passaic, N. J.; Long Island City, L. I.; Ogden, Utah; Chilhowee, Tenn.; Flushing, N. Y.

THE Editor of THE ENGINEERING AND BUILDING RECORD is always glad to receive items of news for the Contracting News Department. But such items are not considered news except when the prices and particulars of the award of a contract are given.

The announcement that ——— has sold ——— to ——— without giving the *prices* and particulars concerns only the buyer and seller. Such notices are always excluded, except in the case where a certain firm is stated to have taken a certain contract, the execution of which would require that they should buy certain materials. Such an item would be used if deemed of more than local interest, because it would suggest to some readers the possibility of their making a sale or securing a sub-contract.

BIDS OPENED.

MINNEAPOLIS, MINN.—By telegraph to THE ENGINEERING AND BUILDING RECORD, September 10, 1890:

"The Commission has rejected all bids for the construction of the superstructure of the court house and city hall, at this city, recently published. The architects have been instructed to prepare new estimates, the total cost not to exceed the sum of $2,500,000."

BOSTON, MASS.—The following bids for the construction of a wharf at Deer Island, were received by the Metropolitan Sewerage Commission, September 10: F G. Whitcomb, $11,736; Geo. H. Cavanagh, $13,900; John Cavanagh & Co., $14,200; Nay, Ellis & Kenrick, $14,430; Shaw & Miller, $16,300; C. T. Derry & Co., $16,980; J. N. Hayes & Co, $18,000

TACOMA, WASH.—Bids for the construction of the Pierce County Court House have been opened and the contract awarded to John T. Long, of Tacoma, for $270,000. There were eight other bids, the highest being $373,800. The contract includes all work except lighting and elevators.

GOVERNMENT WORK.

SACRAMENTO, CAL.—The following proposals for excavation, concrete foundations, stone and brick work of the basement area walls of the United States Post Office and Court House, at this place, have been opened by the Supervising Architect of the Treasury Department: Carlow Bros., Sacramento, Cal., $42,114; $42,804. Krenz, Berger & Harire, Sacramento, Cal., $40,251; M. J. Healy & Co., Loomis, Cal., $46,875; A. McElvoy & Co., San Francisco, Cal., $52,412; Frank Reid Forotcher, Lincoln, Cal., $59,600; Bassett & Towhey, Sacramento, Cal., $52,490; B. Krenzerbery, Sacramento, Cal., $49,000.

INDUSTRIAL.

WATERBURY, CONN.—The New England Engineering Company, of Waterbury, Conn., has been incorporated, to build, equip and operate electric light plants, railways, telegraph lines, etc.; capital stock, $40,000. A. M. Young can furnish details.

KANSAS CITY, MO.—The Kansas City Packing and Chase Refrigerator Company, of Kansas City, Kan., has decided to locate car shops in this city. The buildings will cover three acres of land. Plans and specifications are now being prepared for the new buildings, and as soon as they are completed and approved by the company ground will be broken for the foundations for the plant. It is proposed to expend the sum of $500,000 on the undertaking.

PEORIA, ILL.—Alderman Woolner can give information of a proposed 300-acre park for this city.

PROPOSALS.

(Continued from page ii.)

SEPTEMBER 1, 1800.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M., on the 30th day of September, 1890, for all the **LABOR AND MATERIALS** and putting in place complete the iron columns, iron floor and iron and wood roof construction, terra cotta arches, etc., for the U. S. Custom House, Post-Office, etc., building at PORT TOWNSEND, WASH., in accordance with the drawings and specification, copies of which may be had on application at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $200. The Department will reject all bids received after the time herein stated for the opening of the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be inclosed in an envelope, sealed and marked, "Proposal for the Iron Columns, Iron Floor and Iron and Wood Roof Construction, Terra Cotta Arches, etc., for the U. S. Custom-House, Post-Office, etc., at Port Townsend, Wash.," and addressed to JAS. H. WINDRIM, Supervising Architect. 15

SEPTEMBER 11, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M., on the 6th day of October, 1890, for all the **LABOR AND MATERIALS** required for furring, lathing, plastering, floor arches and concrete floors for the U. S. Post Office, etc., building at DAYTON, OHIO, in accordance with the drawings and specification, copies of which may be had on application at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $200. The Department will reject all bids received after the time herein stated for the opening of the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be inclosed in an envelope, sealed and marked, "Proposal for Furring, Lathing, Plastering, Concrete Floors, etc., at Dayton, Ohio, and addressed to JAS. H. WINDRIM, Supervising Architect. 16

PROPOSALS.

TO CONTRACTORS.

SEALED PROPOSALS WILL BE RECEIVED by the Committee on Buildings and Repairs of the Board of State Charities and Corrections for **BUILDING** the Male Wing of the new State Alms House at the State Institutions, CRANSTON, R. I., until 12 M., September 30, 1800.

The plans and specifications for the work can be seen at the office of Stone, Carpenter & Willson, Architects, 65 Westminster Street, Providence, R. I.

The Committee will receive bids for the Mason Work, Carpenter Work, Steam Heating, Plumbing, and Gas Piping, in one bid or in separate bids, and reserve the right to reject any and all bids as they may deem for the best interest of the State.

Per order of the Committee on Buildings and Repairs.

STONE, CARPENTER & WILLSON,
Architects.

17

BRIDGES, Atchison, Kan.—Proposals are wanted until September 16, for the construction of two iron span bridges. Address W. S. Parcell, Chairman County Commissioners, as above.

SCHOOL, Helena, Mont.—Proposals are wanted until September 20, for the erection of a school building at this place. Address F. W. Ellis, Clerk School District, No. 1, as above.

PIER, New York City.—Proposals are wanted until September 24, for preparing for and building a new crib bulkhead at Charity Hospital, Blackwell's Island, East River, and for removing the existing platform and crib bulkhead thereat. Address the Department of Docks, Pier A, North River, as above.

CITY HALL, North Bend, Neb.—Proposals are wanted until September 22 for the erection of a city hall building at this place. Address J. E. Newson, City Clerk, as above.

PUMPING ENGINE, Dallas, Tex.—Proposals are wanted until September 24, for furnishing one 10 000,000-gallon pumping engine, vertical compounding pattern. Address W. McGraine, City Secretary, as above.

BRIDGE, San Antonio, Tex.—Proposals are wanted until October 4, for the construction of a through truss, class "A," bridge, on the San Antonio River. Address Mayor Bryan Callaghan, as above.

WATER-WORKS, Toledo, Iowa.—Proposals are wanted until September 23, for the construction of a complete system of water-works at this place. Address Mayor A. M. Beal, as above.

WATER-WORKS, Rushville, Ind.—Proposals are wanted until September 16, for the construction of a complete system of water-works. Address Mayor Wilson T. Jackson, as above.

BRIDGE WORK, Reading, Pa. —Proposals are wanted until September 22, for the masonry abutments and wing walls for an iron truss bridge over Swatara Creek, in Tulpehocken and Bethel Townships. Address W. H. Fisher, County Commissioners' Clerk, Court House, as above.

BUILDING, Bridgeport, Conn. — Proposals are wanted until September 17, for the erection of a County Home building at Norwalk, Conn. Address Albert H. Beers, Architect, opposite depot, as above.

Building Intelligence.

We solicit from each and every one of our readers information relating to projected buildings in their locality, and should be glad to receive newspaper clippings and other items of interest.

MISCELLANEOUS.

BAYONNE, N. J.—The City Council has adopted plans for a new City Hall, subject to revision. Three architects competed, and L H Broome, of Jersey City, was successful. About $40,000 will be expended by the city for the purpose.

BRIDGEPORT, CONN.—Cor William and Barnum sts, br block of 7 tens; cost, $30,000; o, F Armstrong; a, M A Jenks; b, Jones & Hoffman.

Noble av, bet Maple and Arctic sts, br and stone school bldg; cost, $75,000; o, city of Bridgeport; a, Longstaff & Hurd; b, H M Purdy.

BOSTON, MASS.—590–94 E 7th st, 3 fr dwells; cost, $11,000; o, o, John R Cushing; a and b, W T Eaton.

Homes av nr Topliff st, 2 fr dwells; cost, $9,000; o, a and b, Andrew Crawford.

544–46 Commercial st, 2 br tens; cost, $12,000; o, Andrew Burnett; a, W H McGinty; b, John Kelley.

Blue Hill av, junction Walk Hill st, 2 fr dwells; cost, $9,000; o, Geo W Parker; a, J F Ober; b, R McDonald.

43 Charter st, and "rear of," 6 br tens; cost, $35,000; o, Nora Donahoe; a, J F Kelley; b, K Driscoll.

BUILDING INTELLIGENCE.

BOSTON, MASS.—95 Boylston st, br addn and alteration; cost, $8,000; o, F Haven, trustee; b, H McLaughlin.

Dorchester st and Vinton st, fr church; cost, $7,500; o, J H Storey and others; a, W H Besarick; b, not let.

100 Crawford st, fr dwell; cost, $7,500; o, F M Babcock; a, Brigham & Spofford; b, J A Corkham.

22 Victoria st, fr dwell; cost, $7,000; o and b, E McKechnie; a, E H Boyden.

Westville st nr Ditson st; 2 fr dwells; cost, $7,800; o, John Yates and others; a and b, H A Verge.

Topliff st nr Bowdoin st, 2 fr dwells; cost, $7,500; o, R Simpson and others; a, John H Keller.

Marmion st, nr Cornwall st, 6 fr dwells; cost, $9,000; o, Peter Barr; a, L W Bryant.

CANTON, O.—219 W Tuscarawas st, 4-story br business block; cost, $10,000; o, a and b, W L Davis.

N w cor 4th and Court sts, 3-story br business block; cost, $8,000; o, a and b, as above.

CINCINNATI, O.—The Fruit and Vegetable Commission men of Front and 6th sts have combined and will build a cold storage warehouse to cost $200,000. No plans have been made. John O'Moore & Co, of W 6th st, are interested in the project.

DULUTH, MINN.—A large flour mill will be erected at St. Louis, a small town just started a few miles above this city. It will cost $300,000. T A Bean, of Fairbault, Minn, is interested. An elevator, to hold a year's supply of grain, will be built near at hand.

NEWPORT, KY.—The old "Swift" rolling mills at this place have been purchased by capitalists, who will spend $250,000 in new buildings and machinery for a complete steel plate mill. Col A L Berry, Newport, Ky., can give particulars.

POTTSVILLE, PA.—1108 Mahvetonga, fr dwell; cost, $8,500; o, W W Foster; a, W P Hill; b, not let.

QUINCY, ILL.—Col W T Dowdall will rebuild his residence, destroyed by fire last week. It will be fitted up with modern improvements. The cost will probably be $50,000 or more.

ST. PAUL, MINN.—Dayton, nr Fish, 2 story fr dwell; cost, $8,000; o, R C Fish.

Summit, nr College, 2 story br ten; cost, $10,000; o, C S Carman.

BUILDING INTELLIGENCE.

SCRANTON, PA.—Br and fr school bldg; cost, $28,000; o, Scranton Board of Control; a, I J Williams; b, E G Hughes.

ST. LOUIS, MO.—Sidney and Liberty sts, br dwell; cost, $8,700; o, T Lang; b, E Paulus.

Westminister pl and Sarah st, br dwell; cost, $14,000; o, J J Philips; b, A Bauer.

3d st and Chouteau av, br warehouse; cost, $7,000; o and b, Cox & Gordon.

10th and Spruce sts, br warehouse; cost, $100,000; o, Tiffany R E Co; b, F C Bonsack.

Washington and Compton avs; br dwell; cost, $11,000; o, J Steer; b, sublet.

WASHINGTON, D. C.—1801–3 12th st, 2 2-story br bldgs; cost, $14,000; o, C W Handy; a, C V Trote.

615–21 22d st, 4 2-story br bldgs; cost, $12,000; o and a, R Sherman; b, W E Brown.

13th st, extended, 3-story br bldg; cost, $9,500; o, Wm Holoncad; a, H G Bonner; b, W T Garrison.

28–34 C st, 4 2-story br bldgs; cost, $16,000; o and a, same as above.

238–40 Dolan st, 2 2-story br bldgs; cost, $17,000; o and a, same as above; b, W T Garrison.

308–12 E st, 3 2-story br bldgs; cost, $9,000; o, E S Kennedy; a, same as above.

612–20 15th st, 5 2-story br bldgs; cost, $12,500; o, K Waloson; a, same as above.

615–19 Florida av, 3 2-story br bldg; cost, $15,000; o and b, W R Coon; a, N T Bealler.

1825 13th st, 3-story br bldg; cost, $11,000; o, J R McAsh; a, Pitney & Bradford; b, H F Getz.

1776 Q st, 3-story br bldg; cost, $60,000; o and a, T F Schneider; b, Emmet & Hinsley.

D st, bet 13th and 14th sts, 3-story br bldg; cost, $75,000; o, Albert Carey; a, A C Wagner; b, Wm Rothwell.

M st, bet 4½ and 6th st, 1-story br bldg; cost, $9,000; o, Chas Bailey; a, Glenn Brown; b, A J Fisher.

185 permiss less than $7,000 in value.

BUILDINGS.—There is nothing over $7,000 in value to report at the following places: Braintree, Mass.; Worcester, Mass.; Chester, Pa.; Ogdensburg, N. Y.; Allegheny, Pa.; Harrisburg, Pa.; Waltham, Mass.; Poughkeepsie, N. Y.; Easton, Pa.; Wheeling, W. Va.; Sioux City, Iowa; Topeka, Kan.; Denison, O.; Pottstown, Pa.; South Bethlehem, Pa.; Charleston, S. C.; Wilkes Barre, Pa.; Dayton, O.; Lancaster, Pa.; Savannah, Ga.; Fitchburg, Mass.

PAVEMENTS AND ROADS;

SOME PRESS COMMENTS:

A most creditable and seasonable compilation. It is decidedly the best collection of data on this important subject that has yet appeared in book form. —*Engineering News*, *June* 21, 1890.

* * * It should have a place, especially, in the offices of street and county commissioners, where its suggestions might soon contribute greatly to the commercial welfare, safety and convenience of thousands of communities in our land.—*Iron Age*, *June* 19, 1890.

A valuable manual.—*San Francisco Chronicle*, *July* 13, 1890.

The volume is one which has a practical value, and should be studied by all interested in road improvements.—*Troy Times*, *July* 21, 1890.

This book is very comprehensive in its scope and certainly supplies a long felt and pressing want. It ought to be studied by all who have to do with the construction of highways whether in city or country, as well as by councilmen, legislators, public writers and such as have a part directly or indirectly in the making of road laws, pavement ordinances, etc.—*Indianapolis Sentinel*.

PHILADELPHIA OFFICE, 1050 DREXEL BUILDING.

TERMS, $4 PER YEAR, IN ADVANCE.

25*s*. in GREAT BRITAIN. Other Foreign Countries $6.

Postage Paid.

British and Continental subscriptions should be sent to the London office. Checks, express money, and postal orders should be made payable to the order of THE ENGINEERING & BUILDING RECORD (New York).

Continental subscriptions are also received by F. A. BROCKHAUS, Esq., Querstrasse 29, Leipzic, Germany, and ASHER & Co., Unter den Linden, Berlin.

Subscriptions to the Continent of Europe and Australia, $6; China, Japan, Sandwich Islands, Mexico and Cuba, $6; South America, $6.

The date when the subscription expires is on the Address-Label of each paper, the change of which to a subsequent date becomes a receipt for remittance. No other receipt is sent unless requested.

Subscribers will please notify us *promptly* of any failure to receive the paper, and also of any change in their address.

Remittances are at the risk of the sender, unless made by registered letter or by check or money-order payable to THE ENGINEERING & BUILDING RECORD.

When a change of address is desired, both the old and new addresses should be given.

Discontinuances.—We must be notified by letter when a subscriber wishes his paper stopped. All arrearages must be paid.

The Courts have decided that all subscribers to newspapers are held responsible until arrearages are paid and their papers are ordered to be discontinued.

COUNTY ROADS.

IN view of the rapid progress that has been made in the improvement of county roads throughout the country during the past two years, it will be well to look over the field, and see whether any mistakes have been made and what can be done towards insuring the best results for the money expended.

Road making has been practiced from time immemorial, and the average road-master, or county legislator in the country, or street commissioner in the town has been so long looked up to as the one who knows all about it that he resents the idea that he can be taught anything, and considers the employment of an engineer an insult to his intelligence and a useless expense. Where provision has been made for the employment of county engineers, it has been in some cases considered as fully carried out by the employment of a land surveyor. In such cases an experienced eye at once detects a lack of proper regard to the topographical features of the country by an attempt to make the roads too level, resulting in defective drainage and often in a greater expense for grading than would otherwise be required. This shows itself also in the provision of very rigid specifications, followed by very poor inspection, of which latter the contractors are never slow to take advantage. Again, an inexperienced engineer, instead of leading the Board of Supervisors, or other body to whom he is responsible, is led by them. The contractor also soon sees with whom he has to deal, and easily convinces them that the best roads are to be made by an increased use of clay, and by the use of light rollers, and in various other ways obtains release from work he has contracted to perform. In such cases it seems to be forgotten that if the specifications were not to be insisted upon, then all other bidders for the work should have been furnished with such knowledge in advance of the letting, as it would often result in a substantial saving in cost.

We presume that under our system of government a town or county authority can spend and waste on road making money raised each year by taxes without any State control. But since a great many communities are likely in the future to incur indebtedness, that is, issue bonds the avails of which are to be spent in building roads, it is high time that legislation provided for some competent engineering tribunal to have at least advisory power, and who should be required to make periodical inspections and reports.

CHICAGO'S SMOKE TROUBLE.

CHICAGO is making a vigorous fight against the smoke nuisance. Judgment was rendered a few weeks ago against the Louisville and New Albany Railroad in seven cases for violating the smoke ordinance, and a fine of $50 was imposed in each case. The Pennsylvania and the Pan Handle roads were assessed $50 each in twenty-seven cases. The campaign of Chief Inspector A. Young, of the Chicago Health Department, against the offenders is based on three sections of the municipal code which declare as a public nuisance the emission of dense volumes of smoke from chimneys and smoke stacks, and provide a penalty of $50 on those responsible.

The smoke ordinance has been in effect for several years, but no strong effort has hitherto been made to enforce it. Now, however, that the World's Fair is to be held at Chicago, the measures are to be vigorously prosecuted. Since the beginning of April of this year a marked improvement is said to have already been effected in the condition of Chicago's atmosphere, and much better things are yet expected from the determined action of the authorities. No special smoke preventing appliance is insisted upon by the Health Department. All that it demands is that the smoke nuisance be abated, and owners of factories, tugs, locomotives, etc., are permitted to seek their own salvation. This, as THE ENGINEERING AND BUILDING RECORD has on several occasions pointed out, is the only proper way of obtaining relief from the smoke trouble. Rigidly enforce the law, and ways and means to comply with it will quickly suggest themselves.

IRRATIONAL BUILDING PLANS.

OAKLAND, CAL., proposes to build a fire engine-house, for which an appropriation has been made of $18,000. According to *The Tribune* of that city the Mayor recommends that this engine-house should be so planned that it may be enlarged from time to time to suit the purposes of a municipal building for the city. *The Tribune* seems to think that this is a very clever idea, and that it should commend itself to the people for its "practical good sense." It says that an engine-house is needed now. Before long some other department will need a new building and it can be added to the engine-house. If, therefore, proper plans be ordered and adhered to a "splendid city building will grow almost insensibly—a building which will not only be useful and convenient but possessed of architectural beauty, an honor and ornament to the city."

The Tribune should know that this is contrary to all past experiences, and, consequently, the reverse of practical common sense. It would be very much like having a suit of clothes made for the Mayor's small boy, if he has one, and then having them altered when a baby girl grows up so that they will suit her. If it is proposed to have an engine-house occupying a portion of a public building, the plans of the public building should be ordered now, and that portion of it intended to house the steam engine can be finished. This, however, is evidently impracticable in view of the amount of the appropriation. It will be much more sensible, therefore, to have the city build as good an engine-house as it can for the money at command, and when it needs another building have it designed by a skilled architect with sole reference to the use to which it is to be put.

WALTER HOWE AND JAMES GALLATIN.

NEW YORK CITY and the cause of sanitary reform has suffered a real loss in the recent death of two men in the prime of life—Walter Howe and James Gallatin. The former by his intelligent and earnest efforts in the Legislature secured important legislation for New York affecting the tenement house and street cleaning problems of the city, and since gave valuable services as one of the New Aqueduct Commissioners. James Gallatin, who died suddenly on the 17th inst. of heart disease, has of recent years been little before the public, but in the period from 1879 to 1882 he was the active member of the New York Sanitary Reform Society, spending a good deal of his time in Albany in the public spirited service of securing the passage of the Tenement House Act of 1879 and the Plumbing Law of 1881, which so largely increased the powers of the Board of Health. The early readers of THE ENGINEERING AND BUILDING RECORD will remember how the architectural competition instituted by it in 1878, for improved tenement houses, resulted in a popular agitation in the winter of 1879. Mass meetings at the Cooper Institute were held, and the tenement house evil was the subject for discourse in many churches of the city on a certain Sunday. It was then that the Sanitary Reform Society was formed, and Mr. Gallatin made its president and active officer. His private means enabled him to devote his time to the work of promoting that important legislation. Illness prevented his remaining at Albany at the critical stages of the plumbing law, but his services in the introduction of the measure and in enlisting influential support should not be forgotten.

PAYMENT FOR THE USE OF CITY STREETS.

THE joint special committee of the Boston City Council, composed of Aldermen William Power Wilson, John A. McLaughlin and Wesley A. Gove, Councilmen Bowdoin S. Parker, S. Edward Shaw, Isaac Rosnosky, Albert H. Hall and John F. Kinney, appointed to consider and report upon the advisability and method of securing some return to the city for the use of its streets by private corporations, having considered the subject, recently submitted a report to the Board of Aldermen.

In considering the subject, it was naturally deemed advisable to ascertain the experience and practice of other cities, and application was accordingly made to all the leading cities in this country and many of the cities of Europe, for such information upon the subject as might be of value to the committee. The particulars thus gathered would seem to show that Boston is much behind other cities in the United States in respect to solving the question of securing a return for the use of her streets afforded to private corporations, for in almost every one of the cities the corporations are required to make some direct return to the city for the privileges they enjoy in the public streets. This custom is so general that the claim that it would impose a burden upon corporations so serious as to impair their usefulness does not seem to have any force.

The local telephone companies of Amsterdam pay to the city, annually, 21½ per cent. of their gross receipts; in St. Louis, 5 per cent. of gross receipts, and in Philadelphia, $1 annually for each old pole and $5 for each new pole, used for the support of wires. Street railway companies also pay for their locations. In Amsterdam they pay 5 per cent. of gross receipts annually; in Baltimore, 9 per cent. of gross receipts, with an additional tax on each car; in Newark, 2½ per cent. of capital stock; in Providence, a certain fixed sum; in St. Louis, a percentage of gross receipts on a sliding scale; while in New York State all street railway franchises are now sold at auction for the highest offer above a certain fixed percentage of gross receipts.

The method most generally adopted is to require the payment to the city of a percentage of the gross receipts. This method may work to advantage in many instances, but in the case of a street railway, telephone or electric light company, having its tracks or lines in different municipalities, it would be difficult to adjust the rate proportionately. In addition to this, it is not always possible to ascertain what a company's receipts actually are. The special tax upon each car of a street railway company, such as is levied in Baltimore, might tend to deter the company from furnishing adequate and proper accommodations for the community, especially if the fee, as in Baltimore, is greater for a new car than for an old one. The system is also open to objection as not being applicable to all corporations.

As regards the auction system, which has been adopted in New York, the committee is of the opinion that it would not operate satisfactorily in Boston under the present state of affairs, particularly in reference to granting street railway locations. If a street railway extension became necessary, and the proposed new location was offered at auction, a system of competition would at once be introduced in opposition to the present system of monopoly, which has received the sanction of the Legislature. A further objection to the system appears to be that it would tend to prevent a judicious and necessary railroad extension, on account of the reluctance which a corporation would evince to risk its rights upon the uncertainty of a public auction. The committee is, however, favorably impressed with the method adopted in the city of Philadelphia, whereby a special annual fee is paid to the city for each pole belonging to the telegraph and telephone companies. The principle which underlies this system requires each corporation to pay a fixed sum for their special use of the public streets, and this sum is precisely proportionate to the extent of such use. The chief advantage of this system arises from the fact that it can be applied with equal fairness to each and every corporation enjoying the privileges granted them by the city. Thus a street railway company might be required to pay the city a fixed sum for each mile of track located in the streets; telephone and other companies, operating lines of electric wires, to pay so much for each pole erected; and companies making use of pipes and conduits, underground, a fixed sum per mile of pipe, etc.

The committee did not recommend any specific method of securing a return from corporations for the use of streets, but was instrumental in securing the passage of an order by which the Mayor is requested to petition the General Court at its next session for the passage of an act authorizing cities and towns to prescribe terms and conditions for the use of their streets by private corporations.

REPORT OF THE MISSISSIPPI RIVER COMMISSION.

THE annual report of the Mississippi River Commission for the fiscal year ending June 30, 1890, was received at the War Department at Washington a few days ago. It is dated June 30, but it has been delayed, probably owing to the fact that it is the largest and most exhaustive report yet made by the commission. It states that the work has been vigorously prosecuted during the year, and that the appropriations for the various localities are now practically exhausted. Complaint is made that funds for the expenses of the commission have been insufficient and personal inspection of the work by the Commissioners has necessarily been neglected. The flood on the Lower Mississippi interrupted the work in April, although the maximum discharge, including crevasse escape, was not so great as in 1882.

The lesson taught by the flood, says the report, is the same as that of other great floods—namely, the necessity of raising and strengthening the levees.

The survey of the river has been continued during the year. In general, the commission reports that the work of the year has been successful and the results satisfactory. Detailed reports as to the improvements in the several districts are transmitted from the engineers in charge, and there are also reports of the damages to levees and other improvements caused by the flood. The total expenditures for the fiscal year ending June 30, 1890, were $1,496,128, and there remained on hand July 1 a balance of $375,618. The estimates for the fiscal year ending June 30, 1891, are: For the commission, $35,000; continuing survey of the river, $150,000; improving river from head of passes to the mouth of the Ohio, $4,000,000; work at Hickman, Ky., $111,250; work at Greenville, Miss., $350,000; work at Vicksburg, Miss., $175,000; work at Natchez, Miss., $250,000; work at New Orleans, La., $200,000; improving Red and Atchafalaya Rivers, $350,000; total, $5.621,250.

Considerable space is devoted to the recent flood, and in this connection is presented a memorandum on the question whether building levees along a river causes its bed to rise. Various authorities are quoted to show that levees do not raise the bed of a river, and the history of several leveed rivers is cited in evidence. Among those are the Po, the Hoang Ho and the Yellow River. "The statement is often made," concludes the memorandum, "that leveed rivers raise their beds higher and higher as levees are raised, and hence that levees will give no permanent relief against overflow. These statements are usually made from theoretical opinions, and without a thorough knowledge of the theoretical side of the subject, and probably without any knowledge of the facts of experience, which alone can lead to conclusions entirely safe."

On the subject of outlets which have been proposed as a method of reducing flood heights on the Mississippi, the President of the Commission, Col. C. B. Comstock, says: "The immediate results on flood heights are so evident and so beneficial, when a large crevice is formed and the good results of an opening far larger than ever occurs, naturally seem so immediate and apparent that it is not strange that many persons look on them as the true remedy for great floods." He holds that the outlet system proposed would be not only useless, but in the end damaging, and as to the Lake Borgne outlet scheme in particular he concludes: "The reduction by any large amount of the flow of the Mississippi at Lake Borgne will be ultimately followed by a rise in the flood heights at that place, and a shoaling of the river at its mouth until the levees below Red River are much higher than they are now. About 600,000 cubic feet per second in the greatest floods should be allowed to go into the Atchafalaya basin, thus relieving the river below * * * A large diversion of flow from the Mississippi to Lake Borgne would also seriously diminish the depth of the present mouths of the river. For the following reasons, then, no important outlet as Lake Borgne should be either undertaken or permitted:

"1. It would for some years lower the floods at the outlet, accelerate velocities above it, and increase caving and the consequent destruction of levees.

"2. It would cause shoaling at the present mouth of the river.

"3. If both the new outlet and the main river below it remained important streams—that is, if neither of them closed itself under the action of natural causes—the flood heights of Lake Borgne and New Orleans would, after some years, be greater than they are now."

AN English contemporary says that the town with the cheapest public supply of electric light in Europe is Trente, in Austria. The station is owned by the municipality, and has at its disposal a large motive force from a waterfall under excellent conditions. The light is furnished to private consumers at the rate of 50 kreutzers (about 20 cents) per year per candle power, no regulation being made as to the number of hours. To put the electric light within reach of the poorer inhabitants, the house wiring, done by the town, may be paid for in annual payments. The station also supplies motive power.

CHARLES L. JUNGERMAN, City Engineer of Newport, Ky., was killed in an altercation with Thomas L. Reilly, a reporter for the Covington *Commonwealth*. Mr. Jungerman was 32 years old, a graduate of Vanderbilt University, and formerly employed on the construction of the Chesapeake and Ohio Railroad. Offensive articles in the paper were at the bottom of the difficulty.

PERSONAL.

MILLS G. VORIS, County Surveyor of Galesburg, Ill., was recently elected Assistant City Engineer.

THOMAS DUTCHER, of Far Rockaway, L. I., has been appointed superintendent of the Queens County Water-Works.

MR. A. KAHN, architect, with Messrs. Mason & Rice, Detroit, Mich., leaves shortly for an extended sketching tour in Europe.

R. W. EVANS, a graduate of the University of Illinois, at Champaign, has established himself as an architect at 511 North Center Street, Bloomington, Ill.

COLONEL R. T. SCOWDEN, City Engineer, of Louisville, Ky., has resigned his office and accepted a new position at Chicago, as engineer of the Chicago Refrigerator Company.

SIR BENJAMIN BAKER and Sir William Arrol, the well known English engineers, prominently identified with the building of the famous Forth Bridge, arrived at New York on the 14th inst.

ALLAN MACDOUGALL, of Toronto, Can., has been appointed to succeed the late City Engineer Charles J. Harvey, in the work of completing the sewer system of St. Johns, Newfoundland.

A. LOWTHER FORREST, recently Hon. Secretary United Arts Club, London, and in charge of the Adelphi Drawing Office, Charing Cross, has just opened a drawing office at 53 Devonshire Street, Boston, for the purpose of rendering drawings for architects.

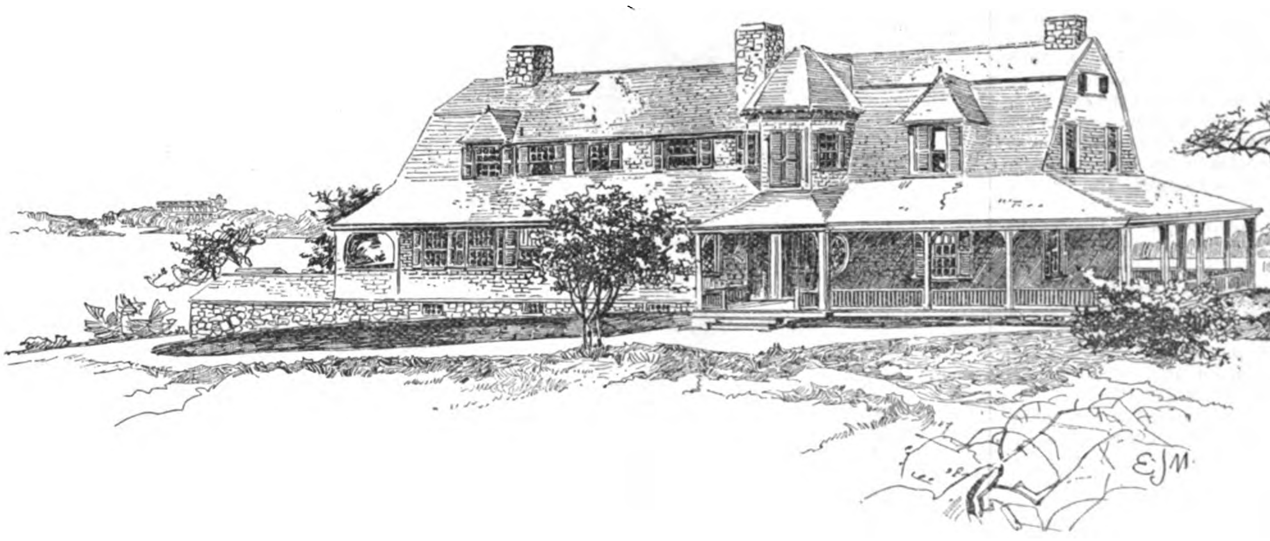
ENGINEERING SOCIETIES.

A REGULAR meeting of the American Society of Civil Engineers was held on September 17, Vice-President A. Fteley in the chair. Mr. C. B. Brush, as a member of the Local Committee of Reception, stated that arrangements were being made for the entertainment of the members of the British Iron and Steel Institute, who are expected to visit this country during September and October. The preparations are in the hands of the American Institute of Mining Engineers, and a bureau of information and general headquarters will be established at the Park Avenue Hotel, New York, on the last of this month. The programme will comprise meetings and local excursions in New York, a trip to Pittsburg, Chicago, Alabama and the Lake Superior region, and a banquet and reception after their return to New York.

Acting Secretary J. F. Crowell read a discussion, by Max O. E. Schmidt, on the recent paper by W. Barclay Parsons on "Railways in Mexico." Mr. Parsons replied to the discussion, and some further remarks were made by P. F. Brendlinger and J. F. Flagg. The Secretary read a discussion by O. F. Nichols on the paper by F. W. Watkins on "Tunnel Surveying on Division No. 6, New Croton Aqueduct." Mr. Watkins replied to the discussion, and, at his request, A. Fteley described and illustrated, by blackboard diagrams, an instrument that he had devised and used for graphically recording the cross-sections of the Croton Aqueduct, and for detecting settlements and distortions of the masonry. The instrument consisted essentially of a slotted radial arm pivoted on the face of a board which was set at the center of the required cross-section and in its plane. A printed diagram of the correct required cross section to about $\frac{1}{10}$th scale was placed on the board, concentric with the pivot of the arm and the center of the arch. The outer end of the arm carried a small contact wheel, and a pencil was attached to the arm where it should intersect the arch line on the printed diagram. When the contact wheel was passed around the arch soffit, the pencil traced a corresponding line on the diagram, and as its irregularities were to the natural scale radially and diminished laterally, while the diagram was at a reduced scale, it gave the effect of greatly magnifying distortions that would be imperceptible to the eye. It proved very convenient and valuable, an assistant and two laborers being able to take 50 or 100 cross section diagrams in one day with it.



HOUSE AT PORTSMOUTH, N. H.—LONGFELLOW, ALDEN & HARLOW, ARCHITECTS, BOSTON, MASS.

Mr. Fteley also related some experiences of the cracking of the invert from settlement, and the construction of a section on a long 50-foot embankment which was crowned 1 inch at the center. After the aqueduct had been constructed a long time over it, the settlement was not more than $\frac{5}{8}$ of an inch and the masonry was intact. In discussing the wonderful endurance sometimes secured in thin masonry, Mr. Fteley referred to a well-known example of an elliptical brick sewer between Boston and Charlestown, Mass. It was about 8 inches thick and 6½x5½ feet, set in a concrete cradle that rested on the caps of a double row of piles, driven pretty closely together, within the width of the sewer. The sewer was built for a special purpose, and usually ran full to within perhaps 6 inches of the top. After many years a careful examination was made of some bad breaks that were known to exist in the invert. It was found that the overhanging ends of the timber caps had broken at the piles, and that the dislocation had broken the sewer ring in three places, at the center of the top and at the bottom, each side of the center. The settlement and distortion had produced a reversed curve at the bottom and a pointed arch at the top, so that the cross-section resembled a heart, apex up, with cracks open 4 or 5 inches in the bottom loops; yet the sewer performed its duty, and after equilibrium was destroyed by emptying it, it held together to be repaired. Mr. Fteley's description was briefly discussed by L. L. Buck and F. S. Washburn.

MR. CHARLES PAINE, as chairman of the nominating committee of the American Society of Civil Engineers, has issued a circular letter to the members of the society, requesting them to propose, before October 1, on an inclosed blank form, the names of three members for each of the elective officers—viz.: President, vice-presidents, secretary, treasurer and directors. The committee will be materially assisted in their efforts to ascertain the wishes of the society at large, if all members will make careful responses to the invitation.

THE BOSTON SOCIETY OF CIVIL ENGINEERS held a regular meeting on Wednesday evening September 17, at 7.45o'clock, with President Clemens Herschel in the chair, S. E. Tinkham, Secretary, and about 35 members and visitors present. The following were elected members: Fred Vincent Fuller and James H. Stanwood, both of Boston, and Edward L. Ross, of Indian Orchard, Mass. A communication from the Western Society of Engineers in relation to the International Engineering Congress to be held in Chicago in 1893 was presented, and it was voted that the question of sending a delegate from the Boston Society be referred to the Board of Direction of the society.

John R. Freeman gave some interesting "Notes on English Mill Construction," illustrated with black board drawings, showing some details of different forms of floor construction, etc. M. M. Tidd gave some particulars of floating stone bridge piers into position by means of caissons. Both papers were informally discussed.

THE WESTERN SOCIETY OF CIVIL ENGINEERS contemplate the holding of an international congress of civil engineers in connection with the World's Fair at Chicago. A committee of the Western Society appointed to consider the question recommends that the engineering societies of other countries be asked to send delegates, and that the governments of the world should send representatives. It was proposed that delegates from the engineering societies of this country and Canada should meet in Chicago about October 1 of this year for the purpose of formulating plans for holding an international congress.

GEORGE KOPP, an employee of the United States Electric Light Company, at New York, was killed on the night of the 15th inst., by coming in contact with a poorly insulated wire while putting new carbons in an arc lamp.

NEW ENGLAND WATER-WORKS ASSOCIATION.

THE fall meeting of the New England Water-Works Association included an excursion to the White Mountains, in which the Boston Society of Civil Engineers also participated. The party, numbering 56, including members and friends with ladies, left Boston Saturday morning, September 13, arrived at Wolfeboro Junction in time for lunch, and reached the Crawford House that evening. Here Sunday was passed, the feature of the day being a ride up Mount Willard. On Monday the party went to the Profile House, enjoyed a carriage ride to the Flume in the afternoon, and on the next day proceeded by stages to North Woodstock, where the train was taken for Boston.

PROTECTION OF MINE TIMBERS FROM DECAY.

THE German Government mine Altenwald, near Saarbrucken, has, since 1888, conducted a series of experiments to ascertain the most effective means to prevent from decaying the pine timbering, which is subject to great pressure in the airways. Lime, coal tar, tar and carbolineum were tried in such a manner as to enable a comparison of their relative protective value. The results, as published in *Ztsch. f. d. Berg, Hutten u. Salinenwesen*, show lime to be the weakest. Coal tar preserved the outside of the timber, while the core was found completely decayed. Carbolineum proved by far the best, and is now being used on much of the timbering in that mine. The mine timbers, made of wood peeled and dried, are twice painted over with the carbolineum above ground, and require each, when 2.5 meters long and 0.25 meter in diameter, in the first application 4.5 kilogramme, and in the second 3 5 kilogramme, so that, at a price of 34 5 pf. per one kilogramme, the total cost was: For material, 48.3 pf., and for labor, 14 pf., or altogether about 15 cents.

THE case of Architect E. V. Koch, of Milwaukee, Wis., against Dr. T. W. Williams was decided in favor of the plaintiff last week. The plaintiff had furnished defendant with plans and specifications for a block of flats. The building was afterwards erected, but entirely different plans than those submitted by the plaintiff were used. Plaintiff thereupon sued for remuneration for his work, and also applied to have his claim made a mechanics' lien on the building. The judge found that plaintiff was entitled to remuneration, the amount to be ascertained later, but that he was not entitled to a mechanics' lien.

THE subject of coal waste is to be investigated by a Pennsylvania State Commission. The waste arising from producing and marketing coal, also the utilization of all kinds of wastes, come within the scope of the inquiry.

A RATHER extraordinary project for power distribution is at present under consideration in Saxony, Germany. It is proposed to establish near the city of Dresden an immense electric central station to furnish high-tension currents for lighting and power to 168 small towns and villages in the territory circumscribed by the towns Meissen, Freiberg, Pirna, Schandau, Sebnitz and Radeberg,

CORROSION OF CAST-IRON WATER PIPES.

In a paper on the Sheffield, England, water works, read a few weeks ago before the British Institution of Mechanical Engineers, Edward M. Eaton, the chief engineer of the works, stated that he had been troubled by the formation, on the interior of the pipes, of "tubercles," the origin of which was obscure. Writing to *Engineering* on this subject, Charles King, of Winterthur, Switzerland, says:

"Speaking before the Institution of German Engineers in Berlin, Herr Oesten, the chief engineer of the water works of that city, referred to the same matter, and put forth the following theory in explanation of the same: The knotty substances are built up in layers, and in every case the outermost layer is the hardest and strongest, while those towards the inside are much softer, and the interior is generally filled with a pasty mass. By taking up oxygen from the water the inside skin of the pipe increases in volume and forms into buckles in order to make room for the increased area, and the outer layer is that which is most highly oxidized. This layer takes up then primarily the oxygen, but because behind it there are layers not so fully oxidized, the latter again extract the oxygen from the former, so that the oxygen gradually travels from the outside to the inside of the 'tubercles.' For this reason the outer layer is compelled to remain at a lower grade of oxidation than those on the inside, and so it comes to pass that the rust on a fresh cut-out piece of pipe has always on the exterior a brackish and never a red-brown color, which latter it, however, assumes after exposure to the atmosphere when the process of oxidation completes itself.

"In proof of the above theory Herr Oeston proposes the following simple experiment: If freshly chipped off iron rust is washed out of a pipe, and, in the condition of mud, is put into a bottle which is quite full and air-tight, then in a short time the dirty-colored matter adheres to the sides and bottom of the flask. If we now allow air to enter, the rust on the sides of the bottle will assume a reddish tint, and if the operation goes on long enough the upper layer at the bottom will do the same. If we then close the bottle again and let it stand the red color will gradually disappear, and by a retrograde process the red oxide deteriorates to a lower stage of oxidation once more. The oxygen has been taken up by the lower layers without having been able to complete the process of oxidation.

"By coating the pipes on the interior surface in the usual manner the process is delayed but not prevented. The coating is never perfect, and in the course of time becomes brittle and cracks, exposing the cast-iron surface to corrosion in different parts, and here the formation of the knotty substances begins. Blind pipes, which have no through current, often suffer much less from corrosion than those which have a constant circulation, and consequently receive a greater supply of oxygen.

"In order to clean the pipes Herr Oesten cuts out a short length at two different points sufficient to allow the introduction of mechanical scrapers which travel from one opening to the other. In this way he has during the last three years cleaned out over 40,000 meters of piping, which was laid down from 25 to 34 years ago, at a gross expense ranging between 8½d. to 1s. per meter, the diameter of the mains being mostly 3 inches and 4 inches."

DEFECTS IN WOOD STAVES OF WATER PIPES.

In a recent report on the destruction of pine staves in the clear water pipe of the Ottawa water-works system, and of oak slats in a rack through which the water passes before entering the turbines, James Fletcher gives the following particulars:

"The condition of these specimens is, briefly, as follows:

"1. The wood of the pine staves is almost uniformly one inch and a half in thickness, in a few places possibly one-eighth of an inch less, and perhaps a little thicker where knots occur. At the original point of contact, where the staves touched on each side those next to them, the edges, particularly of the inner surface of the pipe (but also to a much less extent of the outside as well) are much eroded between the staves for some distance towards the exterior of the pipe, causing a deep groove varying between one-quarter and three-quarters of an inch across at its greatest width. In depth this groove varies in most places between one quarter of an inch and one inch; but at many points it has extended right through the wood to the outside, causing large holes from four to six inches in length by one wide, thus entirely defeating the ends for which this pipe was originally intended.

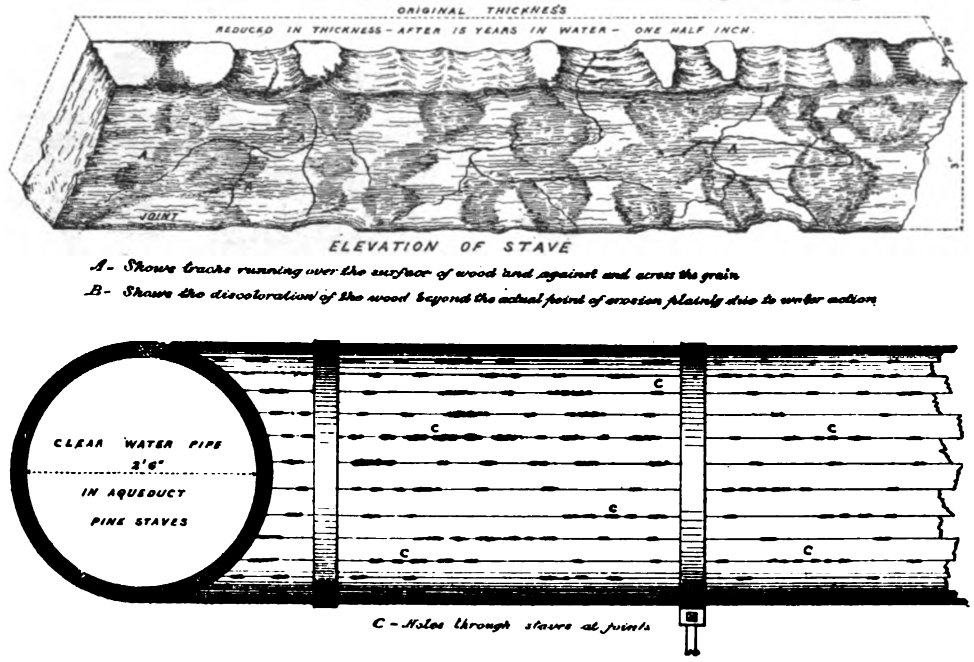
"If these staves were, as stated, two inches in thickness when put down, it is evident that by some means about half an inch of the wood has been removed during the 15 years which have elapsed since the pipe was laid down in the aqueduct.

"In answer to your inquiry as to the probable cause of this diminution in the substance of the pipe and the probability of its being due to the operations of aquatic insects, I take the liberty of drawing your attention to the following points.

"The condition of the wood of the staves is as follows: The wood itself below the surface and between the staves where these were in close contact, is perfectly sound, of good color, and not injured in any way. On the other hand, all surfaces which have been exposed to the action of the water, whether inside or outside the pipe or in the grooves eroded between the staves, are discolored and in a semi-decayed condition—*i. e.*, the wood is so soft and rotten that it can be easily removed with the finger nail to a depth of at least one-sixteenth of an inch. In and upon this thin layer of half-decayed wood, the larvæ of various kinds of aquatic insects have taken up their abode and some have made use of it as food, as is plainly seen by the numerous tracks which have been eaten out all over the surface. These tracks are irregular and winding in their course, going in all directions, as often across the grain of the wood as with it. They do not penetrate the solid wood, but frequently reach down to it and run along on the surface. The same track sometimes runs in one direction for some distance and then doubles back on itself and runs the other way: a fact which entirely disproves the suggestions which have been offered by some that the whole of the injuries to the pipe, as well as these tracks, are the effects of friction, current or suction. One particular track was observed to start on the inside of the water pipe and work its way through one of the large holes out on to the outside surface. It is a notable fact that these tracks run over the whole surface of the wood even to the bottom of every little depression. I believe that the softened condition of the surface of the wood is due to the action of the river water and I find that, in some places, where the eroded groove stretches out in points from the inside towards the outer surface of the pipe, there is generally a discoloration of the wood beyond the point where the surface is actually eaten away, as if decay had already begun although the tissues of the wood are still unbroken, but showing plainly that the water had effected an entrance between these discolored surfaces. It is generally perceptible that there is in such spots a slight inequality of the exposed surfaces of the two contiguous staves which may have been caused either by some slight unevenness in the planing of the wood at the time of building the pipe, or possibly from the wood having swollen unequally when it was placed in the water.

OTTAWA WATER WORKS

SKETCH SHOWING DEFECTS IN WOOD STAVES OF CLEAR WATER PIPE



A- Shows tracks running over the surface of wood and against and across the grain

B- Shows the discoloration of the wood beyond the actual point of erosion plainly due to water action

C - Holes through staves at joints

"I am informed that at the time the pipe was constructed the edges of the staves were flush both inside and outside this pipe, which was built like a barrel, with the staves slightly beveled at the edges, so as to procure the tubular shape, and that the whole was held together by strong iron hoops. This being the case I can only suggest as a reason for the eroded groove being so much wider and deeper on the inside of the pipe, that unless the angle of the beveling were perfectly true, the outer edges of the staves would be much tighter clamped together by reason of the iron hoops outside.

"I would suggest then, as the cause of the destruction of the clear water pipe—first of all—the decaying of a very thin layer of the surface of the wood through the chemical action of the river water; and, secondly, the breaking up and removal of this decayed surface by aquatic insects, so as to constantly expose a new surface of the wood to the action of the water.

"It is probable that both of these operations were assisted by the strong current in which the pipe was situated, in the first place, by forcing the water into every minute crack or crevice, and then by carrying away fragments of the surface loosened or undermined by insects.

"I am aware that it is held by many that sound pine wood kept constantly submerged beneath the surface of water is practically indestructible, and I have no doubt that under some circumstances and for some purposes this might be the case. It must, however, be remembered that more or less air, varying with the circumstances, is always dissolved in water. I am under the impression that water containing a large quantity of air, as the water of the Ottawa River necessarily does, after passing down the Deschenes rapids, would be more destructive to wood submerged in it than water containing less oxygen.

"With regard to the insects found upon the staves submitted to me they were for the most part predaceous larvæ of beetles and dragon flies or allied insects. I might mention that none of these insects have ever been known to bore into sound wood, but feed exclusively upon decaying vegetable tissues in water, and their occurring in large numbers upon the clear water pipe may possibly be due to the unusual quantity of decaying bark which I am informed lies in the Ottawa River near the inlet of this pipe, and which would attract these insects as a suitable breeding ground. They are in no way related to the ordinary timber boring beetles which are so destructive to standing timber and manufactured lumber in all parts of the world.

"2. The oak slat taken from the rack near the pump house, and which had only been in the rack for ten years, was proportionately much more destroyed than the pine staves. The slats were half an inch in thickness by four inches in width when put in the rack; but many of them are now so seriously injured that it is necessary to replace them. In most of the slats the greater part of the wood has been entirely consumed."

NOVIA SCOTIA'S SHIP RAILROAD.

Sir Benjamin Baker, one of the engineers of the Forth Bridge, is paying a flying visit to this country as chief engineer of the English syndicate which bought the Hudson River Tunnel. He is here also for the purpose of inspecting the work on the new ship railway from the Bay of Fundy to the Gulf of St. Lawrence, which is now in course of construction at Amherst, Novia Scotia. He is chief engineer of the railway, and represents the syndicate of English and American capitalists who control the scheme. The New York *Tribune* reports him as having said:

"The project of a ship railway is by no means new. It has been mooted any time within the last thirty years. Captain Eads, of Mississippi jetty fame, proposed it many years ago as an alternative to the Panama Canal. M. Eiffel, who built the great exhibition tower, and has contracts for locks on the Panama Canal, lately consulted with me as to the feasibility of converting the Panama Canal into a ship railway. Thus the works now going on at Amherst is exciting profound interest.

"The earthworks and masonry of the docks of this ship canal are being constructed by an American firm of contractors, Messrs. Dawson, Symes & Usher. The machinery, including powerful hydraulic lifts, each capable of hoisting to a height of 40 feet the total weight—3,500 tons—of a ship and cradle, is being manufactured by Easton & Anderson, of London. About two-thirds of the railway and docks are finished. Nearly the whole of the machinery has been made and the greater part of it shipped to this country.

"The railroad will be about 17 miles in length. The locomotives for hauling the ship over the railroad are exceptionally powerful, being 8-wheeled tank engines, each weighing 80 tons. The saving of time in transit will be enormous when you consider that it now takes a ship three days to go from the Bay to the Gulf, while the time occupied on our road will be about two and a half hours. We have now 1,400 men at work and hope that the railway will be opened in the spring of 1892, if not earlier. The Canadian Government has guaranteed the company $170,000 a year for twenty years."

An electrical paper points out that in Europe bronze has, in a great measure, superseded iron and copper in electrical appliances.

THE DALMARNOCK BRIDGE, GLASGOW.

In a recent issue of London *Engineering* considerable space is devoted to the illustration of the permanent structure and air locks of the Dalmarnock Bridge. There are some features of interest shown by the figures here reproduced—viz., the heavy ballasted paved roadway and the high iron caissons.

The Dalmarnock Bridge is a steel girder road bridge over the River Clyde, at Glasgow, and consist of five spans of 54 feet 8 inches each. Figure 1 shows a half cross section of the bridge which is symmetrical about its center line; A B and C are main girders; D D are floor joists alternating with T bar beams E E that help carry the 3/8-inch buckle plates G; H is a Lindsay's patent flooring, and I is a 1¼-inch gas pipe drain; J is an ornamental cast-iron balustrade, and K is an ornamental paneled cast screen concealing the face of the outside girder.

The bed of the river consists of fine running sand and muddy clay, extending down to the carboniferous sandstone at a depth of from 50 feet to 60 feet below low water. The permanent caissons are shown in Figs. 7 to 10, and are made of sufficient height to reach from the rock up to low water, and above this temporary lengths of caisson are fixed to allow of the masonry of the piers being built above high water. There are two shafts in each caisson communicating with the working chamber, one for men and the other for materials, on which the airlocks are fixed.

Fig. 1

The sides of the working chamber and enough of the caisson above it to give sufficient weight, are filled with Portland cement concrete when the sinking is commenced, and more concrete is added as it proceeds. The excavation is carried on until the cutting edge of the caisson has a fair bearing on the rock all round, and the area inside is then leveled and concrete filled into the chamber, rammed hard up to the roof, and finally grouted through the shafts. The remainder of the caisson up to low water is also filled with concrete, and the masonry of the piers commenced upon it.

Messrs. Crouch and Hogg, MM. Inst. C. E., are the engineers of the bridge, and the contractor is Mr. A. H. Boyle. The cost of the work will be about £30,000.

Up to the present time the sinking of two of the caissons has been completed, and that of the other two is in progress. The masonry of the abutments and of one of the piers is completed, and the girders laid over one span. It is expected that the bridge will be completed during the ensuing summer.

MAGNETIC IRON OXIDE FILTERS.

A process of manufacturing filtering material is described by *The Engineering and Mining Journal* as consisting essentially in reducing ferric oxide by heating it in contact with gaseous fuel. Small pieces of iron ore, preferably hematite, are packed into a retort heated externally, preferably by producer gas. When the charge is at a cherry-red heat, gaseous fuel is admitted into the retort and brought into thorough contact with the ore. At the end of four or five hours, if the exit gas be inflammable, the process is finished, and the charge raked out and allowed to cool. Ordinary coal-gas or other gaseous fuel may be used instead of producer gas. The magnetic oxide so produced is available for filtering water, sewage, sugar syrups, alcoholic liquors, etc.

The extraordinary scheme of bridging the channel between France and England does not seem to have altogether died away, and soundings have been recently taken at Folkestone, England, with a view to ascertaining what kind of foundations would be available, the results being, it is stated, satisfactory.

A SYSTEM OF INCLINED PLANES FOR BOATS.

In a paper on the above subject, presented by M. A. Flamant at the Fourth International Congress on Inland Navigation, recently held at Manchester, England, it was pointed out that among the apparatus for transferring boats engaged in inland navigation from one level to another, the inclined plane possesses an advantage over the vertical hoist, inasmuch as it is applicable to much greater differences in height.

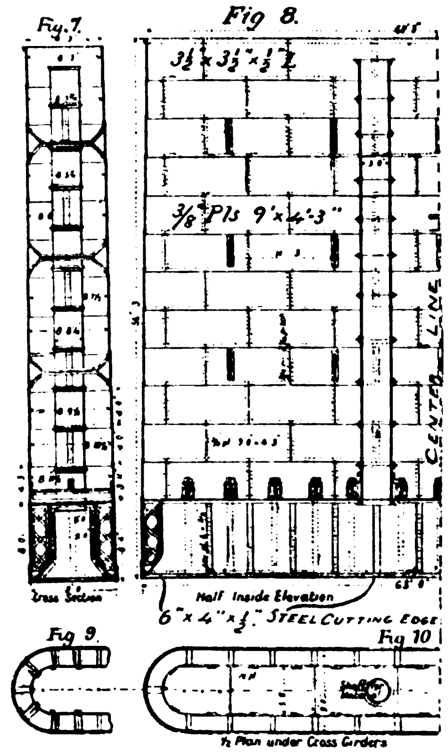
All inclined planes employed or proposed up to the present time are so arranged that the boat is conveyed lengthwise. This prevents the gradient being greater than one in eight, or one in ten, for if it is, and the chamber for receiving the boat is somewhat lengthy, its hinder portion is raised high above the ground, and the stability of the whole is considerably reduced. The inclined plane equaling in length eight or ten times the vertical height to be attained, calls for the exertion of considerable power to overcome the passive force of the chamber and necessitates the use of powerful machines. This difficulty, however, is avoided by placing the chamber crosswise, that is to say, by making its greatest dimension parallel with the horizontal of the inclined plane. Under these circumstances we may have a much steeper incline and at the same times reduce the length and lessen to a very great extent the passive force, which is decreased partly by the diminution of the component force of the weight to be raised, and partly by the diminution of the distance to be covered. The increased gradient of the plane reduces in a large measure the time occupied in the maneuver, and thus augments the traffic capacity of the apparatus.

The transversal disposition of the chamber also offers another improvement, which, so far as regards the rapidity and facility of the maneuvers, is of very great importance. In inclined planes arranged longitudinally, as also in vertical hoists, the movable chamber, having arrived at one extremity of its course, can only be opened and put into communication with the canal at one of its ends. The boat which it contains has to leave it entirely and pass out of the way before the one waiting to replace it can enter. A loaded boat entering the chamber can only do so by forcing the water round its sides and out at the entrance, and consequently the maneuver always occupies considerable time in spite of any mechanical means of traction we may apply.

When the position of the chamber is transversal, the way of procedure is to place it, at either end of its course, against the side of the canal, and it is only necessary to have the canal prolonged for the length of a boat on each side of the inclined plane, to enable the chamber, opened at both ends, to communicate freely with the canal and allow one boat to leave at one end whilst a second enters at the other without any repelling of the water and with the greatest facility. The time occupied at either extremity is lessened by more than one-half, and thus the traffic capacity is increased in a very high degree.

The Fives-Lille Company have had under consideration a complete project for an inclined plane on these lines, for the purpose of overcoming a difference in level of 30 meters. The gradient of the plane has been fixed at 1 in 2. This gradient might be increased so as to diminish the passive force to be overcome, but it would be requisite then to increase also the strength and the weight of the chains used in moving the chambers, and it would be very difficult to provide an efficient safeguard against their rupture. With the gradient adopted, however, the chains are restricted to moderate proportions, and a toothed rack, solidly fixed in the inclined plane and supplied with a catch which only comes into operation in case of a chain breaking, is sufficient to maintain the chamber at any height and prevent disaster.

The inclined plane under the consideration of the Fives-Lille Company is double, and is intended for a waterway over which there is a great amount of traffic; it has two chambers, each sufficiently large to receive the boats navigating the network of waterways in France. These boats are 38.50 meters long and 5 meters broad, and they draw 1.80 meters of water with a cargo of about 300 tons. The two chambers are in equilibrium, that is to say, they are suspended by chains running through pulleys fixed on the upper portion of the plane. In order to provide for the varying weight of the chains and for preserving the equilibrium of the chambers in any position, the idea occurred to M. Bassères, engineer to the Fives-Lille Company, of adopting for the profile of the inclined plane not a straight line, but a concave arc, the span of which has a gradient of 1 in 2, and the pitch, necessary for the height and for the weight of chain to be compensated, does not exceed 45 centimeters. The result is that at the two extremities of the chamber's course the sides are not strictly vertical, nor is the bottom quite horizontal, but the incline of the sides does not exceed one-fiftieth and the boat is not prevented from floating freely. Under these conditions, the system being statically in equilibrium in all positions, the resistance to be overcome in putting it in motion is constant, and the necessary power can be obtained by the addition in the higher chamber of a volume of 120 cubic meters of water, which corresponds to a height of about 50 centimeters in the chamber.



DALMARNOCK BRIDGE

The working of the inclined plane is thus accomplished in the same way as the vertical hoist without the introduction of any special machine. The simultaneous movement of the chambers can be effected, without the addition of water, by means of a steam engine and a special traction chain. A machine of 180 or 200 horse-power would be necessary.

NOTABLE APPLICATION OF WATER POWER.

Some interesting features, says the San Francisco *Mining and Scientific Press*, are noted in the power equipment of the Treadwell Mill, Alaska—the largest quartz mill in the world, consisting of 240 stamps, 96 concentrators, 12 ore crushers, etc., and requiring about 500 horse power. All of this machinery, covering several acres of ground, is run by a single wheel 7 feet in diameter, operating under a head of 490 feet, making 235 revolutions, and using 630 cubic feet of water per minute, this being discharged through a nozzle 3.31 inches in diameter; with a 4-inch nozzle this wheel will work up to 735 horse-power. Regulation is afforded by the use of a deflecting nozzle operated by a hydraulic governor; the nozzle is about 4 feet long with a ball joint at the butt end, and to the discharge end is attached by lever connections an automatic hydraulic regulator, which varies the amount of water applied to the wheel as may be needed to adapt it to varying loads—a device which affords a peculiarly simple, sensitive and satisfactory regulation. With such an arrangement, and in such a location, the advantage of water power is conspicuous. Thus the wheel above mentioned weighs but 800 pounds, and the entire equipment, embracing shafts, boxes, driving pulley, etc., only about 4,000 pounds; on the other hand, a steam machinery plant, to give the maximum capacity of such a wheel, would not weigh less than 200 tons, and the expense of running such a plant would be almost immeasurably greater.

A FRENCH BRIDGE-TESTING DEVICE.

THE June number of *Les Annales des Ponts et Chaussées* contains an interesting description and illustrations of a simple instrument for measuring distortion, especially intended for use in testing iron and steel bridges. The machine is screwed to small holes in the members to be tested in the structure, and magnifies the change of distance between two points by the action of a piston, or diaphragm, of large cross section, whose movement forces a liquid into a glass tube of very small caliber. The record and description of some tests and experiments made with the instrument are given.

LAFAYETTE COLLEGE, Easton, Pa., has established a new department for highway construction. Tuition is free to residents of Pennsylvania, who are nominated by county officials of that State.

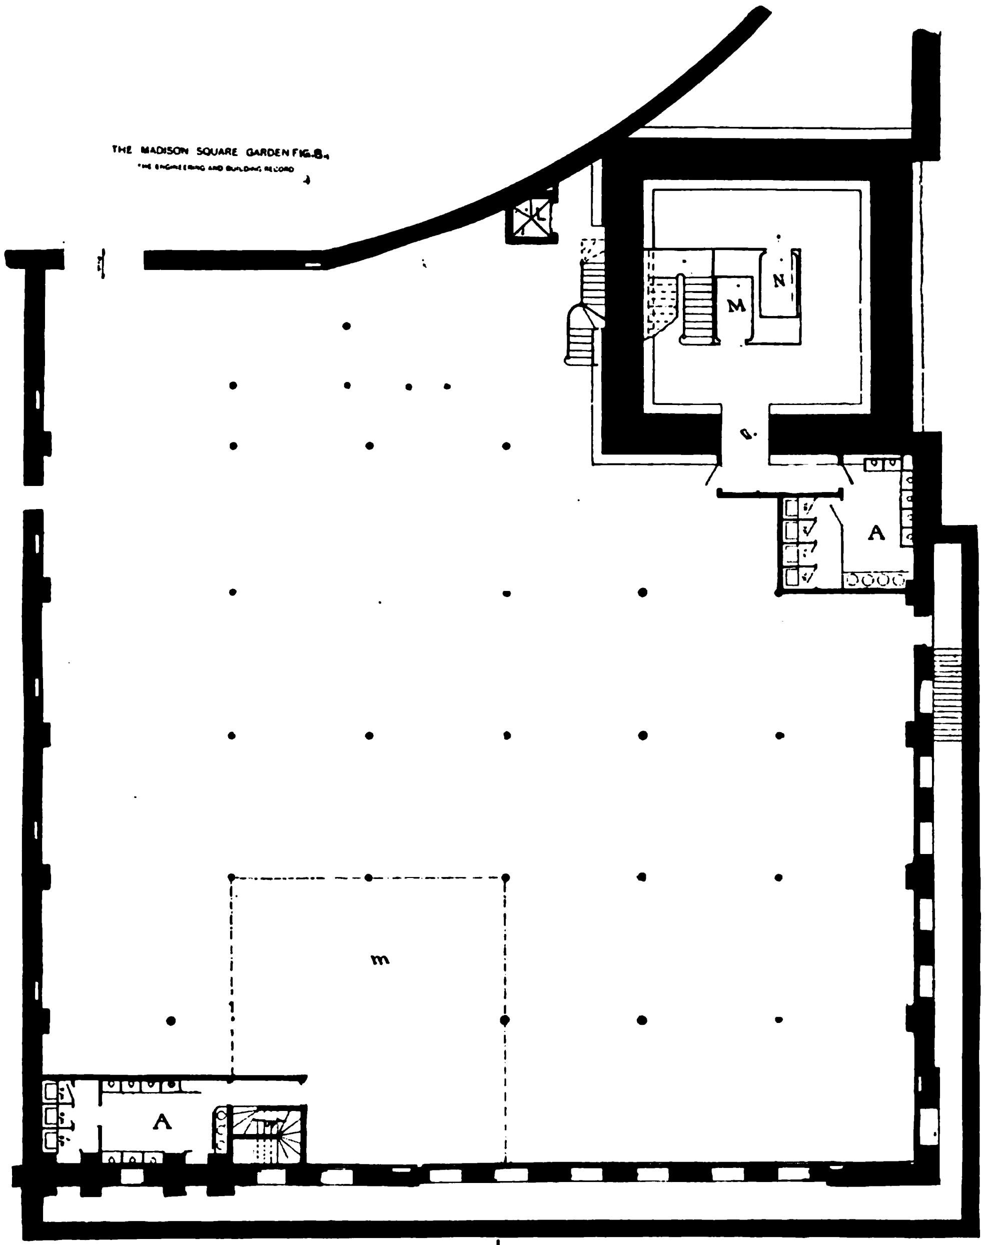
THE MADISON SQUARE GARDEN.

PART II.—BASEMENT, HORSE STALLS, ARENA AND AUDITORIUM OF AMPHITHEATER. RESTAURANT, BALL ROOM AND CONCERT HALL, GALLERY AND FOYER.*

FIGURE 7 shows half plans of the basement horse stalls and of the arena of the amphitheater, immediately above. Both plans are substantially symmetrical about their longitudinal axes.

Figure 17 is a general plan of the amphitheater, arena and auditorium, showing the arrangement of the lower seats and boxes. Ordinarily the performers enter the arena at A, and a tier of seats and boxes is placed at A B, but these are movable, and the whole space may be opened and left unobstructed except by two columns. The audience enters on each of the four sides of the building. Above the seats, shown in Fig. 17, on all sides of the amphitheater, is a continuous gallery, having four rows of seats, and carried on floor beams whose outer ends are built into the walls, and whose inner ends project cantilever wise over the columns. Above this gallery is a promenade gallery, also continuous around the amphitheater, and having one row of seats around its inner edge.



THE MADISON SQUARE GARDEN FIG. 8.
THE ENGINEERING AND BUILDING RECORD

Figure 8 shows the basement plan of the concert hall. L is a freight elevator; M and N are concert hall and roof garden elevations; A A are men's toilet rooms; M is the location of the ventilating blowers.

Figure 11 is a plan of the restaurant on the ground floor. The reference letters A, L, M and N have the same meaning here and in Figs. 9 and 10 as in Fig. 8. B is an employees' water-closet; D, W, etc., are dumb-waiters; Z and O are ticket offices; I is the pantry; W is the stairway to the roof garden and supper room; C is a ladies' room; S is the restaurant.

Figure 10 is a plan of the ball room, or concert hall. Above the restaurant K K are lobbies; H is the hall; E, the stage; F, refreshment lobby; G, gentlemen's room; D, waiting lobby; C C, ladies' rooms.

Figure 9 is a horizontal section above the concert hall floor, showing the gallery in plan; room *l* is intended for a parlor or reception-room when the hall is used for a concert, and for a supper room when it is used as a ball-room.

(TO BE CONTINUED.)

FOUNDATIONS.

IN a paper on "Engineering Features of the Operating Department of Railroads," read a few months ago before the Illinois Society of Engineers and Surveyors, E. L. Morse said:

"On good solid ground the subject of preparation for foundation is not a difficult one. Where the soil is wet clay, soft and yielding, or marshy and inclined to quicksand, it becomes a question sometimes of going deep enough to get solid ground, or to devise some means of getting a solid bearing surface. This may often be accomplished by going below the base of foundation, and filling in with gravel, thoroughly tamped and pounded till quite solid. A better plan, I think, if the soil will remain wet, is to use plank under the masonry, making the foundation pit larger than the intended masonry, so as to give a larger bearing surface, first having the bottom of the pit thoroughly tamped before putting the plank in place.

"I lately had occasion to put plank under stone foundation piers for water tanks. The soil in these cases was wet clay, quite soft, and in rather low ground where it would not be likely to dry out. The piers were 4 feet in height, increased, in one case, to 6 feet to get a greater depth, 5 feet square at base, and supported a load of about twenty tons. The pit was made 6 feet square, and prepared, as described, by tamping, and pounding the earth down solid, then putting in two layers of 2 inch oak planks upon which the masonry was built. The same plan has been used under post foundations, and also under walls for buildings.

"Earth should be filled and tamped around all masonry, and in the case of walls that have an earth pressure on one side only should be filled and tamped first next the wall and then away from it to lessen the danger of overthrow from the earth pressure."

NATURAL AND ARTIFICIAL STONE COMPARED.

A WRITER in the London *Builder*, who is credited with having carefully studied the comparative merits of natural and artificial stone for the various purposes to which they are applied, states that for many of those purposes well-made artificial stone, composed of granite, sand and hydraulic lime, Portland cement or blue lias cement, mixed in due proportion and formed into flagstone, ashlar, steps, copings, window sills, and, indeed, all forms for which stone is used, molded or plain, is, beyond all comparison, the cheapest and best. Contrasted with ordinary flagstone, with its characteristic property of separating naturally in flakes or layers, artificial stone possesses the advantage of homogeneousness, that is, a substance all of one kind throughout. In some well-known cases bridges in parks have been constructed of Portland cement, beton coignet, the result proving how lasting such material can be made when proper care and knowledge are used in proportioning and mixing the materials. The fact is stated that, as a trial and test of comparative wear between natural Portland stone and artificial Portland cement stone, there were placed at a bank in London two doors, one each of these two materials, and the artificial stone door wore out three of the natural stone.

ELECTRIC POWER TRANSMISSION IN FRANCE.

AT a recent meeting of the Société des Ingénieurs Civils, M. Hillairet gave the following particulars of the electric transmission at Domène. The electric service which he established last year at the small town of Domène in Isère sets in motion the works of Chevrant. Domène is situated in the valley of Grésivandau on the left bank of the Isère, at the foot of the western slope of the mountain of Beldonne, which dominates the Dauphiné Alps. The railway line from Grenoble to Chambery serves this locality, and has contributed to the development of its industrial power for more than 20 years. The hamlet of Montier is situated at about 500 m. from Domène, surrounding the paper works of Chevrant, which supply the greater part of the neighboring population with work.

The increasing development of this factory, which had necessitated the establishment of auxiliary steam engines in aid of the primitive turbines which work under a fall of 50 horse-power, found itself obliged to modify its steam apparatus and to endeavor to utilize the power of a fresh fall; this would have been impracticable with steam engines on account of the expense of combustibles in this region, where most of the works owe their prosperity to the utilization of natural forces. The employment of electric transmission was decided upon, and two falls had to be examined with this view—one situated near the railway, and the other on the mountain falling from the turbulent stream which crosses the town of Domène lower down before discharging itself into the Isère. M. Hillairet rejected the first as better fitted to supply an ordinary factory on the spot, and chose the second. This rejection was opportune for a company to whom the fall was conceded some months later, and by whom it is now utilized. The latter fall is about 1 kilom. from the village of Revel; its lower level terminates at the hamlet of Eaux. At this point, 5 kiloms. from the Montier Mill, he has erected the factory of La Force, where the generating turbine and dynamo are installed, which transform the greater part of the hydraulic power now used into electric power. The water source is 700 m. above the factory of La Force, with which it is connected by a leaden pipe having a fall of 10 per cent., which gives a difference of level of 70 m. between the extremities. This turbine, with a horizontal axis, is attached directly to the generating dynamo, from whence start the two wires of the overhead line which unites this machine to the receptor of the Montier paper mill. This receptor acts directly on a groove pulley, over which ten wires of 0.050 m. run and communicate the power derived from La Force to the principal transmitter of the mill.

The principal records of this transmission are as follows: Generator: Maximum power, 300-horse; maximum speed, 240 revolutions per minute. Receptor: Maximum power, 200-horse; maximum speed, 300 revolutions per minute. Length of line 5 kiloms.; maximum electro-motive force, 2,850 volts; maximum current, 70 amperes. Resistances: Line, 3.474; generator, 0.950; field, 0.690; total resistance of the circuit, 6.829. Electric yield calculated according to the resistances, 83 per cent.; gross average mechanical yield, 63 per cent. The calculations of the mechanical yield have been made by substitution; the stopping of the turbine has been effected with a brake, which afterwards serves to test the power of the receptor.

---

*Part I.—General Description and Perspective, Front and Side Elevations, Longitudinal and Transverse Sections, and General Plan, and Plan of Roof Garden, was published August 30, 1890.

This transmission has been in use since the 1st of November, and from that time it has not ceased to work for a single instant, either during the winter or during the storms which have lately prevailed. The service has been continuous from the first moment, and no interruption has occurred since it was first established. The work of the factory has considerably increased with the increased power at its disposal. The results have been so satisfactory that La Force is likely to become a central station, distributing 2,000 horse-power in four different directions to a maximum distance of about 15 kiloms.

COST OF REPAIRS OF PILE BRIDGES.

In discussing the subject of cost of repairs of railroad pile bridges before the Illinois Society of Engineers and Surveyors, A. N. Talbot gave the following particulars:

On the Chicago, Burlington and Northern Railroad, 331 miles contain an average of 320 feet of pile and trestle bridges per mile—an unusually large amount. The cost of repairs per lineal foot, in 1888, was 23 cents. On the Western Division (in Colorado) of the Atchison, Topeka and Santa Fe Railroad, pile and trestle bridges with oak piles will last from ten to twelve years, and their renewal costs from $6 to $7 per foot.

Through the courtesy of Mr. W. H. Earl, Mr. Talbot was enabled to present the following summary of the cost of pile bridge repairs, excluding renewals, on the A. T. & S. F. R. R. in Central Kansas.

Cost of Pile Bridge Repairs for 1889.

Subdivision.	Miles.	Total feet of Bridges.	Feet per Mile.	Total Cost.		Cost per Foot.	
				Labor.	Material.	Lab.	Mat'l.
Main Line....	168	2,639	15.71	$593.62	$185.08	.225	.07
Branch Line..	99	6,655	67.22	361.92	127.73	054	.019
Branch Line..	30	3,225	107.50	28.77	......	.009	.....
Branch Line..	233	28,660	123.00	920 01	195.67	.03	.2006
Branch Line.	84	5,250	62.50	503.20	91.55	.096	.012
Branch Line..	156	10,180	65.26	754 19	164.16	.074	.915
Branch Line..	46	2,892	62.87	162.50	40.10	.050	.014
Totals. .	816	59,501	72.9	$3,324.31	$804.29	.056	.0135

The above does not include some repairs from wrecks and fire; supervision included except engineering; second-hand material largely used; estimated at $10 per M. In connection with this he says:

"Whenever a bridge needs extensive repairs I renew it using the old material elsewhere; none of the material is wasted; it is all worn out in one way or another. The best of it goes to repair other old bridges, then when they are renewed all the material is old together. Of course if we had no use for the material this plan would not be economical; but we are oftener short of second-hand bridge stuff than we have a surplus. We estimate the value generally at $10 per M. We renew our pile bridges when seven to ten years old, mostly from eight to nine years. Piles generally go first, and there are generally helpers alongside of piles by the time we renew. Sometimes where a bridge has a good top and not over 60 feet long we put in new piles and caps, then move the entire top to fit. Longer than 60 feet top has to be taken to pieces.

"I now require a systematic inspection of every bridge in all its parts as often as once in 30 days. The inspector enters in a book each bridge number, date and condition, noting in detail any defects; signs book at end of trip, sends it to the general foreman, who in turn sends it to me. I copy the notes and date of inspection in my office bridge books. I have two general foremen, and it takes a man under each about 20 days to get over the division. In addition, section foremen have track walkers examine bridges daily for broken stringers, that being the only thing liable to give out suddenly. We still have a good many stringers split from the shoulder; generally a bolt put through makes them all right again."

According to *Practical Electricity*, a storage battery street car was tried at Providence, R. I., recently, with good results. The car is described as being similar to those on Fourth Avenue, New York, and is very comfortable. Power is applied by two Thomson-Houston motors, and the car floor is one step above the platform. There are two iron folding gates at each end of the car. The car is lighted by 16-candle incandescent lamps, and weighs seven tons with all its appurtenances.

A telpher railroad is one of the interesting features of the exhibition recently held at Edinburgh, Scotland.

FALSE RUMOR ABOUT THE KINZUA VIADUCT.

REFERRING to the recently circulated newspaper item that the famous Kinzua Viaduct, on the line of the New York, Lake Erie and Western Railroad, was to be replaced by a heavier structure, Adolphus Bonzano has addressed the following letter to the New York *Tribune:*

SIR: The report having been widely circulated by the press that the great Kinzua Viaduct, on the line of the New York, Lake Erie and Western Railroad is to be removed on account of its not being strong enough, and that a new line is contemplated, I addressed the following letter to Mr. Charles W. Buchholz, the engineer of bridges and buildings for this company:

PHOENIXVILLE, PENN., September 4, 1890.

MY DEAR MR. BUCHHOLZ:

I heard that the Kinzua Viaduct was to be either abandoned or removed and a new line was contemplated to be built. I write to ask you whether this rumor is correct, and if so, would ask the reason why the viaduct is to be removed. Has the structure shown any signs of weakness in any part, such as loose rivets, or any excessive defection or lateral motion? All of which I doubt very much. Kindly let me hear from you at your earliest convenience.

I remain, yours very truly,
A. BONZANO.

To which Mr. Buchholz replied as follows:

NEW YORK, September 5, 1890.

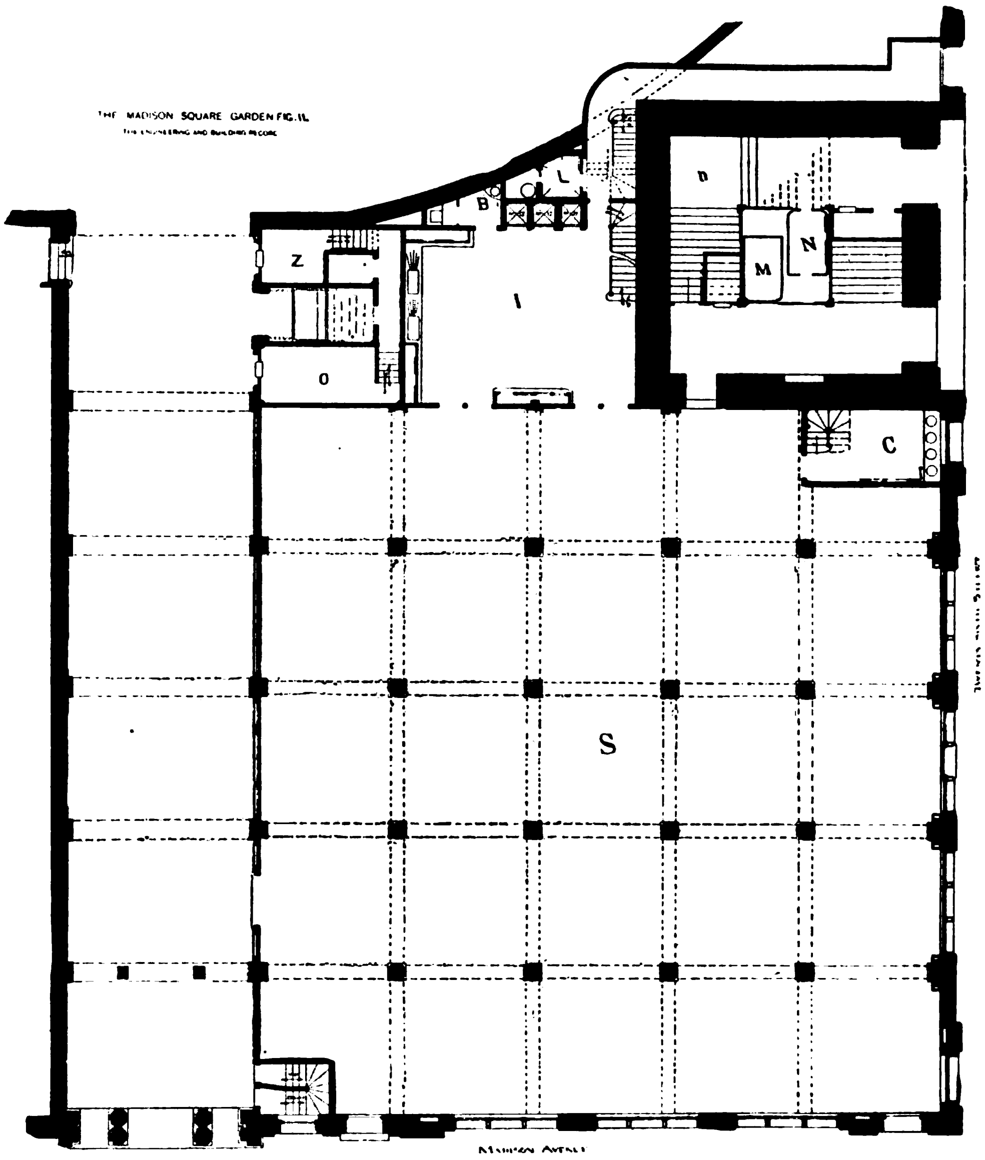
DEAR SIR: In answer to your favor of the 4th inst., I beg to say that the announcement that the Kinzua Viaduct is to be abandoned is a mere newspaper rumor. I heard nothing of it until last week, while I was in Chicago.

The structure has shown no signs of weakness of any kind, and maintains its full efficiency for the loads it was designed to carry.

Respectfully yours,
CHARLES W. BUCHHOLZ, Civil Engineer.

This viaduct is one of the most important railway structures in the world and is of recent construction, having been built in 1882. It is 2,052 feet long, 301 feet at its greatest height, and divided into groups of spans of 40 and 60 feet alternately. It is designed for carrying trains of coupled consolidation engines, each engine weighing 161,340 pounds on a wheel base of 45 feet 3 inches, and 88,000 pounds on a wheel base of 14 feet 9 inches. It is proportioned to resist a wind pressure of 50 pounds per square foot on the unloaded structure and 30 pounds per square foot on the loaded structure. Under the above loads no part of the structure is strained more than one-fifth of its ultimate strength. The viaduct is as safe and as strong as 90 per cent. of all the railroad bridges now in daily use.

ADOLPHUS BONZANO.
Vice-President and Chief Engineer.
Phoenixville, Penn., September 11, 1890.



THE MADISON SQUARE GARDEN FIG. 11.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

A LARGE PIPE CASTING.

THE CLARENDON WATER-WORKS COMPANY,
WILMINGTON, N. C., September 15, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: The item in THE ENGINEERING AND BUILDING RECORD of the 13th inst. headed "A Large Pipe Casting" must have been penned by one who was not posted. Pipe 48 inches in diameter has been used by a number of cities in the past 37 years. New York City used 60-inch pipe in 1861 and 72-inch in 1865, and Boston laid 60-inch in 1877. Hub and spigot pipes 96 inches in diameter were made by the Amoskeag Manufacturing Company, of Manchester, N. H., in 1873, and flanged pipes still greater in diameter are in common use for turbine wheel penstocks.

JOHN C. CHASE.

VITRIFIED PIPE FOR SEWERS.

NEW YORK, September 15, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: A quotation from a published address on the above subject matter contained in your issue of September 13 deprecates the use of the vitrified pipe for sewers of larger diameter than 15 inches. Since you ask for the experience of other engineers I would say that this conclusion is not borne out by my own experience and I regret to see such an opinion advanced unaccompanied by good reasons, because the sanitary advantages of smooth surfaced pipe over common brick, *cæteris paribus*, are certainly worth utilizing. Large pipes can be and are made strong enough to withstand heavy earth pressure; they can be and are burned so as to form, if not true circles, then ellipses with an eccentricity not exceeding one-half an inch. If the author of the above notes practices his former method of laying pipes *concentric* by a peculiar device, I think patented by him, his failure of making large pipes do for sewerage purposes may be explained. Sewer pipes should never be laid concentric, but so that the inside bottom forms an even surface, leaving the entire projection due to eccentricity entirely at the top where it is comparatively harmless. The larger pipes, when culled and measured, should be marked so that the larger axis in every pipe can be placed vertically instead of haphazard, and further diminish the projections at the joints. In pipes over 18 inches in diameter and not over 2 feet long, it is, moreover, quite feasible to smooth off the inside joint by pointing with cement, if this be considered desirable.

Regarding the use of but a 4-inch ring for brick sewers, 3 feet in diameter, your editorial comment is quite to the point. In hard ground a single ring suffices for this diameter. But ordinarily it is not good practice to go beyond 2½ feet. In New York, even in rock, two rings are used. In New England, in good ground, one ring is generally used up to 2½ feet. In Europe even smaller sewers are rarely built with less than two rings. In Philadelphia all the old branch sewers (3 feet in diameter) were built with a single ring and are reported to be generally out of true form. Many of them have here and there collapsed.

RUDOLPH HERING.

THE SUBWAY PROBLEM IN NEW YORK.

OSAWATOMIE, KAN., September 10, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: I have read your columns with deep interest in regard to the inconvenience to travel caused by tearing up the principal streets in your city to construct and repair sewers, water pipes, gas mains, telephone conduits, and all other pipes and their connections to the houses.

That these sewers, water, gas, electric and power mains and their connections must be constructed no one questions. To make a subway and all the connections necessary in Broadway would cost money and be an inconvenience.

Would it not be better to construct the subway referred to on page 193 of your publication between the streets in the alley, so as to supply the stores or houses with gas, water, telephone, power, heat, etc., without in any way disturbing the front streets? Where the elevation is suitable the sewer could be below and the pipe duct above. Light and air could be admitted from skylights, ventilating towers erected that could move all foul air and gas and prevent accident, thus doing away with mechanical ventilation. All connections can be made from rear of houses or stores with sewers, etc., etc., easier than in front.

Please excuse this presumption on my part from my humble station, but for 30 years I have watched this trouble continually increasing, and believe, with you, something must be done.

H. PARKER.

[Unfortunately for our correspondent's plan, New York has no alleyways in the rear of houses. Land is so valuable that practically the entire blocks are built over. In the case of tenement and apartment houses the law at one time permitted 90 per cent of the lot to be covered. The amendments to the Tenement Act of 1879 restricted covered space to from 65 to 78 per cent. at discretion of the Health Department. This is only for tenement or apartment houses. Business structures may, and usually do, cover the entire depth of the block. Blocks are 200 feet deep by 400 feet long, and streets 60 feet wide in residential portion of the city.]

BOOK NOTICES.

HANDY LISTS OF TECHNICAL LITERATURE. PART III. ENGINEERING AND MECHANICS. Compiled by H. E. Haferkorn and Paul Heise.

Any one who has had occasion to hunt, in the usual tedious manner, through scattered lists of reference books for any particular volume, will at once appreciate the convenience of the lists issued by Messrs. Heise and Haferkorn. Part III., which has just become available, is devoted to books on engineering and mechanics, and comprises over 2,100 works. The main entry of each work is found under the author's name, giving full title, year of issue, publisher's or agent's name, editions and price. The publisher or agent of each book is indicated by a system of abbreviations which are explained by an accompanying key. The subject headings are entered in the same alphabetical series as the authors, but are distinguished by being printed in italics. Considerable attention has been given to the preparation of cross references. A list of new books and editions, published in 1889 and 1890, makes the entries practically complete up to date. A separate list of newspapers, periodicals and annuals has also been furnished.

TRACING PAPER.

ACCORDING to *The Railroad Gazette* the Austrian hydrographic bureau adopts the following method of making paper transparent for copying drawings. The sheet of paper being placed over the drawing to be copied, it is lightly rubbed with a ball of cotton saturated with pure benzine. The tracing can then be readily made, owing to the resulting transparency, and the benzine, on evaporating, leaves the paper opaque as before, and without any trace of odor. Absolute purity of the benzine, however, must be insisted upon to secure good results.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department*. Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

CANDLE POWER OF ELECTRIC LIGHTS.

Samuel C. Lancaster, City Engineer, of Jackson, Tenn., writes: "Can you tell me how I may ascertain the actual duty, or candle-power, of a Brush electric light? There is a controversy between our city fathers and the manager of our electric lighting plant as to the candle-power furnished, their contract requiring 2,000 candle-power to the lamp, which, the city believes, they fail to furnish. How can we test this, and is there not some gauge made for the purpose?"

[The intensities of all lights are measured by comparison with the lighting power of standard sperm candles; hence the term candle-power. Probably the simplest form of apparatus, or photometer, for making the necessary measurements is that devised by Bunsen. It consists of a paper screen, on which is a grease spot, making that particular part translucent. The principle of the device may be briefly outlined as follows: If the paper be illuminated by a light placed in front, the spot appears darker than the surrounding space. If, on the contrary, it be illuminated from behind, the spot appears light on a dark ground. If the greased part and the rest appear unchanged, the intensity of illumination on both sides is the same. In applying the apparatus the standard light is placed on one side of the screen; the light to be tested is on the other side and is moved in a straight line to such a distance from the screen that there is no difference in brightness between the greased part and the rest of the screen. By then measuring the distances of the lights from the screen their relative illuminating powers can be determined, being respectively as the squares of their distances from the screen. Several other forms of photometer have been designed, such as Rumford's and Wheatstone's, but the one just described is probably most extensively used.

The standard sperm candle, of which there are six to the pound, burns 120 grains an hour, and is the light standard in this country and in England. Argand gas burners are sometimes used, as may be suggested by any particular case, in place of standard candles, having first, however, been compared with the standard candle, so as to obtain for them a definite measure of lighting power. The standard in France is the Carcel lamp, which equals 7.4 standard candles. The difficulty of getting carefully made candles to give a light sufficiently uniform for standard purposes has led, in some cases, to the adoption of special units consisting of lights formed by burning certain mixtures of gas and air, at certain rates of combustion, in specially constructed burners so as to produce flames of definite height. These have been found to answer well in practice.

As regards the actual lighting powers of any of the electric arc or incandescent lamps on the market it is no secret that they fall far below the commercial ratings. There seems to be a tacit understanding that a 2,000 candle-power arc lamp does not develop anything approaching the light of 2,000 standard candles, nor that the much-used 16 candle power incandescent lamps really equal 16 standard candles in illuminating power, and the same is true of all intermediate ratings. Just why it should be so is past finding out. As a matter of fact a so-called 2,000 candle-power arc lamp generally falls short of even 1,000 candles in lighting power, and 16 candle-power incandescent lamps rarely give a light of more than from 12 to 14 candles. The claim of the electric lighting plant manager at Jackson, that his 2,000 candle lights are 2,000 candle lights *actually* is certainly exceptional, and would probably not be substantiated by actual test.

In classifying lamps as regards lighting power it must also be borne in mind that the intensities vary at different angles. Experiments recently made in Germany to determine the candle-power of arc lamps showed that in a Siemens differential lamp, supplied with a current of 14 to 15 amperes at from 48 to 52 volts, the horizontal intensity was about 196 candles (German, very nearly the same as the English): it increased rapidly to about 20 degrees below the horizontal, where it was 1,150 candles, then more slowly until it reached a maximum at about 42 degrees below the horizontal plane, where the light was 2,014 candles; it then began to sink rapidly until below 60 degrees there was no light but only shadow. The average intensity was 1,228 candles, with the globes on; the actual light obtained ranged from 510 candles downward to 1,183 in a direction inclined 40 degrees below the horizontal, with an average illuminating power of 834 candles when freshly whitened reflectors were used.

The fact that electric light men themselves admit the shortcomings of the present system of lamp classification was very strikingly brought out at the recent Cape May, N. J., convention of the National Electric Light Association. Dr. Louis Bell, of New York, in there discussing the shortcomings of the adopted ratings, with special reference to incandescent lamps, added: "With the arc lamp we unfortunately know that the case is even worse. * * * We know only too well that the nominal candle powers of arc lamps are quite different from the real. The whole subject is in a tangle which at first seems almost hopeless. Heretofore it has not been specially important in the early stages of electric lighting, because people did not look so closely then into the exact conditions under which the light which they purchased shall be given; but as the electric lighting business comes more and more down to close competition and hard commercial lines it becomes more and more necessary to look after these things, and to define just what we mean by the lights which we contract to furnish, and to arrange some way by which there shall be general consent as to the meaning of the terms which we use."

Mr. Alexander, in speaking on the same subject, called to mind a measurement, made three or four years ago, by which it appeared that a 2,000 candle-power arc lamp varied from 134 to 1,386 candles, according to the measurements made then; but still they were all called 2,000 candle-power lamps. These and many other similar points brought out at the Cape May meeting would seem to show very conclusively that, in general, users of electric lights are paying for something which they do not receive.

In the case of our correspondent we can suggest only that the question might be settled satisfactorily to all concerned by having photometric tests made of the lamps in dispute by some electric expert. The average candle-power would be the result to be determined and on which, no doubt, the claims of the electric light company are based.]

HOW TO KILL GRASS AND WEEDS IN GUTTERS AND SIDEWALKS.

John W. Howard, City Engineer, Savannah, Ga., writes: "Will you, or some of your readers, inform me as to the best and most appropriate method for killing grass and weeds that grow up in our gutters and sidewalks, frequently forcing themselves up between the brick and stone? I am informed that some kind of chemical is being used, in some cities, for the purpose of destroying such grass and weeds. If this be the case, would you give me the name of the manufacturer?"

[We shall be pleased to hear from any one who has had experience in this matter. The question asked by our correspondent comes up for consideration every now and then, and is of interest in all places where light street traffic is apt to permit such growths of grass and weeds.]

MAKERS OF WROUGHT-IRON CEMENT-LINED PIPE.

Thomas J. Callahan, of Renovo, Pa., asks: "Could you give me address of parties that make wrought-iron cement-lined pipe?"

[On inquiry, we have been able to obtain the name of but one company making such pipe—viz., the New Haven Patent Water Pipe Company, of New Haven, Conn. We would be pleased, however, to hear from any of our readers who know of other makers.]

The Reading, Pa., Board of Health Committee on Epidemics has made an investigation into the prevalence of typhoid fever at East Reading, and reports that it is due to the use of water from springs and wells in the neighborhood.

DOMESTIC PLVMBING HEATING LIGHTING & VENTILATION ENGINEERING

DOMESTIC MOTORS.

The rapidly extending uses of power in the various branches of domestic engineering have stimulatd, in a remarkable degree, the design and construction of what have become popularly, and with some reason, known as domestic motors—a class of engines which require little, if any, skilled attendance, and are consequently well adapted to places where the care and attention necessary to the general type of steam engines are not available, or where the employment of special engine and boiler attendants would not be justified.

For the driving of ventilating fans, small pumps for the water supply of houses, laundry machinery, printing presses, and a variety of other apparatus which will readily suggest itself, these motors have deservedly come into favor and have shown themselves capable of doing excellent service, so much so, that their sale has gradually been extended to a large number of users of comparatively heavy power, such as small machine shops for example. Besides dispensing with skilled attendance, motors of this class have the obvious advantage over the ordinary steam boiler and engine plant, of usually involving expense for power only while power is actually being furnished. There is no delay and expense, as in the steam boiler, in getting up steam, nor is there, as in the case of the steam boiler again, a needless and consequently wasteful surplus of power after the actual demand for power has stopped. The expense begins and ends with the motion of the motor.

Ten or twelve years ago probably the only motor of this general type was the gas engine and, at the present time, it is still the most widely used. In many instances it has shown itself to be a formidable rival of the steam engine, successfully driving machinery for which, in its earlier days, it was considered not at all well adapted. To the original small sizes of fractional horse-power, and of one, two and five horse-power, have been added sizes rated at 10, 20, and even 50 horse-power—ample evidence of the growing popularity and fitness of the engine for heavy duty. The early forms of gas engines were all of the single cylinder class. The first noteworthy change in design, therefore, was naturally found in the adoption of two cylinders. The two-cylinder engines, in turn, were followed by quadruple engines, the larger number of cylinders being calculated to secure greater regularity in motion and higher efficiency, or, what amounts to the same thing, greater economy in the consumption of gas. For general work, however, the single cylinder engines have maintained their degree of favor, appealing to the larger class of small power users by their simplicity of construction and consequent immunity from derangement of delicate parts of mechanism. Gas engine builders, moreover, have not been unmindful of the fact that this simplicity of construction is of the first importance in any engine which is to suffer the abuse of untrained handling. Hence it is not surprising that, even in the later forms of gas engines, the multi-cylinder principle has received but limited application. The power of all engines of this class is derived from the explosion of mixtures of gas and air in various proportions.

Intimately related to the gas engine is the petroleum engine, or oil engine, as it is sometimes called. In this engine a mixture of air and petroleum, in the form of spray, is introduced into the cylinder and is fired by suitable igniting apparatus. Where a supply of gas is not available the engine offers important and readily apparent advantages. Its development has received special attention in England where a number of different designs are now on the market. One of its latest applications is found in the English lighthouse service for compressing air for operating foghorns, as noted in The Engineering and Building Record of September 13, 1890.

A similar duty is performed in both the English and the United States lighthouse service by hot-air engines, of which there are several well tried forms on the market. The principal use of the hot-air engine in this country, however, has been found in the pumping of water in buildings. The engine and pump are made in combined form and have been widely adopted, constituting a pumping outfit at once simple and economical. As a motor for general small power purposes, however, the hot-air engine has not found so much favor, its main drawback being that, compared with other motors of equal power, it is a large and cumbersome piece of machinery.

In the line of motors, which cannot be classed as heat engines, we find the various makes of water motors. Progress with these has been rapid during the past few years, and the prospective user will find a number of designs from which to choose. In some localities, where comparatively high water pressures are maintained in the supply systems, water motors have come into extensive use to the exclusion of many small engines of other types. The entire absence of danger in their operation, ease of management, and general cleanliness have tended largely to make them popular.

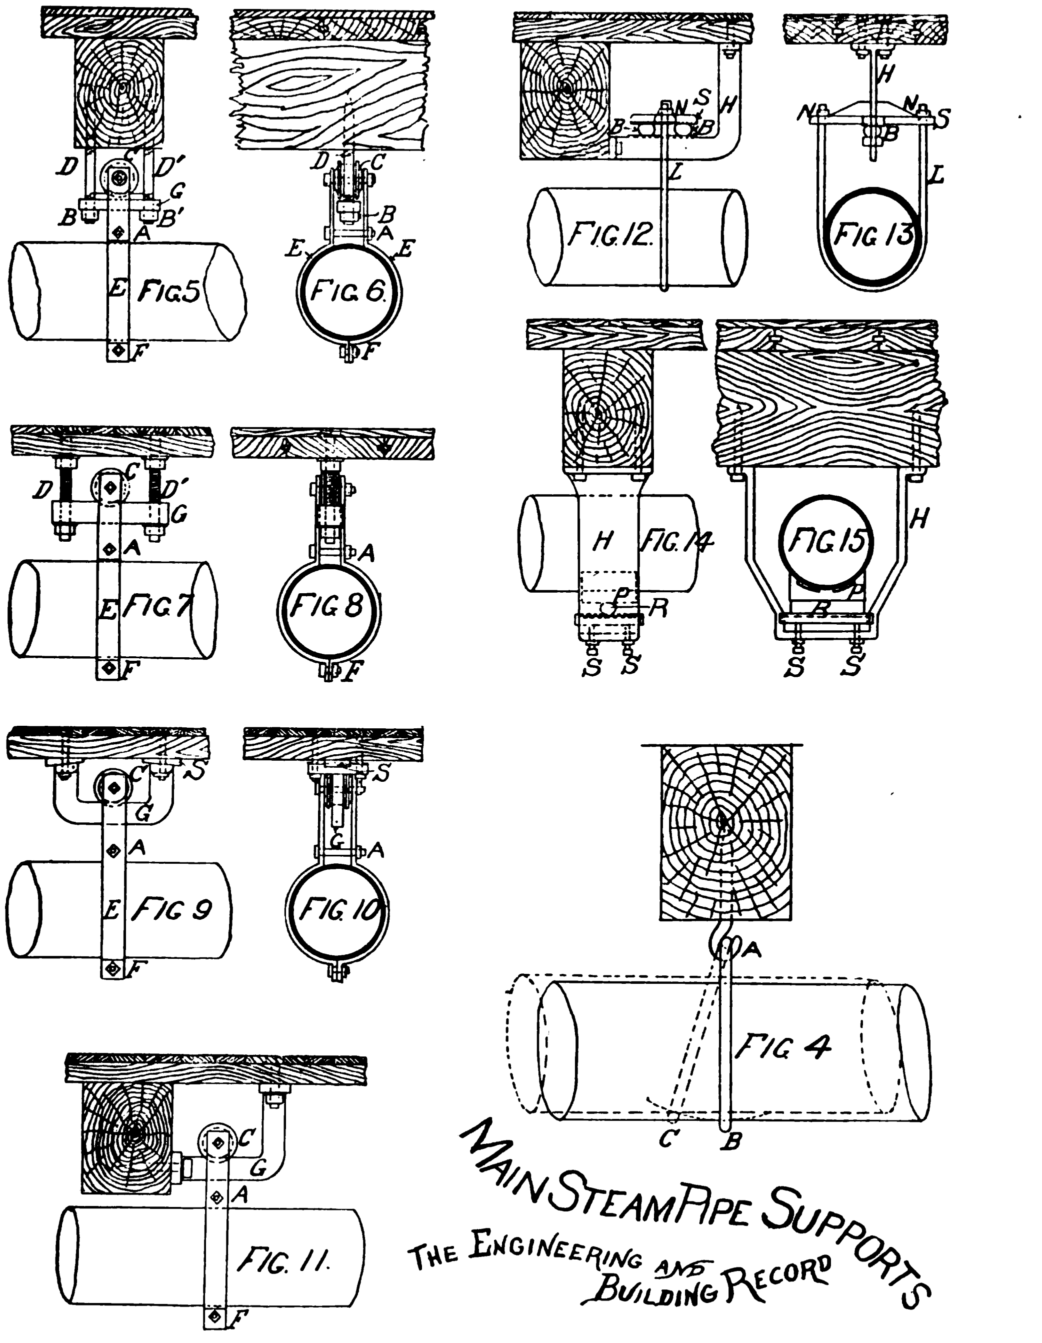
It is but proper that in this brief review we should direct attention also to several special forms of small steam engine and boiler outfits, which it has been endeavored to present in a shape likely to appeal to the unskilled user. The outfits are made principally in sizes of one and two horse-power. The boilers are heated by kerosene, and the working of both boilers and engines is entirely automatic and under perfect control. The oil fuel is used in the form of spray, produced by steam-jet atomizers, and the regulation of the fires, steam pressure and water level in the boiler is effected without any dependence being placed on a possible attendant. Danger from carelessness or ignorance is thus practically eliminated.

The latest arrival among small engines for household and other uses is the electric motor, and its special fitness for a wide range of application is at once apparent. The motor is well beyond the experimental stage, and is now put on the market by over a dozen firms in the United States. In capacity it is now made to range from small fractions of a horse-power up to relatively large sizes, so as to meet the requirements of the constantly increasing number of users. Some of the very small sizes, designed specially for such light work as running sewing machines, jewelers' and dentists' lathes and drills, etc., have been arranged to work with battery currents, and the outfits would seem to offer every possible convenience and to successfully meet every requirement for satisfactory work.

MAIN STEAM-PIPE SUPPORTS.

THE second of the series of articles on steam-pipes and their connections, published in the August number of *The Locomotive*, and already referred to in our last issue, is devoted to the support of main steam-pipes.

These are often hung up in a slipshod and inefficient manner, no proper allowance being made for the movement of the pipe by expansion. As a consequence, joints are strained and become leaky, flanges are broken off, and in many instances the hangers are pulled out and the whole line, or a portion of it tumbles down bodily. The usual support for steam-pipes is shown in Fig. 4. It consists simply of a ring or loop, which is slipped over the end of the pipe and supported by a gimlet pointed hook which is screwed into a beam above and admits of no adjustment. If the pipe is of any considerable length, the ring, when steam is turned on, assumes the position shown by the dotted lines in the cut.



MAIN STEAM PIPE SUPPORTS

THE ENGINEERING AND BUILDING RECORD

The pipe is raised, severe strains are thrown on the joints, and, unless a section is left uncovered where the hanger comes, the covering is badly torn. Few realize the severity of the strain set up in a long line of large pipe by using a hanger of this kind. In many cases the ring will be found lifted clear out of its supporting hook. Of course it is evident that when this is the case those hangers which do remain in place have to carry a greatly increased load, so that unless they are of excessive strength they are apt to give way. When one breaks the shock throws a severe strain on the next one, and if that gives out the whole line of pipe is pretty sure to come down.

Pipe of any considerable size should always be supported by some sort of hanger that will admit of a parallel motion when the pipe expands. Figure 5 is a side view and Fig. 6 an end view of one of the cheapest and best forms of hanger where the motion of the pipe is not very great. Two clips are made of 3x½ inch flat iron bent around to fit the pipe, so that when the nuts on the bolts at A and F are screwed up the pipe is tightly gripped. The upper ends of the clips are not brought together, but are left a few inches apart, and of sufficient length to allow the roll C to be placed between them as shown. The bolt passing through the clips and roll forms a bearing for the roll, which is grooved on its periphery, and runs on the bar G, which in turn is supported by the lag bolts screwed into the beam, as shown. The pipe may be raised or lowered by simply turning the nuts on the bolts, and may be set at any desired height.

Figures 7 and 8 show a hanger exactly similar in principle to the one just described, but available in a case where it would be necessary to carry a pipe as close as possible to the timbers. In this case the weight of pipe would be carried by the floor planks instead of the beams. With mill floors as constructed at the present time this would form a good support, especially if it were placed close beside a beam. Two bolts are let through the floor, the heads being flush with its upper surface so as to offer no obstruction. The bolts should be a "driving fit" through the planking, and have their threads cut of such a length that a nut and washer may be screwed up to the under side of the plank. The pipe is suspended from these bolts by means of bar, roll, and clips exactly as in Figs. 5 and 6, and the same facility of adjustment in a vertical direction is obtained as in that design.

Figures 9 and 10 show another form of hanger, in which the vertical adjustment is obtained by "shimming" with the wedges shown at S S, the remaining part of the design being similar to those already described. The objection to this form is that the vibration and shrinkage of the floor is apt to loosen the wedges so that frequent adjustment becomes necessary. This form might be used in some places with satisfaction, but we should not recommend it in preference to the ones described above.

Figure 11 shows another kind, in which no provision is made for adjustment vertically. When a line of pipe is run close to a wall so that there is no chance for the timbers or floor to settle appreciably, and so throw the pipe out of line, this form will answer every purpose if carefully put up in the first place.

Figures 12 and 13 show a different form of clip from those previously described. This is simply a bar of round iron bent around to fit the pipe and with threads cut on the ends. The ends of this clip pass through holes in the plate S, and are provided with nuts which enable one to make adjustment in a vertical direction. The plate S rests on two cast-iron balls B B, which roll with scarcely any friction as the pipe expands.

Figures 14 and 15 show a hanger made on a different principle, and which does not interfere with the pipe covering. A cast-iron saddle P, carries the pipe and rests on a cylindrical roller R, which gives the required freedom of motion endwise to allow for expansion. The friction in this construction is also very slight. The plate on which the roller R rests is supported by four set screws S S S S, by means of which the vertical adjustment is obtained, and the whole is supported by the casting H, which is securely bolted to the beam overhead.

CAREFUL ROAD MAKING.

THE Thomaston, Me., *Herald*, of recent date, says: "It is nothing unusual for a man to pay his tax by work on the roads, but the way Mr. Edwin McIntyre of Warren works out his tax is a little out of the common course. Mr. McIntyre goes over the piece of road he cares for at regular intervals and picks up every rock. He collects them in a wheelbarrow, takes them home, pulverizes them on a stone anvil and dumps them back into the road again. This practice he has kept up for 13 years. During that time he has ground and put into the road 15 cords of rocks. Mr. McIntyre not only measures them, but the last two years he has counted them. He found by actual count that in 1889 he used in this way just 67,604 cobblestones. It is needless to remark that this is one of the best pieces of road in the town."

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

STAYING A TANK.

"J. W. C.," London, England, writes: "An interesting case, showing the results of water pressure on the sides of a cistern, has recently come under notice. The cistern was of the shape shown in the annexed sketch, and about 10 feet square and 8 feet deep. Being fixed in a turret, the base of which the cistern filled, it was necessary to cut out a corner 2'6"x2'6", for access to the cistern from the bottom. The cistern was made out of $\frac{3}{16}$-inch wrought-iron plate, riveted to angle irons. There were several ¾-inch stay rods *across* the cistern to keep the sides from bulging outwards. The whole was galvanized. On filling the cistern with water the angle iron at X cracked, and the cistern became slightly distorted. There is little doubt that if stay rods had been fixed, to tie the angles A and B, this would not have occurred. But rods across this part would have been an obstruction across the access to cistern. I should like to know what you consider the best way of staying a cistern or tank of this kind, the size of rods, and where they should be placed?"

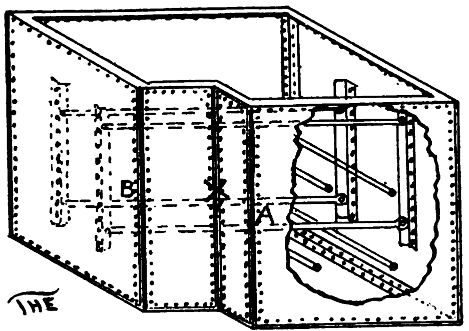


FIG 1.

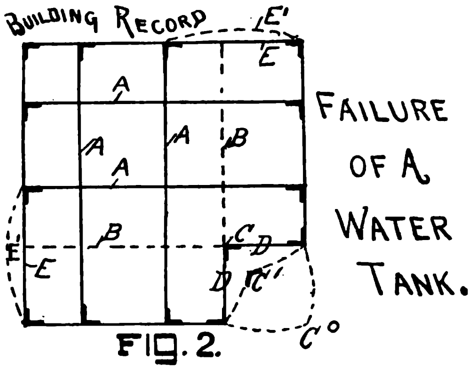

FIG. 2.

[From the above letter and sketch it appears that the cistern was stayed by two sets of rods, about in the position A A, etc., shown in Fig. 2. These were probably sufficient for the shorter two of the main walls, but left long unsupported lengths of wall at E and E, and weak places at D D, where the failure occurred. The water pressure would tend to bulge out walls E E to E' E', and cause the walls D D to move out till their intersection C reached C°. Of course they could not reach this extreme position without entirely destroying the angle X, Fig. 1, and they probably assumed a position like C'. An additional set of rods, B B, would have prevented any displacement of C and prevented distortion of D D and bulging of E E. One-half-inch rods would be ample to resist the strains.]

FIRE EXTINGUISHERS.

REFERRING to fire extinguishers, *Uhland's Wochenschrift* says that the theory of all such preparations is to cut off any burning object from the surrounding atmosphere. It is immaterial whether this be accomplished by a liquid or a solid substance. Water is the simplest and most natural one. Its efficiency as a fire extinguisher may, however, be increased by an addition of pulverized, common alum in sufficient quantity to obtain a saturated solution. On evaporating, this solution will leave on the material over which it was thrown a thin coating having a high resisting power to heat. Potash and common salt are not recommended, as the salts will volatilize and afterwards precipitate themselves in various parts of a room or building and tend to produce dampness, owing to their affinity for moisture.

ANNUAL REPORTS.

REPORT OF THE TRUSTEES OF THE SANITARY IMPROVEMENT BONDS OF THE CITY OF JACKSONVILLE, FLA., TO THE CITY COUNCIL. July 1, 1889, to July 1, 1890. With Report of Superintendent and Tables Annexed.

The report shows a small advance in the receipt of water rates over those of the preceding year. This, it is thought, would have been considerably increased, had provision been made for a stand-pipe which has been urgently recommended for several years. As it is, some large elevators had to be shut off, and the applications of several others had to be declined because this necessary supplement to the safety of the pumping machinery had not been supplied. R. N. Ellis, water-works superintendent, in his report, again urges the erection of a stand-pipe. There are now in use a little over nine miles of mains, and about two and a-half miles of temporary mains that should be replaced with cast-iron pipe of proper diameter. Three hundred and ninety-one water meters are in use. E. J. Howard, engineer at the works, reviews the present condition of, and the work performed during the year ended June 30, 1890, by the pumping plant. An appendix gives detailed tables of receipts and expenditures for the year.

THIRD ANNUAL REPORT OF THE CITY SURVEYOR AND SUPERVISOR OF STREETS AND HIGHWAYS, CAMDEN, N. J.; for the year ending March 1, 1890.

This is the third annual report, and is accompanied by tables showing the amount of work done and its cost, a list of all paved streets in the city, location of sewers, size, material, etc. There are in all seven of these tables. Table I. shows the streets paved, number of yards of paving done, number of feet of curb, gutter, etc., laid, number of yards of repairing, with cost of each, as laid during the year. Table II. shows the summary of the different kinds of paving done during the year, with the cost of each. Table III. shows the total number of yards of the different kinds of paving laid in the various wards to date, with the price per yard, year in which the work was done, and name of contractor. Table IV. shows the general summary of all paving now laid in the city, including the paving laid by private contract.

The total number of square yards of paving done during the year was 27,257 square yards, or equal to a street 25 feet between curbs of $1\frac{85}{100}$ miles in length, at an average cost of $1.58 per square yard, the total length of streets equal in width to 25 feet between curbs being $34\frac{44}{100}$ miles.

Table V., which gives location, size and cost of each sewer built during the past year. Table VI. shows the summary of sewer work during the past year, with total cost. Table VII. shows a complete list of all sewers laid in the city to date, together with the location, size, number of manholes, inlets, cost of each, when and by whom built.

There has been constructed during the year 5.527 feet, or $1\frac{4}{100}$ miles of sewers, at an average cost of $1.79 per foot, making the total length of sewers laid to date in the city 32 and $43\frac{1}{100}$ miles.

The department for several years past awarded contracts for repairs of sewer breaks, which proved unsatisfactory, owing to the unworkmanlike manner in which it was done, and the delay in doing it. For the past year it has had a corps of men especially for this purpose, this corps not only mending the breaks, but setting inlets and making connections to the sewers, and ready, at a moment's notice, to go to work either day or night. L. E. Farnham is the City Surveyor, and John Blowe, the Supervisor of Streets and Highways.

TRADE PUBLICATIONS.

STEAM AND HOT-WATER HEATING.

THE Western Engine Company, of Painted Post, N. Y., has sent out a new catalogue, devoted more particularly to steam and hot-water heating and to the Bronson water-tube boiler made by them. The boiler is described and illustrated in detail, and tables of dimensions and prices are given.

A COPY of the prospectus of the Young Men's Institute of the Young Men's Christian Association, of New York, has just been received. In the outline of the educational advantages which it affords attention is, among other things, directed to the classes of mechanical and free-hand drawing, carriage building and steam engineering.

SEATTLE and Tacoma, 42 miles apart, are to be connected by an electric railroad. This will probably be the longest electric road in existence.

Novelties.

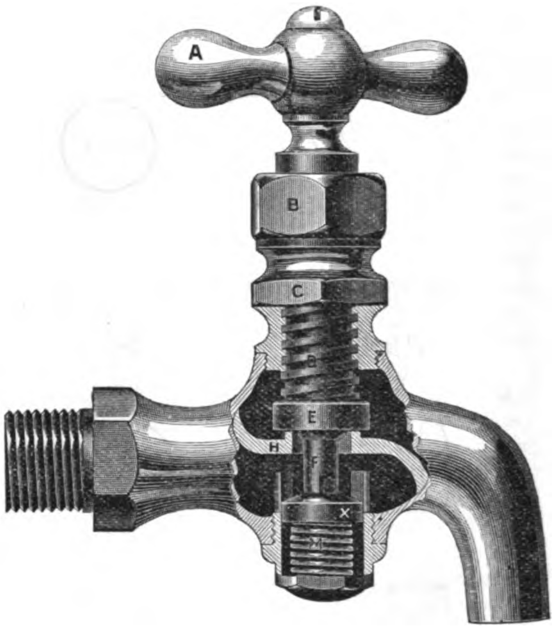
Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply indorsement.

THE "AUTOMATIC" COMPRESSION FAUCET.

THE H. A. Williams Manufacturing Company, 22 Milk Street, Boston, Mass., has just brought out the automatic shut-off faucet shown in the annexed cut. The latter represents the faucet closed to the passage of water, the valve E being seated on H. As the handle A is turned to open the faucet the valve E rises from its seat, as does also the auxiliary or shut-off valve X; one revolution of the handle A opens the faucet to its fullest extent and in this position the valve X is said to be just far enough away from the lower face of H to allow a free waterway through the faucet. If now a wrench is applied to the nut C the valve E rises still further, and the valve X, being actuated by the water pressure and the spring M, also rises until it meets the lower face of H and thus shuts off the water. This occurs before the nut C has been entirely removed, thus avoiding all splatter of the water; the washer may then be removed by unscrewing the tit F.



An additional advantage claimed for the faucet lies in the fact that when the valve E is wide open, its upper face makes a water-tight joint on the lower face of the nut C, and thus prevents any water getting up around the stem. The faucet should be opened wide before the nut C is removed.

ALLOYS FOR ELECTRIC FUSES.

THE following proportions for fusible alloys may be of interest to those who have occasion to make or use fuses in electric wire systems. They were given in a recent issue of *The Electric World*, and have been used in actual practice. The range of melting point is so great that almost any desired current can be probably taken care of without the use of too small a wire.

Lead.	Tin.	Bismuth.	Melting points, in degrees. Centigrade.
1	1	4	93 8
5	3	8	94 4
2	3	5	94.4
1	4	5	118.8
1	4	1	125
1	1	1	241.1
1	2	1	167 7
1	3	1	167.7
1	3	1	200

THE Mayor of the city of New York has been requested to appoint a citizen's committee to consider the plan of improving the westerly river side. One feature of the plan is to build a sea wall, or bulkhead, from Seventy-second to Ninety-eighth Street. The land under water is to be reclaimed, and for the entire length an avenue for general purposes is to be built.

THE MAINTENANCE AND OPERATION OF WATER-WORKS BY PRIVATE COMPANIES.

(Continued from page 212.)

7. INVOICE BOOK. 360 pages (4 quires). Horizontal ruling 3 to the inch. Record No. 930.

This is "journal ruled," with one extra vertical ruling following the date column for number of the voucher due to its place in Invoice Book, which should pertain to the bill in its entries in cash book.

There should be an index in which all bills should be alphabetically entered by seller's name, and referred to by "No. of voucher," instead of page.

The "pay roll" should be made out in bill form, as also a weekly summary of petty cash items, not loading up either Cash or Invoice Book with sums too small for bills. A "petty cash" book should be used, in which should be entered every individual item, and the account to which chargeable, and on Invoice Book simply enter the weekly aggregate of amount chargeable to each account.

All bills should be footed, and this footing should be entered in the last set of columns.

All bills, whenever approved for payment, should be copied on the Invoice Book, so that that book will show a full account of all expenditures incurred.

In case of transfers of charges from one account to another, they should be made through the Journal.

8. CASH BOOK. 360 pages (4 quires). Horizontal ruling 3 to the inch. Record No. 931.

Charge all sums received, noting account to be credited.

Credit all sums paid out, on vouchers only, noting account to be charged, and entering number of voucher opposite each item into which each bill may be divided.

On the last day of each month the receipts and disbursements on account of each ledger account for the previous month should be separately posted on the ledger cash, and on the opposite side of each of such ledger accounts.

9. JOURNAL. 270 pages (3 quires). Horizontal ruling 3 to the inch. Record No. 932.

To be used as a journal, for all cross entries, transfers, etc.

On the first day of each month, ledger accounts 6 to 17 inclusive should be journalized from footings of "Accounts Receivable Book," and properly posted to Ledger. Other accounts, cross entries, transfers, etc., should be journalized and posted to Journal whenever necessary.

10. LEDGER. 360 pages (4 quires). Horizontal ruling 4 to the inch. Record No. 933.

Contains no individual accounts except treasurer.

The ledger accounts to be kept are as follows:

No. of Acct.	Name of Acct.	No. of Acct.	Name of Acct.
1	Capital Stock.	26	Conduits, Force or Gravity Mains.
2	Bonds.		
3	Bills Payable.	27	Distribution.
4	Cash.	28	Buildings.
5	Treasurer.	29	Foundations.
6	Public Hydrant Rental Accounts Receivable.	30	Water-wheels.
		31	Boilers.
7	Private Hydrant Rental Accounts Receivable.	32	Pumps, either Steam or Power.
8	Water Accounts Receivable.	33	Fuel.
9	Meter Rents Accounts Receivable.	34	Oil and Waste.
		35	Lighting.
10	Services and Repairs Accounts Receivable and Payable.	36	Stand-pipe.
		37	Distributing Reservoir.
		38	Meters.
11	Miscellaneous Accounts Receivable.	39	Salaries.
		40	Legal Expenses.
12	Public Hydrant Rental.	41	Superintendent.
13	Private Hydrant Rental.	42	Engineering.
14	Water Rates.	43	Engine and Firemen.
15	Meter Rents.	44	Office Expense.
16	Services and Repairs.	45	Livery.
17	Miscellaneous Accounts.	46	Interest.
18	Bills Receivable.	47	Discount and Commission.
19	Organization.	48	Taxes.
20	Construction.	49	Insurance.
21	Real Estate.	50	General Expense.
22	Water Supply.	51	Dividends.
23	Improvement of Water.	52	Profit and Loss.
24	Storage.	53	Balance.
25	Water Power.		

1. *Capital Stock.*—Credit this account, and charge "cash" with the par value of all stock issued. Credit proper account, and charge "discount and commission" with all discounts on capital stock, or commission and expenses paid for the sale of the same.

2. *Bonds.*—Credit this account with the face value of all bonds, and charge the account for which the bonds were issued, whether "cash," "bills payable," "construction," or other accounts. Amount received for accrued interest will appear in interest account.

Credit proper account, and charge "discount and commission" with all discounts on bonds or commissions and expenses paid for the sale of the same.

3. *Bills Payable.*—Credit this account, and charge "cash" with all sums received from notes of the company.

Credit the full face of the note. When the note is paid, charge this account and credit "cash." If the notes read "with interest," then charge "interest," and credit "cash" with the amount of the interest, when the same is paid.

4. *Cash.*—Charge this account with all sums received. At the same time credit the account which may have furnished the funds.

Credit "cash," and charge proper account with all sums paid. If any bills are paid by treasurer, he must notify the principal office of number of voucher, amount, and date of payment, so that the treasurer may be credited and "cash" charged with the same, and "cash" credited and the proper account charged.

5. *Treasurer.*—Credit treasurer, and charge "cash" with all sums received from him. Sums received from the sale of material will not enter into the treasurer's account, unless the moneys are actually paid over to him.

6. *Public Hydrant Rental Accounts Receivable.*—Credit this account, and charge "public hydrant rental" with gross amount of all bills made out for public hydrants.

If any rebates are made before the bills are paid, charge this account, and credit "public hydrant rental." If rebates are made after the bills are paid, and the rebate is a cash transaction, credit "cash" and charge "public hydrant rental accounts receivable," take a receipt for the money paid, enter it in the invoice book, treating it as any other bill paid.

If errors are made in the amount of these bills, correct them by journalizing and posting as cross entries between this account and "public hydrant rental."

7. *Private Hydrant Rental Accounts Receivable.*—Credit this account, and charge "private hydrant rental" with gross amount of all bills made out for private fire protection.

Treat rebates, errors, etc., the same as detailed in account No. 6.

8. *Water Accounts Receivable.*—Credit this account, and charge "water rates" with the gross amount of all bills for "water rates," both "fixture" and "meter rates."

Treat rebates, errors, etc., the same as detailed in account No. 6.

9. *Meter Rents Accounts Receivable.*—Credit this account, and charge "meter rents" with the gross amount of all bills for "meter rents." This does not include anything charged for the sale of meters, or for setting or repairing meters, all of which go to other accounts.

Treat rebates, errors, etc., the same as detailed in account No. 6.

In closing this account at the end of the year, close it into "meters," and close that into "balance."

10. *Services and Repairs Accounts Receivable and Payable.*—Credit this account, and charge "services and repairs" with the gross amount of all bills for tapping the mains, furnishing and putting in service pipes, fittings, sidewalk stops, plumbing, etc., and the maintenance and repair of the same.

Credit "cash," and charge this account with all sums paid for labor, material, or expense in connection with the above.

Treat rebates, errors, etc., the same as detailed in account No. 6.

11. *Miscellaneous Accounts Receivable.*—Credit this account, and charge "miscellaneous accounts" with the gross amount of all bills made out for any purpose not already specified.

In case the bill is for the sale of material or the performance of labor belonging to any itemized department, then the account of that department should be credited instead of this account, but "miscellaneous accounts" should be charged with the amount.

Treat rebates, errors, etc., the same as detailed in account No. 6.

(TO BE CONTINUED.)

ARCHITECTURAL COMPETITIONS.

SAGINAW, MICH.—City Hall.—Plans are wanted until October 20, for the construction of a city hall building at this place. Estimated cost, $110,000. For circular of instructions, address John C. Matthews, City Clerk, as above.

WATER.

For Additional Water Items see Proposal Columns.

BLAINE, WASH.—It is estimated the system of water-works projected for this place will cost about $170,000.

MONETT, MO.—The sum of $14,400 has been voted by the people of this place for the purpose of establishing a system of water-works. Address the Town Clerk, for details.

LOUISVILLE, KY.—The Domestic Water-Works Company of this city wants machinery for its plant, including pumps, pipes, tanks, etc.

STEELTON, PA.—Estimates made put the cost of water-works for this place at $100,000. It is probable that operations will soon commence.

PULLMAN, WASH.—It is proposed to expend the sum of $8,000 on a water-works system for this place.

ST. LOUIS, MO.—Proposals for constructing the basins for the new water-works at this place will soon be advertised for, estimated to cost about $700,000. Bids for pumps amounting to $300,000 will also be wanted.

RITZVILLE, WASH.—Water-works for this place are now about a certainty.

HEBRON, NEB.—The water-works question at this place still remains undecided.

LEWISTON, IDAHO.—The capital stock of the Lewiston Water and Light Company has been increased to $100,000. Construction work will be proceeded with next spring.

CRESTON, IA.—It is estimated that the projected system of water-works for this city will cost the sum of $30,000.

SHEFFIELD, ALA.—Messrs. Johnson & Flood, hydraulic engineers, have been engaged by the City Council of this place to make the preliminary surveys for a system of water-works to be established at this place.

MONMOUTH, ILL.—Bonds in the sum of $15,000, at 5 per cent. are to be issued at this place for the purpose of establishing the projected system of water-works.

HUNTINGTON, L. I.—It is probable that the projected water-works system for this place will soon be established. For particulars address Joseph Irwin, as above.

YORK, NEB.—Reports say that the York Water-Works System has been sold to T A Post, of St. Louis, Mo., who obtained a judgment for $921.50 on interest for coupons. The sale was made on execution.

BROOKLYN, N. Y.—The scarcity of water in the 17th Ward, Greenpoint, will soon be relieved, for City Works Commissioner Adams September 15 awarded a contract for building a new water main to Harris & Maguire, at $12,000.

NEWARK, N. J.—The New York *Times*, of September 15, prints the following: "It is reported in Newark that the East Jersey Water Company has purchased a large tract of land from John Krean, of Elizabeth, in Upper Longwood Valley, near the sources of the Rockaway River. It is believed by those best informed on the question, that the East Jersey Water Company is making arrangements for using the Rockaway River as a source of water supply for some other city than Newark."

TALLADEGA, ALA.—The Talladega Gas Light and Water Company is about to increase its capital stock for the purpose of making improvements.

ROME, GA.—The East Rome Water-Works Company has, it is stated, received a contract to supply the city with water.

DARLINGTON, S. C.—The Darlington Water-Works Company has decided to establish a plant here, to cost $20,000. C. S. McCullough can furnish particulars.

ROANOKE, VA.—The local water-works system is to be increased.

SORRENTO, ME.—Preparations are being made for establishing a system of water-works at this place.

Contracting News Department.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

WATER.

(For additional Water Items, see preceding page.)

For works for which proposals are requested see also the "Proposal Columns,' pages i-ii-255.

Aurora, Neb.—City Clerk H. E. Metzger writes: "On August 26, we voted $7,000 more water bonds. The same will be used in purchasing another boiler, sinking the third well and extending the water mains."

Wenham, Mass.—Town Clerk Wellington Pool writes: "A petition is in circulation for the purpose of securing (in connection with other towns) an aqueduct supply of water for this town. The town to incur no liabilities—except for hydrants for use in extinguishing fires."

Madison, Ga.—City Clerk T. B. Baldwin writes: "The city of Madison some time ago advertised for bids for water-works, proposing to grant franchises, etc., to any company that would undertake to establish water-works. Since then we have done nothing towards the matter, as we did not receive any bids satisfactory to the city authorities."

Lebanon, Ill.—C. L. Robinson, City Clerk, writes: "We contemplate building water-works, the Holly system, but, as yet, no contracts are let. The committee is at work but has not reported any definite action to the Council; are now investigating in regard to obtaining water. As soon as that point is reached, the remainder will be consummated."

Santa Ana, Cal.—City Clerk Edward Tedford writes: "As soon as we sell the bonds we will be ready to accept bids for material and the work of putting in water-works."

Earlville, Ill.—Regarding the water-works project at this place City Clerk H. A. Chase writes: "Our council has had several meetings, to discuss the matter, and at their last meeting the matter was referred to the Committee on Fire and Water, with instructions to fully investigate different plans and prices and report to council for their action."

Lancaster, Pa.—Among the proposed improvements to the local water-works system at this place is a new 40,000,000 gallon reservoir, a new dam at Ranck's Mill, and pipe extensions. For particulars address Mayor Clerk, as above.

Mount Sterling, Ky.—The people of this place having voted to establish water-works it is probable that the construction of the plant will soon be commenced.

Eustis, Fla.—It is probable that important steps will soon be taken towards establishing the water-works system projected for this place.

Greenville, S. C.—The Paris Mountain Water Company has been incorporated for the purpose of establishing a system at this place. Address William S. Perot for particulars.

Chillicothe, O.—This city is taking preliminary steps towards establishing a water supply of its own, as the contract with the private company now holding the franchise is about to expire. Address C. A. Malone for particulars.

Atkinson, Neb.—The contract between the city of Atkinson and Meals & Godfrey for the placing of a water-works plant at this place was signed September 10, and work will proceed at once. The works are to be completed by January 1, 1891.

Morristown, Tenn.—Edward D. Bolton, of No. 44 Broadway, New York, has been engaged to make plans for a system of water-works here, and the construction will be commenced at once.

Burlington, Col.—Town Clerk J. W. Clement writes: "We as yet have taken no definite steps towards establishing a system of water-works at this place further than to appoint a committee to investigate the advisability of sinking an artesian well."

Lowell, Mass.—The Aldermen have passed the ordinance favoring a loan of $60,000 for purchasing a new engine at the pumping station. Mayor Palmer can furnish particulars.

Lynn, Mass.—The City Treasurer has been authorized to borrow $75,000 for the extension of the water-works plant.

Kalkaska, Mich.—A dispatch to the Grand Rapids *Democrat* explains the water-works situation at this place as follows: "A system of water-works is needed for fire protection and to furnish sufficient water in times of drought for lawns and gardens. The Village Council have had experts on the ground looking it over with a view to putting in water-works, but it is not yet settled whether water will be furnished us by a water company under contract, or whether the works when built will be operated by the village. It is proposed to put in a system of water mains, with hydrants and suitable pipes for supplying houses with water in all the principal streets of the village. The supply of water will be obtained from the Boardman River, which flows conveniently near, or from a large well with supply pipes, and will be pumped into and forced through these water mains and pipes by steam power. The estimated cost of this improvement is from $16,000 to $25,000. The people voted for it by a good majority, and as soon as our bonds can be floated, a contract will be made and work commenced on the job." This is confirmed in a letter from C. M. Phelps, City Clerk.

Quincy, Ill.—There is some talk of building a new water-works plant here. The Mayor can give information.

Madison, Fla.—J. Arthur Durst, of this place, writes: "The supply for the proposed water-works was decided to be most practical from subterranean sources, and the contract for the artesian well was awarded to me. The incidental difficulties of drilling in this region makes progress rather slow—the rock being hard. The distributing system will probably not be considered until the well is completed and tested for capacity and quality."

Arkadelphia, Ark.—Town Clerk T R Zimmerman writes: "The indications are that water-works, electric lighting and ice factory will be constructed at once. A committee of citizens will go to Camden in a few days to examine the works at that place. Communications in reference to water-works or electric light should be addressed to Geo. M Carder, Mayor; ice factory, address Citizens Bank."

Brooklyn, N. Y.—Specifications are being prepared by Chief Engineer Van Buren, of the City Works Department, for the construction of a water tower on Mount Prospect, at a cost of $65,000, and for laying a 48-inch water main from the Ridgewood reservoir with 36-inch and 30-inch branches, at a cost of $400,000.

Rutherford, N. J.—The Hackensack Water Company has made a proposition to the Borough Council to supply this place with water, the cost to be about $15 per hydrant. Councilmen Alyea and Warner were appointed a committee to select two citizens, and the committee of four to investigate the plan and report to the Council.

Pittsburg, Pa.—The agitation on the South Side for a better and more abundant supply of water for that section of the city has resulted, it is said, in the announcement that a Citizens' Water Company is to be organized for the purpose of supplying Knoxville, Allentown, Beltzhoover Borough and Mt. Oliver. It is also reported that the company has already secured permission from the township authorities to run an inlet pipe from the Monongahela River, above Beck's Run, up through the township to Southview Place, where the reservoir will be located. It is proposed to fix the capital stock at $200,000 at present. Ferdinand Berry, C. E. Succop, Henry Miller, and others, of this city, are mentioned in conection with the new project.

South Orange, N. J.—The following proposals for the construction of the water distribution system at this place were opened September 17, by C. Ph. Bassett, C. E., Engineer-in-Charge: Dowd & Rice, $4,740.50; Ludwig Batt, $5,698; W. F. Linman, $6,239; T. M. Lesher, $6,379.50; H. H. Holmes, $6,494; Small & Berry, $6,525. Thielman & Co., $7,199; George P. Olcott, $7,852.50; Donato Cuozzo, $9,159; Rooney & Bergin, $18,329.

Philadelphia, Pa.—Director Wagner appeared before the Council's Committee on Water September 16, and recommended the expenditure of $700,000 on improving the water-works system. On the directors' recommendation the amount was allowed, and the work will soon proceed.

New York City.—The Aqueduct Commissioners have awarded the contract for building the earth and masonry work of the auxiliary dam of Reservoir D, at Carmel, to M. S. Coleman, the lowest bidder, at $83,092.58.

Gainesville, Ga.—City Clerk E. P. Chambers writes: "We have let contracts as follows: Stand-pipe to Tippitt & Wood, Phillipsburg, N. J.; pump and boiler to Duane Pump Company, Holyoke, Mass., and pipe to South Pittsburg Pipe Works, South Pittsburg, Tenn. This completes the job except laying the pipe."

Algona, Iowa.—The following bids for the construction of a complete system of water-works were received by W. B. Quartor, City Clerk, September 1: Harrison & Hawley, St. Paul, Minn., $7,850; N. S. Wind and Engine Company, Batavia, Ill.; $9 990; Fairmont Turner, Nevada, Iowa, $9,000; Fairbanks, Morse & Co., St. Paul, $8,439. Contract awarded to Harrison & Hawley.

Oxford, N. C.—City Clerk F. B. Hays writes: "The water-works question has been much agitated in our town, and a few weeks ago our Board of Town Commissioners, in answer to a petition of citizens, called an election on the question of borrowing $50,000 to build water-works. The petition was withdrawn, however, and the election has not been held. The town now contemplates letting the franchise to a private corporation, but nothing definite is looked for for some time yet."

Hamilton, Mass.—Town Clerk Otis F. Brom writes: "I understand that some party has been in town to see if the town would grant the privilege of putting in water-works. The town has taken no action."

Jersey City, N. J.—The Board of Trade has adopted a resolution calling the attention of the city authorities to the present condition of the water supply, and demanding prompt action to secure a better and a cleaner service.

Blue Hill, Neb.—The following were the successful bidders for the construction of a system of water-works received by A. A. Richardson, Consulting Engineer, September 11: Porter Boiler Manufacturing Company, Chicago, stand-pipe, $4,600; John McCarthy, Wymore, Neb., base of stand-pipe, $1,000; South St. Louis Foundry and Pipe Company, pipe, $34.10; National Tube Works Company, Chicago, hydrants and valves, $711.

Winchester, Tenn.—City Clerk T. A. Embry writes: "Henry Jackson, of Nashville, is talking of putting in water-works at this place."

Hempstead, N. Y.—It is probable that improvements will soon be made in the local water-works system.

Water-Works.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Toledo, Iowa; Dallas, Tex.; Allegheny, Pa.; Atlanta, Ga.; Sutton, Neb.; Fulton, Ky.; Dallas City, Ore.; Ellsworth, Kan.; Austin, Tex.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

Oakland, Cal.—Numerous sewer extensions are to be made at this place.

White Plains, N. Y.—Edward D. Bolton, of No. 44 Broadway, New York, has been appointed chief engineer of the construction of sewers at this place. The work has been commenced and is progressing rapidly.

Orange, N. J.—A meeting of the Joint Committee of the Common Council and the Citizens' Committee on Sewerage was held last week, when the proposed improvement was discussed informally. It was decided to hold a public meeting in the Council Chamber at at early date, to which citizens and taxpayers are invited to be present.

Calais, Me.—Mayor C. W. McCullough writes: "We have employed W. E. McClintook, C. E., Court Street, Boston, to make survey and furnish with plans for complete sewerage of our city. We have not yet received plans, and it is getting so near close of season that probably not much will be done this year. We do not intend building our sewers by contract, and at once shall build part each year and under supervision of our Street Commissioner."

Jersey City, N. J.—It is said that all obstacles which have existed regarding the construction of a joint sewer between this city and West Hoboken have been removed and that the undertaking is about to be commenced. For particulars address Mayor Cleveland as above.

Tarrytown, N. Y.—Edward D. Bolton, of No. 44 Broadway, New York, has been put in charge of the construction of the sewerage system as chief engineer. The work is well under way and will soon be completed. Messrs. Van Vranken & Duell have the contract.

Mount Vernon, O.—Important improvements and extensions are to be made to the sewerage system at this place. Particulars can be had by addressing City Engineer Alexander Cassil, as above.

Dayton, O.—The plans for the sewerage of this city, now being prepared by Messrs. Cady Staley & Pierson, of Cleveland, with Rudolph Hering as consulting engineer, are nearly completed.

Roanoke, Va.—Rudolph Hering, of New York, has been retained to make a plan for the sewerage of this place. City Engineer Dunlap is now making surveys.

Somerville, N. J.—The following proposals for constructing approximately four miles of sewers, at this place, were opened September 8, by Carroll Ph. Bassett, of Newark, N. J.: W. F. Aid, Hoboken, N. J., $31,394; C. W. Hunt, New Rochelle, N. Y., $28,319.90; Geo. E. Clark, New York City, $25,174 60; P. H. Harrison, Newark, N. J., $17,576; James McGuire, Newark, N. J., $18,782.50; J. E. Hillpot, Philadelphia, Pa., $26,128.05; P. F. Hawman, Reading, Pa., $26,615.61; Pt. Rehill, Jersey City, N. J., $26,077.65; Small & Berry, New York City, $19,184.60; Richardson & Farrier, Somerville, N. J., $23,291.30; Charles H. Coleman, New York City, $20,720.33.

Marion, O.—John W. Hill, civil engineer, of Cincinnati, O., is in conference with the authorities of this place regarding a sewerage and drainage system.

Chicopee, Mass.—The Selectmen of this place have decided to advertise for proposals for constructing about 2,000 feet of 24-inch sewer.

Amsterdam, N. Y.—Considerable sewer work is to be done at this place. Address the Sewer Commissioners for particulars.

Sewers.—See our Proposal Columns for information regarding the construction of sewers at the following places: Albany, N.Y.; Iron Mountain, Mich.; Davenport, Iowa; Key West, Fla.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns

Fulton, Ill.—The Lyons and Fulton Bridge Company has been incorporated here to construct a bridge across the Mississippi River between the two points. Capital stock, $50,000. Incorporators, A. M. Hansen, S. W. Gardiner and others.

Troy, Ala.—A bridge is to be erected over Little Patsaliga River at this place. Address for particulars, J. B. Ewing, as above.

Chireno, Tex.—Reports say that a bridge is to be erected over the Atoyoc River at this place.

Roanoke, Va.—A communication from the Roanoke Gas and Water Company states that the contract for two bridges for the said company, across the Roanoke River, has been awarded to the American Bridge and Iron Co., of this city.

OSWEGO, N. Y.—Press dispatches of September 13, state that 40 bridges have been washed away by the floods in the eastern part of Oswego County.

RICHMOND, VA.—An exchange says: "The contract has been awarded to the Edge Moor Bridge Works, of Delaware, for building an iron and steel highway viaduct, 1,200 feet long and 40 feet wide and 75 feet high, connecting the properties of the Highland Park and Northside Land Companies with this place. The contract price is $74,000."

CARROLLTON, KY.—It now seems probable that the projected bridge over the Kentucky River, at this place, will be built. If established it will be built jointly by the Louisville, Covington and Cincinnati, the Carrollton and Louisville, and the Westport, Carrollton and Covington roads.

OCEANIC, N. J.—The Oceanic Bridge difficulty has at last been settled and the Board of Freeholders will proceed with the building of the structure.

WINONA, MINN.—The bill to erect a wagon bridge at this place has passed the Senate and will now become a law.

ROCKWOOD, TENN.—Reports say that the East Tennessee, Virginia and Georgia, and the Chattanooga Land, Coal, Iron and Railway Company are about to construct a $300,000 bridge at this place.

INDIANAPOLIS, IND.—The numerous railroads running through this city have decided to construct a viaduct across their tracks at a cost of $250,000. The matter is to be submitted to the City Council at its next regular meeting.

WASHINGTON, D. C.—The following bridge bills have passed the Senate: Senate bill to authorize the construction of a bridge across the Ocanee River in Georgia; House bill to authorize the Chicago, Henderson, Bowling Green and Chattanooga Railroad Company to construct a bridge over Green and Barren Rivers in Kentucky (with amendment); Senate bill to authorize the construction of a bridge across the Kentucky River and its tributaries; House bill to amend the act of July 16, 1889, authorizing the construction of a bridge across the Red River of the north.

NEW GRETNA, N. J.—The following bids for the erection of an iron bridge over the Mullica River were received by Charles A. Mathis, Chairman Board of Chosen Freeholders, September 15: Dean & Westbrook, New York City, low truss hemlock stringers and plank, $29,950; high truss hemlock stringers and plank, $31,900; low truss steel stringers and yellow pine plank, $32,200; high truss steel stringers and yellow pine plank, $33,875. Berlin Bridge Co., East Berlin, Conn., low truss steel stringers and yellow pine plank, $34,900; Groton Bridge Co., Groton, N. Y., $34,950; Pennsylvania Bridge Co., Beaver Falls, Pa., $35,390; New Jersey Steel and Iron Works, Trenton, N. J., $35,600; Pittsburg Bridge Co., Pittsburg, Pa., $37,300; King Bridge Co., Cleveland, O., no bond; Canton Wrought Iron Bridge Co., Canton, O., no bond; Wallis Iron Works, Jersey City, N. J., no plan.

WESTPORT, N. J.—The Bergen County Board of Freeholders has appropriated $3,500 for an iron bridge 60 feet long and 20 feet wide on the line of the highway.

WASHINGTON, D. C.—The Senate has just passed a bill authorizing the construction of a bridge across the Mississippi at Winona, Minn.

BRIDGES.—See our Proposal Columns for information regarding bridge construction at the following places; Reading, Pa.; Middlesborough, Ky.; San Antonio, Tex.

NEW DEPOTS.

PATERSON, N. J.—A new depot is to be erected at this place by the New York, Susquehanna and Western Railroad Company. Numerous car shops will also be erected.

GAS AND ELECTRIC LIGHTING.

INDEPENDENCE, MO.—The authorities of this place are about to ask for proposals from contractors for the public lighting of this city.

BIRMINGHAM, ALA. — The Consolidated Electric Light Company has been incorporated at this place, with a capital of $500,000. The incorporators are J. F. B. Jackson, R. M. Hulford and others.

TITUSVILLE, FLA.—It is proposed to establish an electric light plant at this place at an estimated expenditure of $10,000.

HULL, MASS.— The Nantasket Electric Light and Power Company has been organized for the purpose of establishing a lighting plant. A franchise for this city has been granted. Address Elisha Thayer for particulars.

BELLEVUE, KY.—An electric lighting plant is proposed for this place.

FALL RIVER, MASS.—Surveys are being made by Gilbert Hodges, C. E., of Boston, for an electric belt line road for this place.

FALL RIVER, MASS.—The Border City Manufacturing Co., of this place, will increase its electric light plant by 1,000 lights.

NEWARK, N. J.—The local gas companies will lay about four miles of additional gas mains this fall.

SPARTANBURG, S. C.—The local electric lighting plant is to undergo extensive improvements.

LUDLOW, VT.—The people of this place want electric lights.

JOLIET, ILL.—Articles of incorporation were filed September 5, for the Economy Light and Power Company, a consolidation of the Thomson-Houston and the Westinghouse Companies. Secretary, Treasurer and Manger, L. E. Ingalls, of this place.

SEATTLE, WASH.—The Heims Electric Light Co., has been incorporated at this place, composed of members of the Pacific Electric Light and the Commercial Electric Light Companies, E. C. Hilbourne, C. P. Stone and others. The capital stock is $500,000. It is intended to double the present plant in a short time and operate 105 arc and 3,700 incandescent lights, and spend $100,000 in improvements. Both light and power will be furnished.

MARTIN'S FERRY, W. VA.—Improvements are to be made to the local electric light plant.

PALMYRA, PA.—This place is to have an electric light plant.

OSCODA, MICH.—It is probable that the projected electric lighting plant for this place will be established at once.

PETERBORO, CAN.—At a recent Town Council meeting, a resolution was introduced to raise $11,000 to purchase a site for the works of the Edison General Electric Company.

RICHMOND, VA.—A resolution has been adopted asking the Council of this city to appropriate the sum of $75,000 to build an electric light plant.

CHICAGO, ILL.—The Burt Electric Light, Fuel and Power Company has been incorporated here, with a capital stock of $5,000,000, for the manufacture of incandescent dynamos, motors, etc. Martin C. Burt, Allen S. Bennett and J. L. Bennett, incorporators.

BERLIN, WIS.—The sum of $12,000 is to be expended on establishing an electric lighting plant for this place.

ELECTRIC RAILWAYS.—New electric railways are to be constructed and improvements are to be made to those already established at the following places: Cairo, Ill.; Sioux City, Iowa; Savannah, Ga.; Bloomington, Ill.; Chattanooga, Tenn.; Lancaster, Pa.

STREET-WORK AND PAVING.

MARION, N. C.—Street improvements to cost $10,000 are to be made at this place.

JOHNSON CITY, TENN.—The sum of $50,000 is to be expended for improving the streets at this place.

ALBANY, N. Y.—At a meeting of the Board of Contract and Apportionment, held September 15, the following proposals for street paving and sewers were opened: For the pavement of Allen Street with Trinidad asphalt from Central Avenue to Western Avenue: Barber Asphalt Company, asphalt per square yard, $3.10; curb per lineal foot, 80c.; circular curb per foot, 85c.; repairing asphalt at intersections, $1.90; filling per cubic yard, 35c.; excavation per cubic yard, 35c.; 15-foot sidewalks per foot, $1.85. Trinidad Asphalt Company, first item, $3.23; second, 95c.; third, 95c.; fourth, $1; fifth, 39c.; sixth, 23c.; seventh, $1.90. Contract awarded to the Barber Company. Sewer in Hawk Street, from Myrtle Avenue to the Beaver Creek sewer: John Doyle, 18-inch pipe, stone, per foot, $1.75; 12-inch iron pipe, $4.50; 6-inch vitrified, 75c.; 18-inch "Ys," $5; manholes, $60 each; lampholes, $95 each. Contract awarded to John Doyle.

WILMINGTON, DEL.— Considerable street paving is to be done at this place. Address the City Engineer for particulars.

WASHINGTON, D. C.—Considerable paving is to be done in this city at an early date. Address E. H. Tucker, of the Street Committee, for particulars.

BIDS OPENED.

WAUSAU, WIS.—The contract to build a court house in this city has been let to John Miller, of Wausau, at $48,500. Six Milwaukee contractors bid for the job.

SHELBYVILLE, IND.—The County Commissioners of Shelby County have opened bids for an orphan asylum to be erected at this place. The bidders: Louis F. Burton, of Indianapolis, $11,941; J. L. Fatout, Indianapolis, $11,944; St. John & Co. Shelbyville, $11,990; Wingate & Co., Shelbyville, $15,700; Victor & Co., Shelbyville, $13,339. All the bids were rejected as being too high. The commissioners do not want to exceed an expenditure of $10,000 in the erection of the building, and new bids will be received on that basis.

GOVERNMENT WORK.

PHILADELPHIA, PA.—The following bids for dredging in Philadelphia Harbor, Pa., for removal of Smith's and Windmill islands, were received by C. W. Raymond, Major of Engineers, U. S. Army, September 16: American Dredging Co., Philadelphia, $207,500; Frank C. Somers, Camden, N. J., $264,000; Penn Dredging Co., Philadelphia, $185,000, Baltimore Dredging Co., Baltimore, Md., $307,500.

GALVESTON, TEX.—The following proposals for the plumbing, etc., for the United States Custom House at this place were opened September 17, by the Supervising Architect of the Treasury Department: Crook, Horner & Co., Baltimore, Md., $8,839.20; May & Wammwright, Galveston, Tex., $10,900; Benjamin Whitney, Chicago, Ill., $9,423; Montgomery & Patterson, New York, $13,637; J. F. Dalton, Chicago, $9,236.55; V. E. Appleby, Galveston, $8,725; John Worthington, Philadelphia, Pa., $10,874.

INDUSTRIAL.

MADISON, ME.—The contract for the erection of the new mill for the Manufacturing Investment Company, of New York, has been let to the Berlin Iron Bridge Company, of East Berlin, Conn., whose designs were accepted. The building is to be of iron, 62 feet wide, 220 feet long, 4 stories high; the machine shop 72 by 172 feet, and the washing room 174 by 182 feet.

NICETOWN, PA. -The Midvale Steel Company have made a contract with the Berlin Iron Bridge Company, of East Berlin, Conn., for the erection of their new casting shop, 182 by 185 feet, with wings of 50 feet each. The building will have several 50-ton traveling cranes.

BUFFALO, N. Y.—The contract for the buildings of the Lake Erie Engineering Company at this place has been let to the Berlin Iron Bridge Company, of East Berlin, Conn. The buildings are to be of iron, and were designed by F. Felkel, civil engineer and architect, of Cleveland, O. The machine shop will be 180x185 feet, and the foundry buildings 185x225 feet.

WANTED.

TOO LATE FOR CLASSIFICATION.

CIVIL ENGINEER, EXPERIENCED IN SURveying, railroad work, sewers, etc., desires a position. Topographical and mechanical draughting a specialty. Address "B," 208 E 118th Street, New York.

DRAUGHTSMAN, WITH FOUR YEARS' EXperience, desires a permanent position in architect's office, with chance of advancement. Address SQUARE, Box 37, this office.

A YOUNG MAN WOULD LIKR POSITION as rodman. Five years' experience. Locality no object Can level. Address JOHN T. HYLAND, Jr., 112 Broadway, Sing Sing, N. Y.

WANTED.—A PLUMBER TO WORK ON lead or iron pipe; also two good boiler makers. Address W. J. BARNSTEAD, 20 West Main Street, Galesburg, Ill.

PROPOSALS.

Continued from page ii.)

PIPE AND RESERVOIR, Dallas City, Ore.—Proposals are wanted until October 8, for furnishing a quantity of wrought-iron pipe, special castings, etc., and for construction of a 3,000,000 gallon reservoir. Address M. T. Nolan, Secretary of the Board of Water Commissioners, as above.

PROPOSALS.

Notice to Paving Contractors.

PROPOSALS FOR MACADAMIZING SEVeral streets will be received by the Village of MT. VERNON, N. Y., up to September 30. Plans and specifications can be seen at office of Commissioner of Public Works, Mt. Vernon, N. Y.

JARED SANDFORD,
17 Village President.

SEWERS, Albany, N. Y.—Proposals are wanted until September 27, for the construction of sewers and drains at Watervliet Arsenal. Address Lieut.-Col. F. H. Parker, U. S. A., as above.

LIGHTING, Keokuk, Iowa.—Proposals are wanted until September 25, for lighting the public streets, etc., of this city for a period of five years. Address Rollin Clark, Clerk of Council, as above.

SEWERS, Davenport, Iowa.—Proposals are wanted until September 30, for the construction of certain sewers. Address Joe L. Hebert, City Clerk, as above.

WATER-WORKS, Fulton, Ky. — Proposals are wanted until October 1, for the construction of a system of water-works for this place. Address George Cadogan Morgan, C. E., No. 15 Major Street, Chicago.

BRIDGE, Middlesbrough, Ky. — Proposals are wanted until October 1, for the construction of an iron bridge. Address D. N. Mason, as above.

FLAGGING, New York City. — Proposals are wanted until September 25, for flagging numerous streets. Address the Department of Public Works, as above.

WATER-WORKS AND ELECTRIC LIGHT, Canton, S. Dak.—Proposals are wanted, no date specified, for furnishing a water-works and electric light system for this place. Address J. M. Zeller, Mayor, as above.

STREET RAILROAD, Cincinnati, O.—Proposals are wanted until October 2, for the construction of street railroad route No. 22, this city. Address Edwin Henderson, City Clerk, as above.

WATER-WORKS, Sutton, Neb.—Bids will be opened October 1, for a water-works system, apply to A. A. Richards, Engineer, Lincoln, Neb.

SEWERS, Dayton, O.—Sealed proposals will be received at City Commissioner's office, for constructing about 12 miles of pipe and brick sewer, according to plans on file in said office.

HEATING AND VENTILATING, Quincy, Ill.—Proposals are wanted until October 4, for the heating and ventilation of the new city hall building at this place. Address Harvey Chatten, architect, as above.

SCHOOL, Canton, O.—Proposals are wanted until October 15, for the erection of a brick school building. Address L. W. Radel, Clerk of the Board of Education, as above.

WATER-WORKS, Ellsworth, Kan.—Proposals are wanted until October 10, for the construction of a system of water-works. Address Chairman Board of Trustees, G. A. R., as above.

N s Stagg st, 118 w Rogers st, 6 fr dwells; cost, $25,000 all; o, J Schneider; a, Th Engelhardt.

The Commission having charge of the erection of the new Thirteenth Regiment armory has adopted Architect Daus' plans, with certain modifications. Work on the new building will be begun shortly.

ALTERATIONS—BROOKLYN.

Henry st, n w cor Amity st, br extensions, interior alterations; cost, $20,000; o, L I College Hospital; a, W B Tubby; b, J Thatcher and L W Seaman, Jr.

MISCELLANEOUS.

ADAIR, IA.—Adair County has decided to build a $25,000 court house.

AUSTIN, TEX.—West wing St Edward's College; cost, $20,000; o, Rev P J Hurth, President; a, N J Clayton, Galveston;b, not let yet.

BOSTON, MASS.—776–784 Washington st, br mercantile bldg; cost, $75,000; o, R Sherburne; b, Richardson & Young.

786–790 Washington st, br alteration; cost, $9,000; o and b, same as above.

Wrentham st, 3 fr dwells; cost, $12,000, o, a and b, J I Stewart.

Westminster st, br aparts; cost, $14,000; o and b, Ira Bradley; a, S S Woodcock.

219 Shawmut av, br alteration; cost, $7,000; o, George H Jacobs; a, S D Kelly; b, J Murphy.

Dromey av, 2 fr dwells; cost, $8,000; o, Cath Drummey; b, W W Dromey.

Humboldt av cor Howland st, fr dwell; cost, $7,800; o, Walter R Meins; a, E I Wilson; b, H C Allen.

Walter st cor Peters st, 2 fr dwells; cost, $7,000; o, a and b, H D Van Norden.

536 Beacon st, br dwell; cost, $30,000; o, G Z Silsbee; a, W T Peters; b, C H Dodge.

BUILDING INTELLIGENCE.

BRIDGEPORT, CONN. — McMahon & Wren, merchants, have accepted plans drawn by a local architect for a new hotel, to be erected on what is known as the Sterling homestead, to cost $150,000.

Elmwood av, fr dwell; cost, $7,500; o, Thomas Boudren; a, H A Lambert; c, James Burnes; m, Thomas Young.

CHICAGO, ILL.—Clark and Oakdale, theater, halls and stores; cost, $200,000; o, The Pythion Temple Co; a, J J Kouhn; b, C B Williams.

1906 Wellington, br dwell; cost, $15,000; o, C W Lasher; a, A M F Colton.

1723–29 York, br dwell; cost, $16,000; o, Louis Willie; a and b, J L Woollacott.

1115 N Clark, br dwell; cost, $8,000; o, Edw M Landis; a, H C Hansen; b, Siebold & Alke.

4352 State, br store and flats; cost, $10,000; o, Jos Schilling; a, J F & J P Doerr; b, W Reinert.

66th and Sherman, br dwell and flats; cost, $40,000; o, McConley & Swartman; a, J Eighlien; b, C A Leke.

45th, Court and State, br flats; cost, $14,000; o, Albert Vingens; a, Bargerbush & Koster; b, Wm Reinert.

43d and Carpenter, br warehouse; cost, $19,000; o, Armour & Co.

47th and Throop, barns; cost, $16,000; o, W E Perrin.

4509 Grand boul, br dwell; cost, $14,000; o, M C Schroneman; a, Flanders & Zimmerman; b, A D Elmers.

5417 Jefferson av, br dwell; cost, $8,000; o, J Abrams; a, M L Beers; b, O Hero.

5609 Indiana av, br flats; cost, $11,000; o, M P Commings.

789–91 Blue Island av, br store and flats; cost, $10,000; o, Herman Beifuss; a and b, C W Karbach.

850–56 W Polk, br flats; cost, $13,000; o, J R Madison; a, J N Tallon; b, F Townsend.

1245 Washington boul, br dwell; cost, $11,000; o, Adam Kolb; a, C L Stiles; b, J D Edwards.

369–71 S Lincoln, br flats; cost, $9,000; o, M L Prismann; a, E Rockwell; b, L Sommers.

201 W Erie, br store and flats; cost, $16,000; o, B Henderson; a, R A Denell; b, Jno Olson & Son.

495 Lincoln, br flats; cost, $8,000; o, W Buras; a, Anton Chevat; b, F Uekola.

888–90 W Adams, br dwell; cost, $15,000; o, Isaac Hoffert; a, Edbrooke & Burnham; b, Jno O'Connell.

3100–08 Groveland av, apartment bldg; cost, $250,000; o, Howard & Berwin; a, Jno Duncan; b, M J Benson.

165–67 Morgan and 282–90 Jackson, br store and flats; cost, $60,000; o, Howard & Berwin; a, D S Pentecost; b, Alex McKadway.

3648 Wentworth av, br store and flats; cost, $8,000; o, Peter H Kaup; a, J F & J P Doerr; b, Bock & Krause.

Dearborn and Erie, additional story; cost, $8,000; o, Geo F Harden; a, L G Hallberg; b, N Hoffman.

4730 Evans av, br dwell; cost, $10,000; o and b, Custard & Logan; a, E C Hentz.

4030 Lake av, br dwell; cost, $28,000; o, A Strickland; a, A Gronner; b, W H Cameron.

Greenwood av and 45th, br dwell; cost, $10,000; o, Frank Hecker; a, Robt Rae, Jr; b, B G Robinson.

170-72 Oakwood boul, br flats; cost, $16,000; o, Smith & Jones; a, Thomas & Rapp; b, M McMillan.

4737-39 Lake av, br dwell and barn; cost, $12,000; o, H C Fisher; b, Bernritter Mfg Co.

77-9 W Ohio, br store and flats; cost, $8,000; o, Dennis Mitchell; a, Wm Ohlbober; b, P Schroeder.

Paulina and Augusta, hop room; cost, $12,000; o, West Side Brewing Co; a, F Hansen.

North av and Rockwell, br store and flats; cost, $11,000; o, Edw Michlieu; b, Fred Hansen.

899-903 31st, br school; cost, $16,000; o, P L Brielmann; a, J F & J P Doerr; b, Gulrich Bros.

BUILDING INTELLIGENCE.

CHICAGO, ILL.—Throop and Madison, colliseum; cost, $20,000; o, C H Wyman; a, J M Haskins; b, McGraw & Muller.

538 Washington bd, br dwell; cost, $11,000; o, M M Clark; a, S M Roudolph; b, McGraw & Mullin.

412-14 27th, br flats; cost, $9,000; o, Wendel & Pebbles; a, E B Eigendroth; b, R H Morgan.

4516 Champlain av, br dwell; cost, $9,000; o, M E Smith; a, A A Smith.

118 Lake Shore Drive, br dwell; cost, $45,000; o, Mrs B Armour; a, Barling & Whitehouse; b, Barry & Rodatz.

306 Sheffield av, br flats; cost, $8,000; o, Henry Ruder; a, A Woerner; b, C J Westpool.

1202-06 Milwaukee av, br store and flats; cost, $16,000; o, Fred Housen; a, Hy Kley; b, Housen & Widkie.

1648 W 12th, br store and flats; cost, $10,000; o, W A Fox; a, Hetherington & Ward; b, Krieg & Son.

254 buildings costing less than $7,000 each.

CINCINNATI, O.—John G Morris is having the plans made for a wire foundry, to be 6 stories, br, and cost $50,000, to be built at Canal and Vine sts.

Coleraine av and C H & D R R, 3½-story br dwell and store; cost, $7,000; o, John Bruckman; a, Wm Shroeder.

Central av, near Baymiller st, 2-story br addition to tannery; cost, $5,000; o, Wm C Kennett.

3-story br addition to *Enquirer* Printing office; cost, $11,000; o, *Enquirer* Co; a, S Hannaford's Sons.

563 Race st, 4-story br store and flats; cost, $11,000; o, Phillip Klopp; a, G & A Brink.

8th and Harriet sts, br boiler and engine room; cost, $7,000; o, Blymer Ice Machine Co; a, Brice & McMiller.

3 6-story br bldgs for rectifying and distilling purposes; cost, $40,000; o, Rheinstrom Bros; a, A O Elzner.

McMichen and Ohio avs, Phillipus Evangelical Protestant Church; cost, $35,000; c, Wm Miller.

Harrison and Western avs, 3-story br iron and brass foundry; cost, $40,000; o, Joseph Joseph; a, S Hannaford's Sons.

COLUMBUS, O.—Broad st, br and st business block; cost, $10,000; o, Jas T Zollinger.

37 dwellings costing $68,100.

DECATUR, ILL—A vote will be taken here on the question of building a $100,000 court house.

DENVER, COL.—Gaylord, bet Colfax and 16th av, br dwell; cost, $7,500; o, Doone Chamberlin; a, Burhandt & Vaughn.

13th av, cor Elizabeth, br dwell; cost, $11,000; o and a, S Benson.

Larimer, cor 24th st, br store; cost, $11,000; o, A Miller; a, J J Huddart.

Curtis, bet 20th and 21st, br addn; cost, $12,654; o, City of Denver; a, Building Inspector.

Broadway, bet 2d and 3d avs, br double dwell; cost, $10,000; o, Mrs Wm Daily; a, Varian & Sterne.

DETROIT, MICH.—Grand River av, bet 4th and 5th sts, block 3 3-story br stores and flats; cost, $25,000; o, Robt Bell; a, Harry J Rill.

Cor Woodward av and Montcalm st, block 5-story br stores and flats; cost, $25,000; o, Jas Burtenshaw.

N w cor Larned and Shelby sts, 8-story br business block; cost, $50,000; o, *Evening News* Ass'n.

Willis av, bet Antoine and Hastings sts, 2-story br res; cost, $8,000; o, Stephen Baldwin.

Calhoun st, bet Beaubien and Antonio sts, br church (enlarged and remodeled); cost, $8,000; o, Ebenezer African M E Society; a, Harry J Rill.

N w cor Champlain st and Meldrum av, 3-story block of 3 br stores and flats; cost, $8,000; o, Jas E McDonald; a, G W Myers.

ELKHART, IND.—The Elkhart *Review* will erect a building specially designed for the printing business.

BUILDING INTELLIGENCE.

FITCHBURG, MASS.—Cor Middle and 2d sts, 2-story br parochial school; cost, $15,000; o, St Bernard parish; b, John H Kirby.

GALESBURG, ILL.—Wm Wolf, architect, has prepared plans for a $10,000 residence for Thos McKnight.

GRAND RAPIDS, MICH.—Cor Fountain and Barclay sts, br and s church; cost, $20,000; o, First Reformed Society; a, Rush & Son; b, Vanden Boogert Bros.

HOLYOKE, MASS.—Maple st, br addition to block of tens; o, Mrs. J E Cragin; a, G P B Alderman.

MEADVILLE, PA.—Plumb Alley, 50 feet south of Walnut st, chapel for the Episcopalian Church; cost, $8,000; o, Episcopalian Society, Rev Israel has charge; a and b, W E Morrison.

MILWAUKEE, WIS.—N e cor Biddle and Market sts; business block; cost, $25,000; o, W T Jacobi; a, C F Kinger; b, Hamboldt & Froemming.

Teutoma and Center sts, business block; cost, $8,5000; o, F Brembach; a, H P Schnetzky; b, Kern Bros.

NEW YORK CITY.—The Board of Estimate and Apportionmeot has approved the plans for the extension of the Metropolitan Museum of Art submitted by General Di Cesnola.

BASSAIC CITY, VA.—Store and warehouse; cost, $10,000; o, Crall & Brien; a, J C Smith, Harrisburg, Pa; b, contract not let yet.

PALESTINE, TEX.—R C Church; cost, $25,000; o, Rev C M Thion; a, N J Clayton & Co; b, not let yet.

PEORIA, ILL.—The Free Methodist denomination has decided to build a large church here. Plans have not yet been drawn.

PROVIDENCE, R. I.—Stewart st and Warner's lane, 4-story br bldg; cost, $20,000; o, American Electrical Works; b, J W Briggs.

Sprague st, 2-story br observatory; o, Mechanical Fabric Co; b, Freeborn Johnson.

Dartmouth av, 2 fr tens; o, Mary E Price; b, Richard Hayward.

Cooke and Angell sts, fr dwell; o, H M Bron estate; a, Goulot & Angell; b, Chas H Swan.

Benefit st, alteration in fr dwell; o, Jenkins estate; a, Stone, Carpenter & Willson.

Prospect and Watermane sts, br and stone gymnasium; o, Brown University; a, same as above.

Olneyville st, fr schoolhouse; o, St Teresa Church; a, same as above.

SIOUX CITY, IA.—Cor Pearl and 9th sts, 2 double dwells; cost, $7,500; o, J A Magoun; a, G G Baldwin; b, Weinees & Nelson.

Cor 11th and Jones sts, fr dwell; cost, $10,000; o, T Galbraith; a, E Loft; b, C K Poor.

Cor Jackson and 20th sts, fr dwell; cost, $11,000; o, L E Skinner; a, J P Martin; b, Payette & Corneau.

SALT LAKE CITY:—West Temple st, 6-story hotel build; cost, $750,000; o, Syndicate; a, Adler & Sullivan; b, Elias Morris and H Probst.

WHEELING, W. VA. — Lantern factory; cost, $15,000; o, Company; a, C Hamilton; b, not let.

Rectory bldg, cost, $12,000; o, Mathews Church; a, E Franzheim; b, not let.

WORCESTER, MASS.—Cor of Chatham and High sts, br and s bldg; cost, $60,000; o, Young Women's Christian Ass'n; a, S C Earle; b, not let.

BUILDINGS.—There is nothing over $7,000 in value to report at the following places: Geneva, N. Y., Youngstown, O.; Charleston, S. C.; Newark, O.; Poughkeepsie, N. Y.; Allentown, Pa.; Pine Bluff, Ark.; Binghamton, N. Y.; Detroit, Mich.; Topeka, Kan.; Montclair, N. J.; Pottstown, Pa.; Dennison, O.; Pottsville, Pa.; Wilkesbarre, Pa.; Allegheny, Pa.; Dayton, O.

THE ENGINEERING & BUILDING RECORD

AND

THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22. NUMBER 17. — PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.

NEW YORK, SEPTEMBER 27, 1890.
LONDON, OCTOBER 11, 1890.

SINGLE COPIES, TEN CENTS.
Subscription, $4.00 per year in advance, post paid. — IN AMERICA.
Subscription, 25s. per annum in advance, post paid — IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE 1050 DREXEL BUILDING.
TERMS, $4 PER YEAR, IN ADVANCE.
25s. in GREAT BRITAIN. Other Foreign Countries $6.
Postage Paid.

SPECIAL OFFERS.

DOUBTLESS many of our subscribers have a friend who thinks of subscribing to THE ENGINEERING AND BUILDING RECORD for the coming year, and as every paper, however successful it may be, desires to increase the number of its subscribers, the following offers are made, to hold good during October, November and December:

First.—Any present subscriber can have his subscription extended one year by sending us $7.25, accompanied by the name and address of a new subscriber who is not now buying THE ENGINEERING AND BUILDING RECORD of a newsdealer.

Second.—Any present subscriber can, under the conditions mentioned in first offer, have his own yearly subscription for $2 by sending us, with his renewal, two *new* names and $10, or for $1, by sending three new names and $13.

THE CHEAPEST FORM OF LIGHT.

IN the ordinary means of artificial lighting there is evolved a great amount of energy in the form of heat, which is not applied to any useful purpose, and which, therefore, is said to be wasted. In common candle, lamp, and gas flames this waste ordinarily exceeds 99 per cent. of the total energy developed, and although less in the electric light, it is still very much the larger part. The problem, from an economic point of view, is how to produce light with the least amount of heat.

In nature this seems to be effected in certain living organisms, such as the glow-worm or the fire-fly, the light of which is not accompanied by a sensible development of heat; but until recently the quantity and quality of the heat which accompanies such light had not been measured or demonstrated. This has now been done by Prof. S. P. Langley, the Secretary of the Smithsonian Institution in Washington, and the paper in which he describes the results obtained is a very interesting and suggestive one. The measurements of the heat evolved were made by means of the bolometer, an exceedingly sensitive instrument devised several years ago by Professor Langley for the purpose of measuring the heat radiated to us by the stars. To give an idea of the sensitiveness of this instrument, and of the exceedingly small amount of heat radiated with the light of a tropical fire-fly, it is stated that "if that rate of radiation from a lamp-black surface one square centimeter in area, which represents the amount of heat necessary to raise one kilogramme of water 1° Cent. in one minute, be taken as a unity—*i. e.*, one calorie, then the luminous radiation of the fire-fly's heat per square centimeter of exposed luminous surface is about 0.0004 calorie in ten seconds. Of course only a small portion of this heat could reach the bolometer, and that which did fall on it in ten seconds would have raised the temperature of an ordinary mercurial thermometer, having a bulb one centimeter in diameter, less than one four-hundred-thousandth part of 1° Cent."

Yet even this small amount of heat received on the instrument consisted of two different kinds which must be separated — namely, the ordinary animal heat and that specially connected with the luminosity. This separation was accomplished. The result was to show that the insect light was accompanied by approximately one four-hundredth part of the heat ordinarily associated with the radiation of ordinary illuminating flames, or in other words, that nature produces the light of the fire-fly with only about one four-hundredth part of the cost of the energy which is expended in a candle flame giving the same light. Professor Langley concludes that there is no reason why we may not hope to yet discover a method of obtaining an enormously greater result than we now do from our present ordinary means of producing light.

NEW YORK'S NEW PAVEMENTS.

THE repaving of one of New York's principal streets—Broadway—was commenced this week and will, it is thought, be completed from the Battery to Chambers Street by the early part of November. Previous to the laying of the new pavement whatever changes and repairs may be necessary in the various pipe systems under the street surface are supposed to be made, and the underground work for the Broadway cable road is to be put in such shape that there need not be any subsequent disturbance of the street. This, at least, seems to be the good resolution which is popularly supposed to have been made, and Public Works Commissioner Gilroy is credited with having expressed himself to the effect that after the new pavement is down he will turn a deaf ear to all applications for permits to tear it up again, no matter how specious the pretext.

Every one will acknowledge that this is just as it should be, but the New York citizen has learned by sad experience that all such assurances must be accepted with a goodly share of allowance for what are very conveniently termed "unforeseen contingencies." It would be a fair spectacle indeed to have at least one of New York's down-town thoroughfares in an undisturbed condition for a period measureable by weeks or months, and Commissioner Gilroy will, no doubt, receive praise without stint if he will be able to restrain, as he proposes, the earth-burrowing corporations and others who have made themselves so uncomfortably prominent in the past.

Now that the work of repaving is just beginning, the application of a little foresight cannot be too strongly commended, and with reasonable care, and firm action of the authorities, New York ought soon to have a Broadway pavement which would be in creditable condition even after a few years' use.

UNWORTHY ATTACKS ON CITY ENGINEERS.

CITY ENGINEER RUNDLETT, of St. Paul, Minn., has recently been the victim of charges, given publicity in a local paper, such as all engineers holding similar positions are from time to time liable to.

There has of late been considerable sewer building in St. Paul. The City Engineer's specifications, as it was necessary they should do, required hard burned brick, and brick that would stand a certain test. To meet the requirements of these specifications it was necessary that brick should be purchased from brick yards elsewhere than in St. Paul, whereupon a manufacturer, in an interview published in a local paper, accused the City Engineer of being responsible for the practical destruction of the local brick industry, and the fact that certain contractors are now working for the city who once held positions under the City Engineer is cited as a case where favoritism is likely to occur.

After giving publicity to these charges, which are about on a par with those constantly made by disappointed contractors and manufacturers of something that they fail to succeed in selling to a public officer, the journal publishing them allows the City Engineer to say that his duty was to build a good sewer, and to use the required materials necessary to do it without regard to the locality from which they came. Moreover, he plainly pointed out that the brick used by builders in the city also came from other localities, so that, even to the average reader, there would seem to be the amplest justification for his statement that the St. Paul bricks were too soft for the city's purposes.

It is a melancholy fact that an engineer striving to serve his community is at any time liable to have the columns of a local paper open for just such attacks on his character and reputation, and that too many people are only too quick to jump at the conclusion that he can have no motive in making a decision regarding the choice of materials other than a mercenary or a corrupt one.

CABLE *VS.* ELECTRIC TRACTION.

IN a pamphlet on "The Return of Power in Electric and Cable Traction," prepared some months ago by A. Bryson, Jr., of New York, cable and the more commonly known overhead electric traction systems for street car work are compared, with the view to establishing, as nearly as possible, their relative positions in point of cost and efficiency. The pamphlet has been specially commended to our attention because of the reference to electric storage battery systems for street car propulsion made in our issue of August 9, 1890, and the tabulated statement there published, giving the costs of electric, cable and horse traction, as calculated for the Fourth Avenue street car line at New York, on which the storage battery system has been used for some time. The figures published were presumably determined for a known set of conditions, but were not given as correct and final measures of the values of the different systems considered. As a matter of fact it was intimated that they might be found to differ from those subsequently found in actual every-day work.

General comparisons can in no case be expected to give definite values, and in Mr. Bryson's pamphlet, therefore, the data submitted can be accepted only as general indications of possible wastes in the two methods of power transmission which he compares. What he has to say, however, is not the less interesting. We extract the following from the pamphlet:

Beranger, an engineer in the employ of the German Government, has estimated the return of energy in different systems of transmission as follows:

Dist. in Feet.	By Electricity.	By Cable.
1,640	68 per cent.	93 per cent.
3,280	66 " "	90 " "
16,400	60 " "	60 " "

In street railway traffic the power is not all transmitted to a given point, as in the above table, but is distributed all along the line; hence the comparative economical distance for cable as given above will be very much exceeded when street railway service is to be provided for. And it must be remembered that transmission of power only is considered exclusive of the loss in converting the electrical into mechanical energy by the motor.

Mr. Deprez, although a most ardent advocate of the high-voltage system of transmission, has realized only about 33 per cent. of the original energy at a small distance.

The loss in the dynamo is the next to be considered, and the following extract from Mr. J. T. Sprague's work on electricity will serve:

"The efficiency of a dynamo machine is often reckoned from its capacity as a converter of mechanical energy into electrical; that is, by the formula $C^2 \times R$. But the electric energy expended within the machine is as much waste as the mechanical friction. The true efficiency is represented by the ratio of the energy in the external circuit to the mechanical energy expended in driving. . . . If we call the horse-power employed in driving 100, then we shall generally have about 10 to 13 per cent. absorbed in friction and local currents, which would reduce the efficiency of the particular Burgen,* as stated above, to 63 per cent., while the various tests made at public trials show that this true efficiency, as developed in different machines, actually ranges down to 30 per cent. only. The efficiency is greatest in large machines and when the machine is used under the conditions for which it was designed."

Next as to the efficiency of motors. High velocity of rotation is a prime condition of efficiency, and to that end the moving parts should be as light as possible. Therefore, when running at their proper full speed they are doing their best and most economical work; but when starting, or running slowly as is so often the case when passing along crowded city streets, the conditions are most unfavorable and the expense increased.

Professors Ayrton and Perry (England) give the efficiency of various motors with which they experimented as follows:

Motor.	Weight in lbs.	Resistance.	Current.	Revs. per min.	H. P.	Efficiency.
Griscom	2.5	1.1	3.9	513	.00225	.0542
Gramme Armature, Sieman Field	30.8	.973	5.4	932	.0275	.296
Ayrton & Perry	37	.2	25.9	1,880	.215	.383
De Meritens	72	.850	10.6	660	.154	51
Siemens	519	. . . .	......	900	4.90	.746

---

* This is the machine which he previously experimented with and gives diagrams and calculations for, and which indicated a useful work of 73.5 per cent.

These figures do not relate to the cost of putting the energy into the motors. And yet some electricians claim 90 per cent. efficiency for their motors, while others, more modest, state 80 to be the figure. However, we will accept these figures and see what the result is, starting with the engine cylinders and ending at the gearing side of the motor. The friction loss of the engine we will assume to be 10 per cent., the horse-power in the cylinders as one. Then there will be delivered to the dynamo 90 per cent. For the dynamo we will allow 80 per cent., and it will then deliver to the conductor 80 per cent. of 90 per cent. — 72 per cent. Counting loss in transmission as only 25 per cent., which, as has been previously shown, is much less than disinterested experimenters place it, we shall have delivered to the motor 72 — 25 — 54 per cent.; and allowing 80 per cent. again for the motor, the resulting net return, to apply to driving the gearing on the car, will be 54 × .80 — 43.2 per cent of the original power in the engine cylinders. This will diminish as the work to be done increases and the motor approaches its maximum capacity, as for instance on grades, and it is exceedingly doubtful if any such returns have been practically realized.

The cost of power stations will be about the same for cable as for electricity; leaving the interest on street construction and price of fuel to determine the result, due consideration being given to dangers, possibility of breakdowns, grades, and climatic effects.

The cost of an electric street construction increases with the business for which it is proportioned, due to the varying size and weight of conductors, etc.; whereas the cable is the same whether light or heavy traffic is contemplated, varying only with the character of the street through which it passes.

The storage battery is not considered at all in this, though a correspondent, in a letter accompanying the pamphlet, takes exception to the figures published in our issue of August 9, pointing out that nobody knows what the depreciation and repairs in the storage battery system amount to; that no storage system has ever yet given better returns than direct transmission; that the cost of the special features of the storage battery car would, at a low estimate, be $24 40, as compared with $300 for the cost of equipping a cable car with grips and other fixtures; and that, as the sizes of the horse, electric and cable cars are not the same, the costs of the cars do not admit of reasonable comparison. As regards the last, it may be well to state that the storage battery cars on the Fourth Avenue line differ but little in size, if at all, from the ordinary horse-car used on that line, and that a large number of cable cars in some places, Philadelphia, for example, are of ordinary horse car proportions. From all this, therefore, there would seem to have been available a very good basis for reasonable comparison. However, it is not at all necessary for us to enter into these details. The point to which we wished to give prominence was that, taken altogether, the storage battery system for street car work could, as apparently shown by experience at New York, be operated safely, successfully, and profitably. That much being established, there was little else to say as to which of the several systems claiming public approval for city street service was most commendable. There could be but one choice.

THE A. L. HOLLEY MEMORIAL.

THE Committee of Arrangements connected with the erection of the memorial bust of Alexander L. Holley, in Washington Square, New York, are making elaborate arrangements for the unveiling ceremonies, which are to take place on October 4. The various societies interested in the affair will assemble at Chickering Hall at 2 P. M., when James E. Dredge, of London, editor of *Engineering*, will deliver an address. The American Institute of Mining Engineers and the American Society of Mechanical Engineers, the principal societies promoting the memorial, are to take part in the exercises, with their guests, the British Iron and Steel Institute, and the Verein Deutscher Eisenhuettenleute, of Germany.

After the exercises at the hall the procession will be formed and will march to Washington Square, where the statue will be presented by James C. Bayles to President Gallup, who will accept it on the part of the Park Department.

THE Expert Committee on the Brooklyn Bridge terminal facilities, composed of Samuel Spencer, President; Charles H. Buckholz, secretary, and Prof. George W. Plympton, have held preliminary meetings and organized. The plans submitted have been informally examined, and no others will be received, the date for their reception having expired on September 20. If any of those who have submitted plans desire to explain them, public hearings will be afforded. A report will be made at the November meeting of the trustees.

NOTES.

TORONTO, CAN., is reported to be suffering from a general breakdown of its water-works system.

THE officers and directors of the National Association of Builders met at the rooms of the Building Trades' Club, 20 East Twenty-first Street, New York, on the 22d inst., to make arrangements for the fifth annual convention of the organization, which will be held at New York on the second Tuesday in February.

CHIEF ENGINEER FTELEY of the new Aqueduct Commission, New York, has resolved to turn the water off from the big tunnel once more on October 1, so that a proper inspection may be made of the repairs on section 9, and if satisfactory, a consequent removal of the repair platform will be made. A leak has been discovered at shaft 24, but it is evidently of such modest dimensions that it can be fixed and the aqueduct placed in running order by October 15. There are now over 33 feet of water in the Central Park reservoirs, and water at the rate of 600,000,000 gallons daily is flowing to waste at the Croton dam.

AN English correspondent writes to the effect that electric lighting has just been adopted in a little village in the neighborhood of Nimes, which possesses only 465 inhabitants. Motive power is afforded by a water-fall. The dynamo is capable of a total supply of 1,600 candle power. The streets are lighted by 25 lamps of 16 candle power each.

AFTER hearing an argument on the subject by Erastus Wiman, the House Committee on Commerce, according to a Washington despatch, this week, ordered a favorable report to be made on Representative Covert's bill to authorize the construction of a tunnel under the waters of the bay of New York, between Middletown and New Utrecht, by the New Jersey and Staten Island Junction Railroad Company. The railroad tracks through the tunnel are to be open to all railroad companies desiring to use them, for a reasonable compensation.

OBITUARY.

ROBERT DUNBAR died in Buffalo on the 17th inst., aged 77 years. He was proprietor of the Eagle Iron Works, and was the father of the present system of grain elevators. His invention and improvement in elevators are known all over the world. He built most of those in Buffalo, also designing elevators at Liverpool and Hull, England, and Odessa, Russia, besides New York and other points in this country and Canada.

ARTHUR J. STACE, Professor of Civil Engineering at Notre Dame University, Indiana, died September 25. Professor Stace was born in Sussex, England, in 1838. He had been connected with the University of Notre Dame since 1860, and was one of the Commissioners to the Paris Exposition of 1889.

THE funeral of James Gallatin took place on the 19th inst. at his summer home in East Hampton, L. I., where he died suddenly of heart disease last week.

PERSONAL.

WILLIAM B. BURSON was recently appointed City Engineer of Streator, Ill.

M. R. SHERRED, civil engineer, of Troy, N. Y., has been appointed Assistant City Engineer of Peoria, Ill.

WILLIAM P. ROUNDS was recently appointed City Engineer and Superintendent of the Water-Works of La Salle, Ill., and Oliver Smith, formerly of Flint, Mich., one of his assistants.

MR. E. SHERMAN GOULD, leaves New York to-day, for Havana, Cuba, with a force of American workmen, to complete the Vento Water-Works, for the contractors, Messrs. Runkle, Smith & Co., 15 Wall Street.

ANGELO MYERS sent his resignation as a trustee of the Brooklyn Bridge, New York, to the Mayor's office on the 20th inst. Mr. Myers is a brother of Comptroller Myers, and it is said that he finds the duties of bridge trustee decidedly irksome. One cause assigned for Mr. Myer's resignation is that he is not in accord with the majority of the trustees as to the management of the bridge.

MEETINGS OF ENGINEERING SOCIETIES.

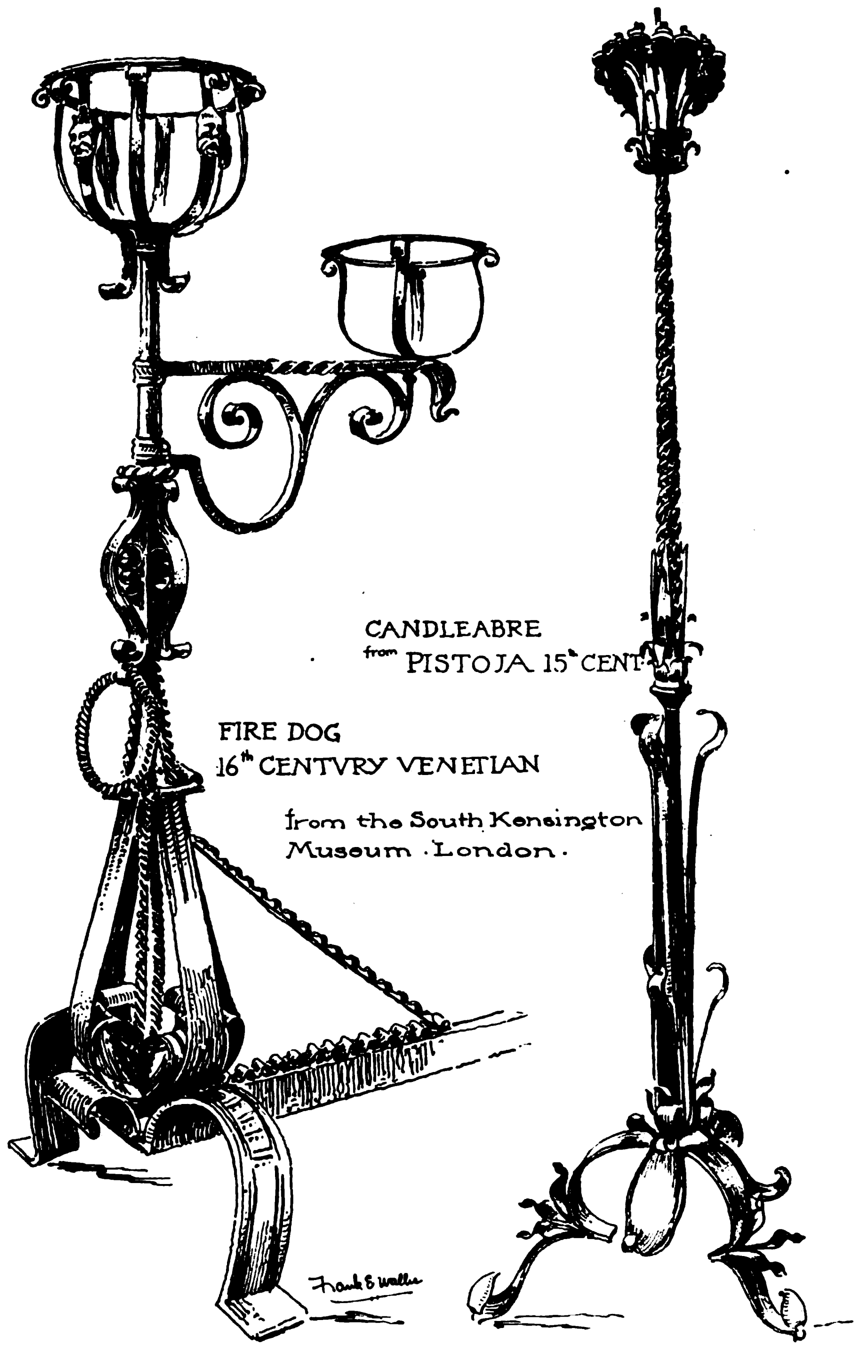
THE fifty-seventh meeting of the AMERICAN INSTITUTE OF MINING ENGINEERS will begin in New York City on Monday, September 29, 1890, at 2 P. M. All sessions will be held in Chickering Hall, 130 Fifth Avenue.

The AMERICAN SOCIETY OF CIVIL ENGINEERS holds its regular meetings on the first and third Wednesday in each month, at the House of the Society, 127 East Twenty-third Street, New York.

The BOSTON SOCIETY OF CIVIL ENGINEERS holds its regular meetings at the American House, Boston, at 7.30 P. M., on the third Wednesday in each month.

The WESTERN SOCIETY OF ENGINEERS holds its regular meetings at its hall, No. 67 Washington Street, Chicago, at 7.30 P. M., on the first Wednesday in each month.

The ENGINEERS' CLUB OF ST. LOUIS holds regular meetings in the club's room, Laclede Building, corner Fourth and Olive Streets, St. Louis, on the first and third Wednesdays in each month.



CANDELABRA AND FIRE-DOG FROM THE SOUTH KENSINGTON MUSEUM, LONDON.

The ENGINEERS' CLUB OF PHILADELPHIA holds regular meetings at the House of the Club, 1122 Girard Street, Philadelphia.

The ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA holds regular meetings on the third Tuesday in each month, at 7.30 P. M., at its rooms in the Penn Building, Pittsburg, Pa.

The ENGINEERS' CLUB OF CINCINNATI holds its regular meetings at 8 P. M. on the third Thursday of each month at the Club rooms, No. 24 West Fourth Street, Cincinnati.

The CIVIL ENGINEERS' CLUB OF CLEVELAND holds regular meetings on the second Tuesday of each month, at 8 P. M., in the Case Library Building, Cleveland. Semi-monthly meetings are held on the fourth Tuesday of the month.

The ENGINEERS' CLUB OF KANSAS CITY meets in Room 200, Baird Building, Kansas City, Mo., on the second Monday in each month.

The ENGINEERING ASSOCIATION OF THE SOUTHWEST holds regular meetings on the second Thursday evening of each month at 8 o'clock, at the Association headquarters, Nos. 63 and 64 Baxter Court, Nashville, Tenn.

The CIVIL ENGINEERS' SOCIETY OF ST. PAUL meets at St. Paul, Minn., on the first Monday in each month.

The MONTANA SOCIETY OF CIVIL ENGINEERS meets at Helena, Mont., at 7.30 P. M., on the third Saturday in each month.

The CIVIL ENGINEERS' ASSOCIATION OF KANSAS holds regular meetings on the first Wednesday in each month at Wichita, Kan.

The NEW ENGLAND WATER WORKS ASSOCIATION holds quarterly meetings in Boston at Young's Hotel.

The convention of the American Institute of Architects will be held in Washington, D. C., beginning on October 22, and continuing until the business has been completed. Papers on art, construction and kindred topics are solicited from the members. The titles of such papers should be forwarded to the committee of Arrangements by October 8, so they can be arranged for in the Order of Proceedings

THE NICARAGUA CANAL.

Telegraphic despatches received from San Juan del Norte (Greytown) announce the arrival there of the towing steamer "G. W. Jones" with the powerful steam dredge "Jules Dingler," which is one of the three largest dredges used on the Panama Canal, and has a record of excavating 237,000 cubic meters per month. The steamer also brought a large cargo of tools, machinery and supplies, which, with the dredge, is the first delivery on account of the important purchase made by the Nicaragua Canal Construction Company of the Slavin dredging plant. A large number of lighters and other property of great value are on their way from Colon, and the steamer "River Mersey" left that port yesterday with another of the large dredges, the "City of Paris," in tow, and another cargo of tools, machinery and supplies.

Satisfactory progress in railroad construction and other engineering work is also reported. The Medical Officer reports an excellent condition of health and entire freedom from epidemic and febrile diseases.

SKY SIGNS IN ENGLAND.

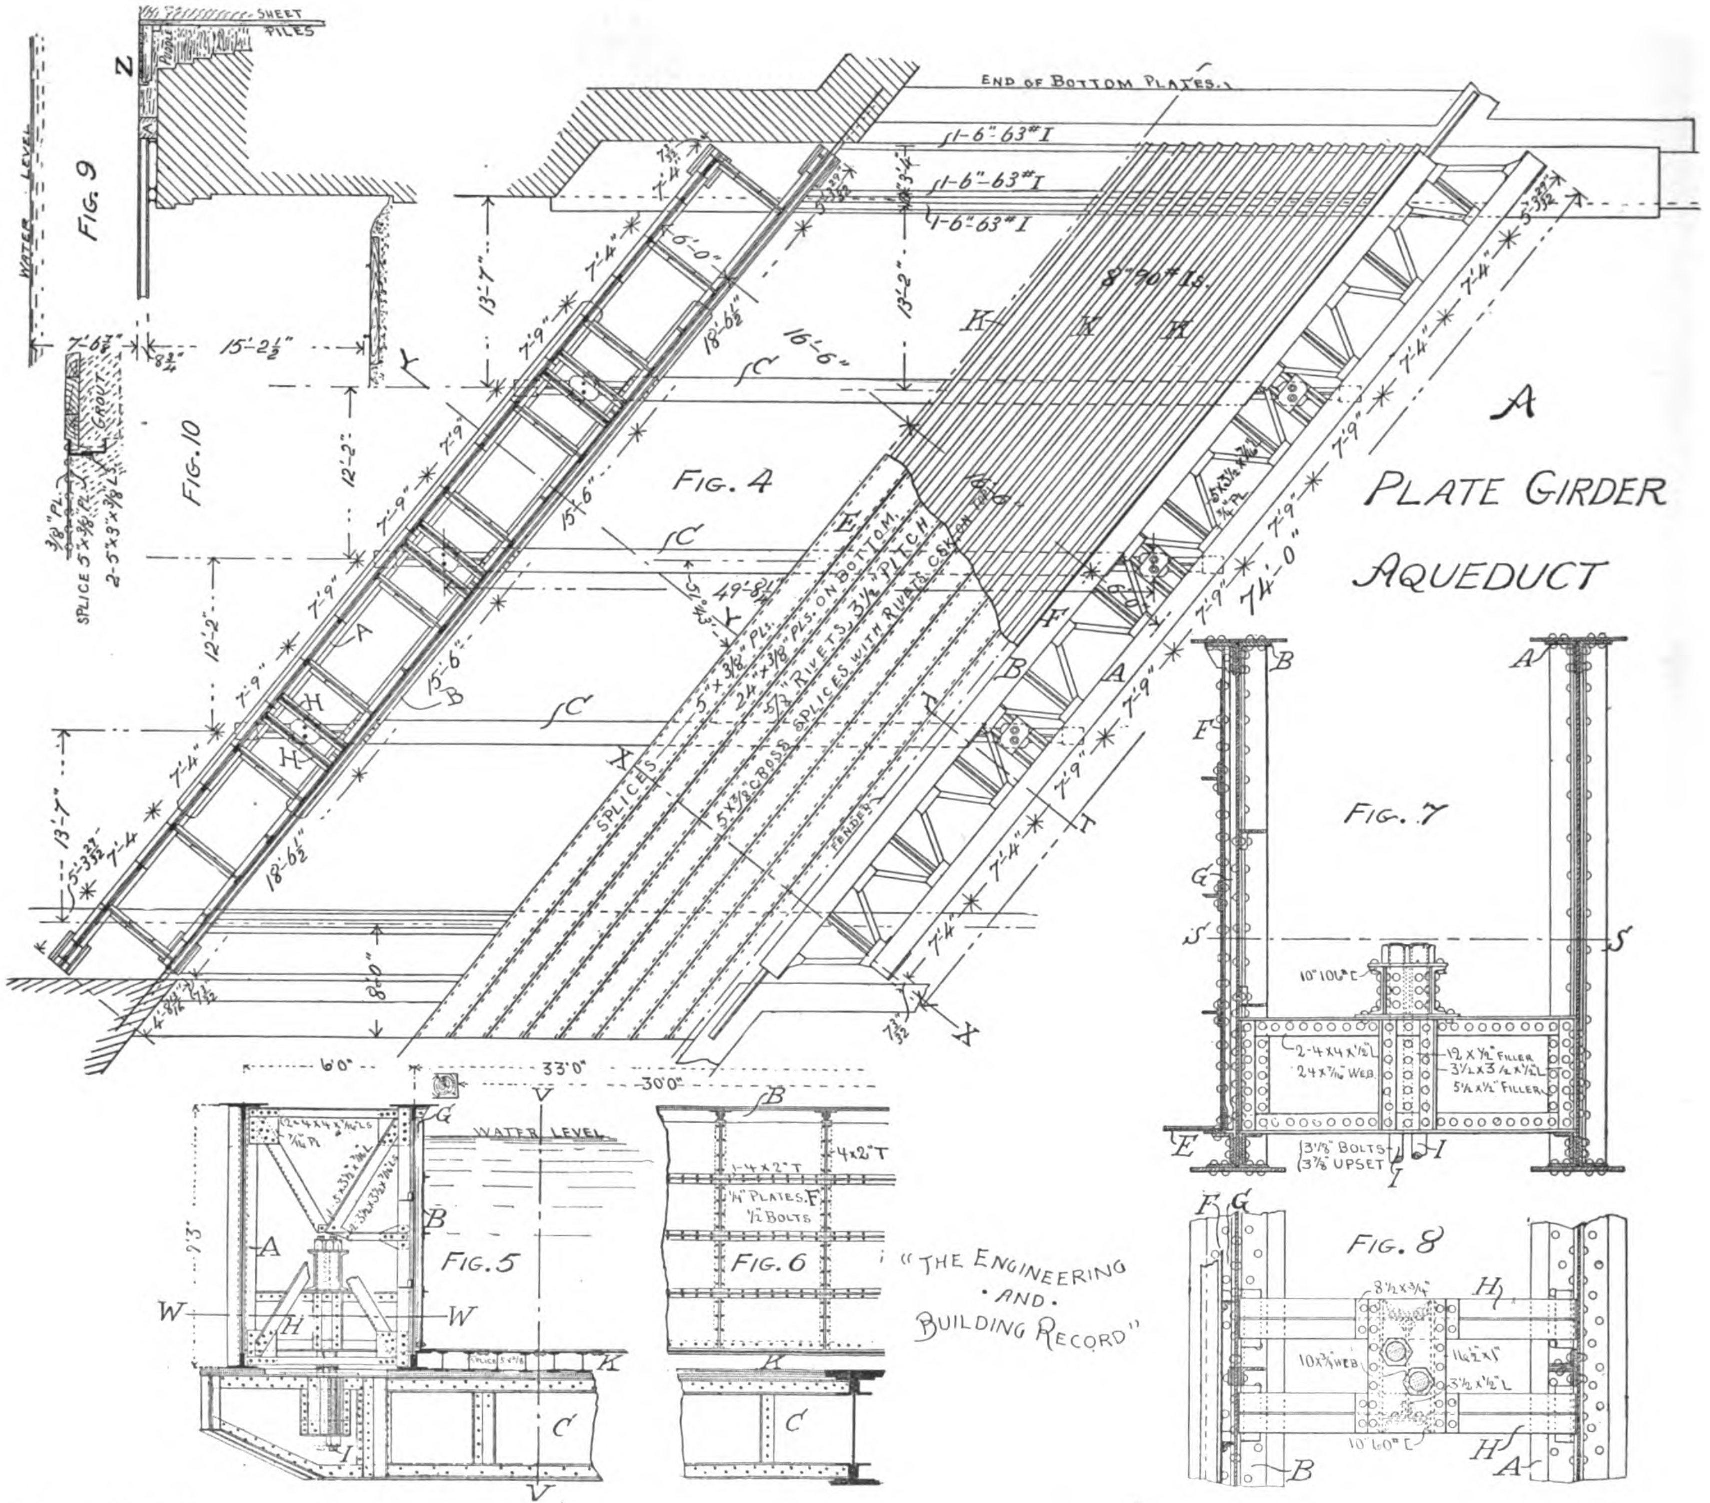
A LONDON correspondent writes that the question of sky signs is creating a great deal of discussion on the part of the public. The objections are so loud that a firm of provision merchants, Messrs. Hudson, who have recently erected a handsome building on Ludgate Hill, surmounting it by one of these sky signs at a cost of some £200, yielding to the pressure of public opinion, as enunciated in *The Times*, are taking down their sign after it has only been erected some fortnight to three weeks. The objection in the present instance arises from the fact that the sign is forced upon the vision of any individual standing at the foot of Fleet Street or Ludgate Hill who is looking up towards St. Paul's Cathedral. These signs, which are of patent construction, consist of a series of horizontal and perpendicular tubing of light construction properly stayed to the roof of the house. This frame work carries on the under side of its top cross member the series of large letters advertising the firm and its business. It is proposed to bring the matter under the notice of Parliament, with a view to obtaining legislation restricting the use of these large signs. The objectors take the ground that the height of buildings is restricted by legislation, and that legislation is called for and justifiable, inasmuch as the public has a right to uninterrupted study of the firmament.

A PLATE GIRDER AQUEDUCT.

The aqueduct illustrated herewith was built by the Pennsylvania Railroad Company to replace an old structure carrying the Delaware and Raritan Canal over two of its tracks at Trenton, N. J. In the new structure the length was increased to permit the laying of four tracks.

The original tunnel Fig. 1, was rather small for a train and engine. It was also a low spot in the grade and could not be properly drained. This tunnel was remodeled in 1876, when the arches were torn down to a point some 6 or 7 feet below the crown and the pier and abutments dressed off to give a width of 12 feet for each track, and a roof of beams and plate iron was substituted for the arches, Fig. 2.

In the two first structures the canal held its full width of 80 feet at water level, and the embankments were carried across the tracks, supported by the stone arches in the first case, and by the iron beams in the second.



To build the third and fourth tracks at this point, it became necessary either to make two more openings like those already described or to make a radical change of plan and dispense entirely with the intermediate piers. It was decided to adopt the latter course, and the present aqueduct, Fig. 3, is the result. The work was closely limited at almost all points, so that the solution of the problem was a little troublesome, but the aqueduct has been in service several months and is giving entire satisfaction. The leakage is very slight, the iron work being almost perfectly tight. There are two or three damp places on the masonry, but not enough water comes through to give any trouble.

The work of tearing out the old aqueduct was begun during the second week of December, 1889, and the new aqueduct was opened for traffic March 28, 1890. In this time the old abutments, containing over 3,000 cubic yards of masonry, were torn down, the excavation for the new abutments made, and about 2,500 cubic yards of new masonry built and the iron work put in place and riveted up. In addition to this a large amount of filling and puddling, etc., had to be done for the canal before the water could be turned into the level.

Figure 4 is a general plan of the aqueduct, the left side of it being shown in section at W W, Fig. 5, and a portion of the floor plates E being removed on the right side to show the floor joist, K K, etc.

Figure 5 is a vertical section of Y Y, Fig. 4.

Figure 6 is a section and elevation at V V, Fig. 5.

Figure 7 is an enlarged section and elevation at T T, Fig. 4.

Figure 8 is a horizontal section and plan at S S, Fig. 7.

Figure 9 is a section through the abutment and shows the connection between the aqueduct and the earth banks of the canal.

A, Fig. 9, is a brick wall, and Fig. 10 is an enlarged view of the detail at Z, Fig. 9.

Figure 11 is an outside elevation of the girder B.

Figure 12 is an elevation of the girder A.

Figure 13 shows a partial plan and elevation of floor beam C.

Figures 14 and 15 are sections at R R and Q Q, respectively, Fig. 13. The inside girders B B have lining plates F, Figs. 7 and 8, between which and their webs is a space G, filled with asphalt. The bottom plates E, and side plates F, are also thoroughly coated with asphalt on their wetted sides. The floor beams C C, etc., are suspended at each end by the hangers I I from the girders H H, etc., that distribute the load equally between the main girders A and B.

The total weight of iron in the aqueduct is 434,000 pounds. The four main girders weigh 153,000 pounds, and the cross girders weigh 25,200 pounds each.

The iron work was designed by William A. Pratt, Assistant Engineer Pennsylvania Railroad Company, and built by Cofrode and Saylor at their Pottstown shops.

The Pike's Peak rack railroad will probably be completed to the summit late this autumn.

FERROID, A NEW ARTIFICIAL STONE.

Ferroid, a new artificial stone, is made the subject of an interesting paper read a short time ago before the Civil Engineers' Club of Cleveland, by Herman Poole, and reprinted in the *Journal* of the Association of Engineering Societies.

Ferroid, as its name suggests, is like iron—in color, expansion and many other properties, and contains proportions of that metal varying from 25 to 33 per cent. It is a compound, partly chemical and partly mechanical, of the elements iron, sulphur and silicon, with more or less foreign matters; and from the union of these elements a material is obtained having some properties of each of its constituents, besides others possessed by neither.

It is mainly a super-saturated solution of iron in the sulphur, with the silica acting as a binder and hardener,

UTILIZING THE WATER POWER OF THE RHONE.

Colonel Turrettini, who has for many years been in the service of the municipality of Geneva, after having directed the works of the St. Gotthard Tunnel, has published a very interesting account of what has been done under his superintendence for the purpose of utilizing the waters of the Rhône, as they flow out of the Lake of Geneva, for motive power. According to the London *Times*, he begins by pointing out that it was not until 1708 that Geneva, which in the Roman period had an aqueduct that brought down water from the Savoy Mountains, was provided with a hydraulic motor for pumping up the water from the Rhone. A fresh machine was provided about half a century ago, while in 1880, these two being found insufficient, a steam pumping engine was found necessary. Preliminary investigations had already been made with the view of utilising the waters of the Rhône for motive power, and a company was formed for the purpose, but it was thought best that the work should be undertaken by the municipality itself, and in the autumn of 1882 the grand council granted it a concession. But before utilising the motive power of the Rhône it was necessary to regulate the level of the lake, and the authorities of Geneva determined to take this opportunity of settling a long-standing dispute as to the level of their lake. In the summer the waters rise high enough to incommode very much the occupiers of land upon the shore of the canton of Vaud, and the inhabitants of that canton have for more than a century asserted that the people of Geneva prevent the water of the lake running freely off because they obstruct the Rhône, while the argument of Geneva has been that the people of Vaud have only their own encroachments on the lake to thank for any damage they may have sustained. But, after a lengthy negotiation, the governing bodies of the two cantons came to an understanding, the cost of the works necessary to remedy the state of things complained of being put at about $460,000, a third of which was assumed by the Confederation, while the rest was paid by the cantons concerned. The works now completed have had the effect of regulating the depth of the lake and minimising the possibility of its overflowing its bank. The city of Geneva holds, therefore, the key of the lake, and the agreement come to between the cantons has already borne such good fruit that the Vaudais have not since had any reason to complain.

"The Engineering and Building Record"

It was not until September, 1883, that Colonel Turrettini laid his plans for the works to be executed in the Rhône itself before the municipality. The Rhône, as it passes through Geneva, is divided into two by an island covered with buildings, and Colonel Turrettini proposed that the right arm of the river should be reserved for running off the water, while the left arm, transformed into an industrial canal, was to conduct the water into a building to be constructed in the bed of the river, and in which would be placed, as they were required, twenty turbines with 4,400 net horse-power. The whole of this work is now done, except that only half the turbines are in use. The method of distributing the motive power gave rise to a good deal of discussion, but as Geneva does not possess any large manufactories, for which transmission by cable is suitable, the system of transmission by water under pressure was adopted, and the municipality decided to make two canalizations, one with low and the other with high pressure, the latter with an ascending force of 460 feet. The execution of the work was confided to a contractor, who agreed, in the event of the cost being below his estimate, to divide the profit with the municipality, while if the estimate was exceeded he was to lose his time, the municipality only defraying the actual expense incurred for labor, etc. The result was a saving of between $75,000 and $80,000. The enterprise was a very considerable one, for it was necessary to completely empty the two channels of the Rhône in succession. This was done in order to deepen the bed of the river, and give it a gentle slope from the mouth of the lake to the turbines. Opportunity was taken to construct upon the banks of the stream large sewers which run along the two banks of the lake and of the Rhône for a distance of more than three miles. These sewers, which cost about $480,000, empty into the Rhône some distance below the town, and thus prevent the water which is used by the inhabitants from being contaminated.

Several other works were also undertaken at the same time, including the dredging of the port, the reconstructing of a bridge over the Rhône, and the formation of a weir in the right channel of the river; while, in order to regulate the high pressure, it was necessary to form upon a hill about 2½ miles from the town a reservoir capable of holding 2,000,000 gallons of water. The practical result of the works has gone far beyond what the promoters anticipated, for at the end of last year there were 216 industrial motors, rated at 1,565 horse-power. All kinds of trade and industry make use of the water-power. The demands for power vary considerably, the minimum being a third of a horse-power, and the maximum up to the present 625 horse-power for an electric light company. The total cost of the work has been about $1,420,000, of which about $1,000,000 has been for the account of the municipality, while the gross return upon the sale of water in 1887 reached $115,000, or 150 per cent. more than it was nine years before. After deducting all the cost of maintenance, staff, interest, and paying off the capital invested, this leaves a clear profit of $27,500. The demands for more motive power are steadily increasing, and it is anticipated that in a few years' time all the turbines will be in use and that the municipality will have to fall back upon the reserves, which consist of an island some way down the Rhône, where a fresh motive force of 7,000 horse-power could easily be obtained and be transmitted to Geneva by electricity, the loss by waste en route being calculated at about 2,000 horse-power. But this would leave a margin of 5,000 for actual use, so that there is no fear of the supply running short, while the return upon the capital invested makes the enterprise a very profitable one for the municipality.

SEWER SPECIFICATIONS.

From the recent specifications of the city of Oakland Cal., for contracts to build about 3,600 feet of 2½ to 4 foot brick and concrete sewer, and about 4,300 feet of salt glazed vitrified pipe sewers and conduits, we make the subjoined extracts. For a copy of the specifications we are indebted to City Engineer T. W. Morgan.

All lumber that may be used in securing a foundation shall be black heart redwood.

Where the ground at bottom of sewer is firm and solid, clay, gravel, or hard pan, it will suffice to build the sewer upon. Where the ground is soft and yielding, or is of marsh mud, the soft material must be excavated to hard bottom and the cavity filled up to bottom of sewer with concrete, one part best Portland cement, three parts sand, six parts clean, hard, broken rock. In case this soft material is over 10 feet deep, then the sewer shall rest upon a pile and lumber foundation, piles not less than 10 inches in diameter at butt inside of the bark.

All excavation to be made in open trenches, batter not to exceed one-half inch to the foot.

All brick to be hard, well burned, well shaped, clear and ringing. Brick to be sprinkled, laid in cement mortar composed of one part fresh Portland cement, thoroughly *mixed dry* with two parts of clean, sharp sand before adding water. No mortar mixed over one hour to be used. Inside and outside of brickwork to be plastered with one to one cement mortar, inside smooth finished.

The concrete portions of sewer to be composed as follows: 1 part best fresh Portland cement, 2 parts clean, sharp sand, 4½ parts hard, clean, sharp, crushed rock. Sand and cement mixed dry three times turned, rock sprinkled as mixed, or the concrete may be mixed by latest improved concrete mixers. Concrete placed in layers of 6 inches, and well tamped.

In laying have bottom of pipe with full bearing on grade of ditch, bottom of ditch being cut out for each flange. Cement mortar placed in collar to bed spigot end for lower quarter of pipe, so that the bottom inside of pipe is flush, the joint around collar to be thoroughly filled with cement mortar, joint at end of collar covered at least one inch with mortar.

After a pipe is cemented it must have fine dirt filled and tamped thoroughly to half-way up the pipe before the next joint is put in.

All pipe sewer and conduits to have inside of joints cleared of projecting cement and rubbish by dragging along by a rope through the pipes, as they are laid, a sack stuffed with straw, fitting the pipe.

In filling trenches over sewer the earth is to be tamped in layers of six inches from the middle of the pipe to one foot above the pipe. The balance of trench may be filled in layers of one foot each to be well tamped, or by settling with water; provided, however, that the cement has had 24 hours to set before any settling is done by water.

THE ERYGMATOSCOPE.

THE Paris *Genie Civil* describes an instrument called the erygmatoscope, designed by M. G. Trouvé, for the examination of geological strata pierced by deep boring. The apparatus consists simply of a powerful electric incandescent lamp, inclosed in a cylindrical case, one of whose curved sides serves as a reflector, and the other, made of thick glass, permits the illumination of the bore hole. An elliptical mirror, set at an inclination of 45 degrees in the bottom of the case throws its images vertically upwards through the open top of the case to the observer who examines them with a powerful telescope. It is said that the apparatus works satisfactorily to a depth of 1,000 feet, and that the Portuguese Government has supplied it to its expedition that is exploring the shores of Mozambique.

A CONCRETE BRIDGE.

AT the freight station of Matzleinsdorf the Vienna Bureau of Works for Southern Austria has built an arch bridge of concrete to test the suitability of the Monier system (*i. e.*, the use of supplementary iron lattice bars) for the reconstruction of its numerous viaducts.

The arch rests on piers, is 32.8 feet span, 3.28 feet rise, 6 inches thick at the springing line and 8 inches at the key. The concrete, of Portland cement and Danube sand, 1 to 3, was rammed in layers, each 1½ inches thick.

The lattice work was buried in the concrete, and consisted of round bars ¼-inch and $\frac{11}{16}$-inch in diameter, laid 21½ inches apart, respectively, parallel and transverse to the axis of the arch, the latter extending in one length from abutment to abutment.

Fourteen days after the arch was finished the centering was removed. It was ballasted and a track of 31½-inch gauge was laid on it. Forty days later, after the temperature had fallen to eight degrees, the bridge was tested by groups of laborers and loaded cars, which carried 6,600 and 13,200 pounds on their two axles. A tender with three axles, each loaded with 20,300 pounds, and another with three axles loaded with 28,700 and 22,700 pounds, was also placed on the bridge, and the records made. Observations were made at nine points, three on each of three lines through the soffit parallel to the axis, one at the key and one half-way to the abutment each side. The maximum deflection was $\frac{1}{32}$-inch.

The *Revue Universelle des Mines et de la Metallurgie*, from which the above is taken, considers the results to justify the use of this construction.

THE Paris *Semaine des Constructeurs* announces the offer of three prizes of 15,000, 7,000 and 3,000 francs for the best designs of a palace for the Roumanian "chamber of deputies." The competition is open to the architects of all nations who should send their designs before November 15, 1890, to the Roumanian Legation at Bucharest.

PRESERVATION OF TIMBER.

AN interesting summary of recorded facts on timber preservation has been given by H. W. Reed, roadmaster of the Savannah, Florida and Western Railroad, as a report of the Roadmaster's Committee on the subject.

Mr. Reed states that there are four situations which require different properties in the preservatives used. These situations are:

1. Submersion in water, and subject in sea water to attack of the teredo navalis and other sea worms.
2. Exposure to alternate moisture and dryness.
3. Exposure to the atmosphere only.
4. Situated so as to be exposed to transverse strains.

Of the many preservative agents employed those of value may be resolved into several classes, viz.:

1. Those derived from the distillation at high temperature of vegetable tars, albuminous and oily substances.
2. Those having a mineral acid as a base.
3. Any modification or combination of the two foregoing classes.

Under the first head we have creosote, as the only known preservative capable of resisting for an indefinite time the attacks of the teredo and destruction of atmospheric germs and of leaving the structure of the timber in its normal condition and strength. Thus creosoting is the only process known that successfully meets *all* the requirements of a wood preservative, only one element, the expense, militating against it.

There is some question relative to the comparative value of coal tar creosote. The committee have been unable to learn of any experiments with it of sufficient duration to demonstrate its comparative value. But they are of the opinion that by observing the same rules in the use of the products obtained by distillation at high temperature we will arrive at about the same results as in the use of dead oil. If such proves to be the case we can expect to purchase creosote oil at much less that the present rate of one cent per pound.

Under the second head are the processes of: Kyanizing, treatment with corrosive sublimate; Burnettizing, the use of the chloride of zinc; Boucherie, the use of sulphate of copper.

The patents on these materials as applied to preserving timber have long since expired, thus we are at liberty to use any of them without royalty, provided we do not infringe upon various patented methods of their application.

With the salt at 50 cents per pound, the cost of Kyanizing is estimated at from 25 cents to 32 cents per tie. This process has been recommended for timber entirely protected from moisture (other than atmospheric moisture), but owing to the fact that corrosive sublimate is partially volatile at ordinary temperatures, is readily liquefied and is a deadly poison, invariably injuring the workmen engaged in preparing it, and that it is said to render the timber brittle, it is generally considered objectionable as a preservative for ordinary use.

Next in point of age is Burnettizing. Chloride of zinc, when used in large quantities as a solution, over three per cent. strong injures the elasticity and strength of wood seriously. The usual strength is 1.91 to 2 per cent. Another objection is that chloride of zinc is easily soluble in water, and therefore it is manifestly unfit for bridge timber; applied to cross-ties it serves a better purpose, as in that situation it has no transverse strain to resist, and is not readily washed out, but an objection occurs even here, as the ties are liable to crack and split under the rays of the sun.

The cost of this system is from 15 to 25 cents per tie. A report of a committee to the American Society of Civil Engineers, June, 1885, recommends Burnettizing as the best method for preserving cross-ties.

The Boucherie process, with sulphate of copper, has been tried extensively both in this country and in Europe. This process is a failure as against the teredo or other sea worms, and renders the wood very brittle, but as a protection to timber exposed to the atmosphere it seems to have been successful in a few cases and a particular failure in others.

Under the third heading is mentioned a modification of the Burnettizing process, which was patented by Mr. Wellhouse, and has since been extensively employed at several places, notably on the A. T. & S. F. R. R. This process consists, first, of an application of chloride of zinc with a little glue added, followed by a solution of tannin, "which it is claimed forms upon coming in contact with the glue small pellicles or films of insoluble artificial leather, which plug up the mouths of the sap ducts so as to prevent the zinc from washing out." This process has been employed only since 1879, and its merits are yet to be demonstrated.

While the committee find that creosoting is the most perfect, it is at the same time the most expensive method of timber preservation, and consequently it becomes desirable to form such a combination as will cheapen the process without decreasing the efficiency. This, it is believed, may be done for cross-ties by employing chloride of zinc (Burnettizing), which readily seeks the center or heart of timber, and does not readily return to the surface again, as the first material to be injected, and next to inject creosote as an outer covering or protection. By this means we obtain a valuable result at minimum cost. The creosote will overcome the tendency of the sulphate of zinc to wash out or volatilize, and will also neutralize the tendency of the timber to surface crack, as when the zinc alone is used, while the zinc will thoroughly protect the interior of the timber. Just how much the cost of creosoting can be reduced by this process only actual experiment can determine. It has been shown that Burnettized timber rots first on the outside, and creosote timber begins to decay on the inside. Thus the combination should be more perfect than either one alone.

Another process known as "Vulcanizing" has been recently introduced, and large claims are made for it.

In all works on the subject it is insisted that open grained or sappy, or thoroughly seasoned timber alone should be used, for the reason that such timber absorbs the preservative solution after the sap is partially removed by seasoning.

Many processes of applying preservative agents have been resorted to, from the ordinary paint brush through the various stages of steeping, vital suction and application by hydraulic pressure, to the more perfect means of exhaust and pressure within a closed iron cylinder. This latter method excludes sulphate of copper and corrosive sublimate, which have a deleterious effect on iron. Thus Kyanizing has to be carried on by the steeping process, the timber being placed in vats or tanks, thus rendering this process very tedious. Chloride of zinc and creosote may be applied in a closed cylinder successfully.

Another method of treating timber is by charring it within closed iron cylinders; this process is patented, and is yet on trial. It seems to possess merits of coagulating the albumen rapidly and of placing another exterior barrier against destructive action, as it is well known that charring the outside of timber without the aid of other treatment will materially increase its life. This method, however, is not recommended, as the steaming process seems to possess all the merits of simplicity and efficiency.

THE EFFECT OF FREEZING UPON IMPURITIES CONTAINED IN WATER.

REGARDING the effect of freezing upon impurities in water the Massachusetts Board of Health has published experiments, as stated by *Public Health*, with 76 samples of water and 336 samples of ice from 58 localities In ice from polluted sources compared with water from the same, the experiments showed: (1) That in the ice the color and salt had been removed. (2) That all but 13 per cent. of the other impurities of the water, as shown by chemical analysis, had been removed. (3) The number of bacteria in the cubic centimeter were: For snow (one sample), 1,246; for clear ice (part of the same cake as above), 6; for clear ice from an unpolluted source, 0. (4) The average of 12 samples from the most polluted sources, 138. The number of bacteria varied much in different parts of the same cake.

From the examinations which have been made, it appears probable that when ice first forms in the surface of a pond or river, a considerable part of the impurity in the water near the surface is entangled in the first inch or less in depth, and that the ice which forms below this first inch contains but a very small percentage of the impurities of the water. If snow falls upon the thin ice, causing it to sink, so that the water from below saturates the snow, it will freeze without purification; or if rain falls upon the snow and freezes, the ice thus formed contains the impurities of the snow and of the rain water, and of whatever else may have settled out of the air. The method often pursued, of flooding the ice of a pond or river by cutting holes through it, gives a layer of ice as impure as the water of which it is formed.

The purifying effect of freezing is greater upon substances in solution than upon those in suspension. This is confirmed by the fact that a large part of the organic matter, one-half or three-quarters, and sometimes more than is found in good ice, is of particles in suspension, and is readily removed by filter paper.

From the average of all the water and ice used for ice supplies, which they have examined, they find: The organic impurities of snow ice (the sum of the ammonias) = 69 per cent. of the impurities of the water. The organic impurities of all the ice (except snow ice) = 12 per cent. of the impurities of the water. The organic impurities of clear ice = 6 per cent. of the impurities of the water. The color of waters was removed by freezing. The salt of the waters was nearly removed by freezing.

Of bacteria there were 81 per cent. as many in snow ice as in the waters, 10 per cent. as many in all other ice as in the waters, 2 per cent. as many in clear ice as in the waters.

The results obtained lead to the conclusions: That while clear ice from polluted sources may contain so small a percentage of the impurities of the source that it may not be regarded as injurious to the health, the snow ice, or any other, however clear, which may have been obtained by flooding, is likely to contain so large a percentage of the impurities of the source, and with these impurities some of the disease germs which may be in the source, that the board feels bound to warn the public against using ice for domestic purposes that is obtained from a source polluted by sewage beyond that which would be allowable in a drinking water, stream or pond, and that in general it is much safer to use for drinking water, and for placing in contact with food that portion of the ice that is clear.

RIVER SLUICES.

AT the recent meeting of the British Association for the Advancement of Science, F. G. M. Stoney read a paper on "The Construction of Sluices for Rivers." This paper possesses special interest from the fact that Mr. Stoney's sluices are playing an important part in the design of the Manchester Ship Canal.

Mr. Stoney pointed out that in Indian irrigation many attempts have been made to work, or render more workable, sluices for the supply of water to canals, and while some experimenters confined their attention to finding means of overcoming great resistance with greater power, others have more properly sought to devise means for eliminating resistance to motion in sluices, rather than overcoming that resistance. This latter he held is the true direction to work in, and has eventually conduced to the best results. Several forms of the throttle valve have been tried on irrigation sluices, and have not succeeded. The principle is not very suitable for solid bodies like water, because what may be nicely balanced in static pressure may not be at all balanced when eddies and reflex forces are generated under high velocities. Such sluices have also failed mechanically, because of the too great concentration of load on pivots; moreover these pivots may be subject to the action of rust and grit. The ordinary sliding doors are subject to an amount of friction which precludes their useful application to such large openings as are now generally required. Equilibrium sluices have been made by arranging two outlets directly opposite each other, and the two doors closing the outlets so constructed as to form one plug (as it were) filling the space. The water pressure on one door being equal and opposite to that on the other door, the pair were in equilibrium. Here again was a very promising scheme, but the heavy bodies of water directly impinging would quite prevent this appliance being used in great sizes.

Another form of equilibrium sluice, specially designed for canal locks, was made by stopping a horizontal circular orifice by a cylinder. This cylinder had neither top nor bottom. Its lower edge, neatly faced in the lathe, rested on a suitably prepared face round the valve seat, and the top of the cylinder stood above water level. In this way the column of water was completely removed from above the sluice orifice, and the surrounding water simply tended to compress the cylinder, but not to prevent its vertical motion. The weight of the cylinder was balanced, and lifting it one-fourth of its diameter gave the full area of the sluice-way. Many of these sluices were made, and proved very useful. They were abandoned by Mr. Stoney chiefly for two faults: they pumped large quantities of air into the culverts, and they could not be applied to direct openings for scouring purposes. The most successful sluice for almost any situation is the sluice on free rollers. In this case there is not any sliding friction. The sluice door carried its load of water pressure on free rollers, the motion being similar to that of the drawbridges on free rollers, and to that of observatory cupolas mounted in a like manner. There is, however, one marked difference as to the planes of motion. The ordinary application of free rollers was on horizontal planes; in the sluices it is on vertical planes, which was one of the primary difficulties in the way. But no doubt the bare idea of introducing free rollers between the sluice door and the sluice frame, apparently precluding the possibility of a water-tight joint, was the real stumbling block to be got over. Sluices on free rollers are now constructed to any required size, and to be easily workable under great pressure, by one man, without hydraulic power. They have proved very reliable during years of test, and the wear and tear is hardly noticeable, chiefly because of the absence of resistance.

These sluices are made to suit single, double, or alternate pressures and they are made water-tight in various ways, according to the degree required, from absolutely tight to sluices purposely not made tight. These sluices can be usefully applied to the purposes of increasing water power without increased risk of flooding the country; on the contrary, they have proved most successful in preventing floods. They can also be applied to the main stream of navigable rivers, as in the plan now sanctioned by Parliament for Richmond, England, in which three sluice gates, each 70 feet clear span, are used to hold up water to half-tide, and at that period or level of water the gates are quickly raised some 23 feet above Trinity high-water mark, to allow of barges and steamers sailing under. A new element has been introduced into these sluices, by which during the upper part of the lifting process the gates automatically turn over on their flats and disappear in the overhead bridges.

ENGINEER COOLEY AND THE CHICAGO DRAINAGE BOARD.

It is gratifying to see such sensible comments as appear in the Chicago *Herald* in its reference to the recent conduct of certain members of the Drainage Board and their treatment of their chief engineer. The *Herald* says:

> "Probably one of the most absurd demonstrations of egotism that this community has been favored with recently is that of which the Drainage Board is guilty in its treatment of Chief Engineer Cooley. Not one of the commissioners is a scientific man. Not one of them knows anything about the engineering problems involved in the work about to be undertaken. Yet nearly all of them have assumed an attitude toward the chief engineer that is offensive, dictatorial and impertinent
>
> "It is morally certain that if Chicago is to be drained these commissioners will be compelled to depend upon the advice of some such man as Mr. Cooley. They may imagine that they know all about it and they may be disposed to go off recklessly on guesses and theories of their own, but the people who must foot the bills would prefer to be guided by an expert who knows his business.
>
> "The commissioners should do everything in their power to assist the engineer in his preliminary surveys and in his estimates. He should not be handicapped or bullyragged in any manner. If politics has crept into the board, let the man responsible for its introduction be rebuked. If conceit has taken possession of any member, let him be admonished. If there is a disposition to snarl and to carp, let it be discouraged.
>
> "These commissioners have an important duty, but they are not expected to work miracles. It is known that not one of them is an expert. It is known that they are all dependent upon others for scientific knowledge as to the problem in hand. They will, therefore, stand much better in this community if they will sensibly and modestly defer to the man whom they and the people must look to for facts and figures."

Such advice is too often needed by commissioners in other places.

ANCIENT MORTAR.

A sample of mortar, says *Industries*, taken from a building in the neighborhood of Ober-Florstadt, erected towards the close of the third century, had the following composition: Silica, 78.39; alumina, 7.35; carbonate of lime, 8.41; sulphate of lime, 0.32; other lime salts, 0.97; carbonate of magnesia, 0.42; combined water, 2.76; moisture, 1.32. Only traces of alkalies and chlorine were present. The sample is chiefly remarkable for the considerable quantity of alumina it contains.

LIME *VS.* CEMENT MORTAR.

Prof. Ira O. Baker contributed to the last volume of Transactions of the Illinois Society of Engineers and Surveyors some notes on the use of cement mortar, from which we take the following:

Common lime is made by heating nearly pure carbonate of lime—limestone or marble—sufficiently to drive off the carbonic acid. Common lime mortar hardens by absorbing from the atmosphere the carbonic acid which was driven off in making the lime. It will never harden under water, or when excluded from the air.

Hydraulic lime is made by exposing limestone containing from 10 to 20 per cent. of clay to a comparatively long-continued and high heat, which drives off the carbonic acid, and causes a chemical combination to take place between the remaining elements. The common lime in the compound causes the whole mass to slake when exposed to water or moist air, while the compounds of clay with the lime prevent its slaking freely and cause it to set, to a moderate extent, under water.

Hydraulic cement is made by submitting a limestone containing about 20 per cent. of clay to a long-continued and very high heat, which drives off the carbonic, and causes all, or nearly all, of the clay to unite chemically with the lime. As there is little or no free lime in the residue, it will not slake on the addition of water, and hence must be reduced to powder by grinding between ordinary millstones.

There are two classes of hydraulic cement—Portland and Rosendale. The latter is frequently called "natural," "American," "domestic," and "Roman"—all of which are misappropriate. Portland cement is heavy, slow-setting, and has great ultimate strength. Rosendale is less heavy, sets more quickly, and has less ultimate strength than Portland. Roughly speaking, Rosendale weighs about two-thirds as much as Portland, sets in one-tenth of the time, and attains to about half the ultimate strength. There is a great variety of brands of each class, which differ from each other in minor particulars.

Nearly all masonry is laid in lime mortar, in which case the mortar is the weakest link, both in strength and in durability. This is particularly true of buildings. When a brick building burns, it is noticed that the masonry tumbles down as rapidly as the wood burns up. If well built with good mortar the walls would stand intact even though the interior and roof did burn. Again, nearly all brick buildings, after having stood ten or fifteen years, require a considerable amount of pointing up, particularly in damp places and against chimneys. The strength and durability of the masonry could be greatly increased by replacing even part of the lime with cement. The mortar for the "ordinary brick-work" of the United States public buildings is composed of "one-fourth cement, one-half sand, and one-fourth lime." Many private builders reinforce lime mortar by the addition of hydraulic cement, and many railroads employ cement mortar in all masonry structures, and cement mortar is generally used for sewers, arches, and important masonry constructions; but it is neverthelesss true that altogether too much lime mortar is used. Under most favorable circumstances as to exposure to the atmosphere, lime mortar will attain a maximum strength of about 50 pounds per square inch, as compared with a possible 300 for Rosendale and 500 for Portland.

The addition of cement to lime mortar adds to its strength—the strength of the resulting mortar being intermediate to the strength of the two separately. However, it is not certain that it is true economy to mix lime and cement. As far as strength is concerned, the lime, under favorable circumstances, is but little better than an equal volume of sand, and, under water, in damp places, or in thick walls, it is not as good. Lime mortar taken from the walls of ancient buildings has been found to be only 50 to 60 per cent. saturated with carbonic acid after nearly 2,000 years of exposure. Lime mortar 2,000 years old has been found in subterranean vaults in exactly the condition, except for a thin crust on top, of freshly-mixed mortar.

The strength and durability are unquestionably mainly dependent upon the mortar, and it is highly illogical to insist upon a high quality of stone or brick, or of stone instead of brick, and then use common lime mortar. Experiments show that an increase of 50 per cent. in the strength of the brick shows no appreciable effect on the strength of the masonry, and that the substitution of a Portland mortar for a lime mortar adds 70 per cent. to the strength of the masonry; and also that the substitution of a Rosendale mortar for one of lime adds 50 to 60 per cent. Probably the difference in durability between cement motar and lime mortar is considerably greater than their difference in strength.

If cement is to be used, it then becomes a question whether Portland or Rosendale should be preferred. If great ultimate strength is required, then Portland cement must be employed; but if a quick-setting mortar is desired, then Rosendale cement must be employed. Unless a quick-setting mortar is required there is a decided advantage in using Portland, for, as it hardens more slowly, it is not so liable to set before reaching its place in the wall. This is an important item, since with a quick-setting cement any slight delay might necessitate the throwing away of a box of mortar, or the removal of a stone to scrape out the partially set mortar.

It is sometimes very desirable to have a cement which will set more quickly than Portland, and finally attain a greater strength than Rosendale. Under such circumstances a mixture of Portland and Rosendale can be used. Such mortar sets about as quickly as if made with Rosendale cement only, and acquires great subsequent strength, due to the Portland cement contained in it. The strength of the mixed mortar is almost exactly a mean between that of the two mortars separately.

If the choice of the cement is not determined by any of the preceding conditions, the question then becomes one of relative strengths and relative prices. For example, an examination of a table of the strength of cement mortars will show that at the end of a month the strength of a neat Rosendale mortar is equal to that of a 1 to 1½ Portland mortar, a 1 to 1 Rosendale is equal to 1 to 3 Portland, and a 1 to 2 Rosendale is equal to a 1 to 5 Portland. The cost per cubic yard of the last two mortars will be about as follows:

Rosendale 1 to 2.		Portland 1 to 5.	
Cement (720 lbs.), 2.40 bbls. at $1	$2.40	Cement (425 lbs.), 1 14 bbls. at $3	$3.42
Sand, 0.84 cu. yd. at $0.40	.33	Sand, 0.99 cu. yd. at $0.40	.40
Labor	.50	Labor	.50
Total cost of cu. yd.	$3.23	Total cost of cu. yd.	$4 32

This shows, that, under these conditions, the Rosendale, strength for strength, is the more economical.

In conclusion, Professor Baker gave the following fact, by means of which a mortar may be made impervious to water. Mortar may be made practically non-absorbent by the addition of alum and potash soap. One per cent., by weight, of powdered alum, is added to the dry cement and sand, and thoroughly mixed, and about one per cent. of any potash soap (ordinary soft soap made from wood ashes is very good) is dissolved in the water used to mix the mortar. The alum and soap combine and form compounds of alumina and the fatty acids, which are insoluble in water. These compounds are not acted upon by the carbonic acid of the air, and add considerably to the early strength of the mortar, and somewhat to its ultimate strength. With lime mortar the alum and soap has a slight disadvantage, in that the compounds which render the mortar impervious to water also prevent the air from coming in contact with the lime, and consequently prevent the setting of the mortar. On the other hand, the alum and soap compounds add considerably to both the early and ultimate strength of the mortar. This mixture could be advantageously used in the mortar of outside walls, for masonry in wet places, for pointing mortar, for the plastering of cellar and basement walls, for lining cisterns, etc. The efficiency of the alum and soap compounds is shown by the fact that the walls of the Croton reservoir, in Central Park, New York City, were rendered impervious by simply washing them four times alternately with the alum and the soap solutions. Before being coated the walls allowed the water to pass freely. Four coatings—two pairs—made a common brick absolutely impervious under a 40-foot head of water.

The use of the alum and soap as above would in all cases greatly diminish, and in most cases entirely prevent, efflorescence or "whitewash," which so frequently disfigures brick walls.

The London *Engineer* says, that according to a report from Dacca, the great iron bridge at Tongi, India, which cost the late Rajah Kali Narayan Rai Bahadur an immense sum, has been clean washed away by a flood.

EARLY HISTORY OF NEW YORK'S WATER SUPPLIES.

IN connection with the completion of the New Croton Aqueduct, conveying water to the city of New York, it is of interest to recall some of the early facts relating to the city's water supplies, as given in one of the daily newspapers.

It was not long after the early settlement of New York that the want of a sufficient water supply was felt. Wells were at first the only source of supply. Up to 1658 there were no public wells, the inhabitants supplying themselves from private wells on their own premises. In 1658 a public well was sunk in front of the old fort. Nineteen years later six additional wells were ordered, the inhabitants of the streets where they were made defraying the expense. This order went out in the following shape:

One well opposite Roelof Jansen's, the butcher; one in Broadway, opposite Van Dyck's; one in the street, opposite Derick Smith's; one in the street, opposite John Cavalier's; one in the yard of the City Hall; one in the street, opposite Cornelius Von Boroum's.

Seven more public wells were ordered in 1687, and the city government undertook to pay one-half the expense. No person could use a well until he had contributed toward the cost of it.

It was a great event in 1750 when pumps came into use. Afterward a general act was passed to enable the city to raise a tax for the construction and repairing of the public wells and pumps.

Some of the wealthier inhabitants at this time preferred to send to the suburbs for their water supply. The water in the wells was not good. They sent out to the Fresh-Water Spring, known at that time and long afterward as the "Tea-Water Spring." Just before the Revolution the vicinity of the spring, now the junction of Park Row and Roosevelt Street, became a popular and fashionable resort, where various beverages, mixed with pure spring water, could be obtained.

A pump was put up over the spring and a sort of park was laid out around it. The people called this resort "The Tea-Water Pump Garden." Water was bartered for like any other commodity. Venders sold it by contract, or at a cent or a cent and a-half a pail. Knapp's tea water, which was drawn from a spring near the old White Fork, at Tenth Avenue, near Fourteenth Street, gave a good living to a great many men. Mr. Sweeny, the founder of Sweeny's Hotel, is said to have obtained his start in life as a vender of water.

A company, styled the "New York Manhattan Water-Works," was incorporated in 1799 for the purpose of supplying the city with pure and wholesome water. This was the year after the yellow fever had ravaged through the city. But the Manhattan Company seemed more interested in banking money than in furnishing pure water. The company's works consisted of a well in Cross Street, two steam engines, a reservoir on Chambers Street, and a couple of small wooden reservoirs.

Another of these old wells—the one in lower Wall Street—inspired Samuel Woodworth to write his famous poem, "The Old Oaken Bucket."

To Christopher Colles, however, is given the credit of having suggested, in 1774 the scheme afterward adopted by the Manhattan Company, that of digging large wells and pumping water from them into reservoirs. Colles even looked so far ahead as to see the advantages of communication uniting the great lakes and the Atlantic Ocean. In pursuance of Colles' plan a spacious reservoir was built on Broadway, between Pearl and White Streets. But these reservoirs and wells did not succeed in giving New York a sufficient water supply. In 1819 Robert Macomb asked permission to furnish the city with water. No positive action was taken, however, until 1829, when it was resolved by the Board of Aldermen to establish a well and reservoir in Fourteenth Street. There were at the time 40 public cisterns in the city.

Half a dozen companies were incorporated in succession, having the view of furnishing pure water to the city, but they met with no success. In 1830, an iron tank 43 feet in diameter, 20 feet high and containing 305,422 gallons of water was completed at Thirteenth Street and Fourth Avenue.

Francis B. Phelp's memorial of May 17, 1830, was the first definite proposal for the introduction of Croton water into the city. The same year it became necessary to build 16 more cisterns. Colonel De Witt Clinton favored the Croton project, and in 1834 the Common Council obtained from the Legislature a law authorizing a loan of $2,500,000 to create a stock called the "Water Stock of the City of New York." Under Chief Engineer D. B. Douglas and four district engineers the work on the Croton Aqueduct was begun in the spring of 1837. In 1839, the Legislature authorized the erection of High Bridge, on which to convey the Croton over the Harlem River. The total cost of the aqueduct was $11,452,619.61.

Extensive preparations to celebrate the completion of the aqueduct were begun by the Fire Department, and the city appropriated $2,000 for the expense.

At sunrise on the day of the celebration 100 guns were fired and all the church and public bells were rung At 9 A. M., in front of the City Hall, Mayor Morris presented a banner to the Fire Department. In the procession there were ten divisions, and over two hours were taken in passing a given point.

High Bridge was finished in 1848, and ten years later the large reservoir in Central Park was begun. It was completed in 1862. The two 36-inch pipes crossing High Bridge were replaced in 1861 by a large 7½-foot iron pipe, equal to the full capacity of the aqueduct. The high-pressure works at High Bridge were made available in 1870. The storage at Boyd's Corner was completed in 1873. The Carmel Reservoir became available in 1878. Up to 1879 the total expense for everything connected with the water supply had been $35,820,081.46.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

THE USE OF CLAY IN MACADAM ROADS.

NEW YORK, September 20, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: A controversy is going on in Union County, New Jersey, about the wisdom of permitting the use of 2 inches of clay over the Telford foundation, "for the purpose of forming a bond or cushion for the first overlying course of macadam." In a published communication defending this practice, one of the Commissioners says:

"Clay, as used in the Union County roads, is something over and above anything and everything called for in the original contracts of last year, and does not in any way or to any degree lessen or modify the quantity, quality or number of courses of stone or binding of screenings and stone dust used in the construction of the roads. Nor is the contractor allowed anything in measurement for the 2 inches or clay. He is required to furnish so many inches of stone, in such and such courses without regard to the clay, and entirely independent of it. It is simply an additional requirement made of the contractor without additional cost to the county. Such use of clay prevails and has prevailed for the past 15 or 20 years in England and Scotland, the home of Macadam and Telford roads, to the entire satisfaction and comfort of the public, and without detriment to the roads. It has the sanction of such eminent road builders as D. C. Proudfoot and David Stratton, road surveyors, etc., for the city and county of Edinburgh. The clay thus used forms a cushion or bed, and instead of filling up and destroying the drainage, as claimed by some, actually prevents this very thing occurring by arresting and holding the stone dust and screenings, which, from experience, we know will sift through the larger courses and interfere, more or less, according to the quantity used, with the proper drainage of the road. Furthermore, it gives a Telford road the elasticity so justly claimed for the macadam, and adds to its comfort and life."

Is it a fact that the practice of the best road builders abroad has so far departed from what has been for years the recognized standard? C. E.

[The contractor can well afford to add clay to a macadam road without extra charge, as its presence greatly reduces the cost of rolling. We would, however, be pleased to hear from any of our readers on the subject.]

LARGE SIZE VITRIFIED PIPE FOR SEWERS.

SPRINGFIELD, ILL., September 15, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: I was interested in reading the letter of Col. George E Waring in your issue of September 13, under the head of "Vitrified Pipe for Sewers." I can hardly agree with him in the assertion that the material is not a safe one to use in a larger diameter than 15 inches, and would not hesitate to adopt a diameter of 20, or even 22, inches, if good sound vitrified pipe is used, especially if laid in a clay subsoil and care is taken in laying the pipe on a solid bed. I think the failure in the large pipe is due to insufficient excavation under the sockets.

I fully agree with him that in providing specifications for sewers 3 feet in diameter, two rows of brick is a waste of material, and would not only construct sewers of 3 feet caliber with a single row, but would not hesitate to construct them up to a diameter of 4, or even 5 feet, if good material is used. In this city, up to 1887, sewers of 3 feet and over were constructed with two rows of brick, and from 5 to 7 courses in the invert, laid dry. I succeeded in securing the adoption of a single ring with the invert laid in cement mortar, saving at least 40 per cent. in the cost, and securing a far better job than when constructed with a double ring. It is of vital importance in sewer construction that the very best material should be used, and thorough construction secured. With these there is not the least danger in construction up to a diameter of 5 feet, and in deep excavation and clay, or hardpan subsoil, a very much larger diameter might with perfect safety be constructed with a single ring. W. D. CLARK.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department.* Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

HOW TO KILL GRASS AND WEEDS IN GUTTERS AND SIDEWALKS.

D. F. SNOW, New York, writes: "In answer to John W. Howard's inquiry in the current number of THE ENGINEERING AND BUILDING RECORD as to 'the best and most appropriate method for killing grass and weeds that grow up in our gutters and sidewalks,' I would say that I had no difficulty in keeping the grass and weeds out of the graveled paths and roadways of a country place, owned and occupied by myself, by the simple application of salt (chloride of sodium) in its dry state. I should say that a strong brine made of the same material and applied by a sprinkler would be just as effectual."

ADDRESS OF BUILDING MOVER.

H. E. SMITH, of York, Pa., writes: "Will you please give me the address of a firm, or firms, who make a specialty of raising brick buildings from their foundations?"

[We would refer our correspondent to the following: Sam. E. Goodwin, 517 East Seventeenth Street, and T. B. Brown, 365 South Street, New York City.

Isaac Blair & Co., 444 Harrison Avenue; J. Cavanagh & Son, 473 Dorchester Avenue; and John Soley, 35 Hawley Street, Boston, Mass.

W. R. & G. R. Cavanagh, 207 E Street, South Boston, Mass. A. M. Richards, 39 Lexington Avenue, Charleston, Mass.]

BOOKS ON BREWERY DESIGN AND CONSTRUCTION.

"J. A. F.," Boston, Mass., writes: "Can you give me the titles and publishers of any reliable American or foreign works on the planning and construction of modern breweries (especially those for brewing lager beer), and the arrangement of their fixtures and machinery?"

[After extended inquiry it would seem that the literature of the subject referred to by our correspondent is rather scant. Messrs. E & F. N. Spon, of New York, are the publishers of a book entitled "Breweries and Maltings: Their Arrangement, Construction, Machinery and Plant," by George Scammell. Second edition, revised and enlarged and partly rewritten by F. Colyer; 178 pages, with 20 plates; London, 1880. Price, $6. This might meet J. A. F.'s requirements.]

BOOK NOTICES.

PURVES' TABLES OF BOILER PRESSURES. John Brown & Co., Ltd; Sheffield, England.

These tables, which are issued in neat and convenient form, give Lloyd's working pressures for steel boilers, and of furnaces under Board of Trade and Lloyd's rules. The pressures given are for flat plates with different methods of staying and various pitches of stays, for boilers with cylindrical shells, and for circular and patent ribbed furnaces. Various rules are also given for determining the safe working pressures. The value and convenience of the tables are at once apparent, and they will commend themselves favorably to engineers.

ACCORDING to our Italian contemporary, *Progresso*, articles of iron can be protected against rust by sinking them near the negative pole of an electric bath composed of 10 liters of water, 50 grammes of chloride of manganese, and 200 grammes of nitrate of ammonia. Under the influence of the current the bath deposits on the articles a film of metallic manganese which prevents them from rusting.

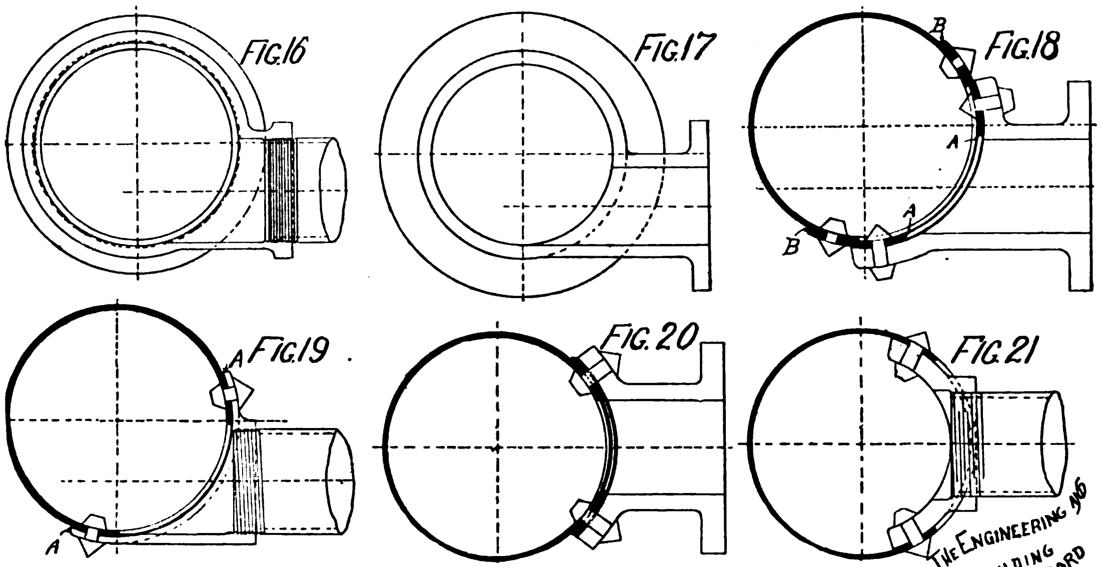
DOMESTIC ENGINEERING
PLUMBING HEATING LIGHTING & VENTILATION

ATTACHMENT OF NOZZLES TO STEAM DRUMS.

THE attachment of nozzles to steam drums is the subject of the third of the series of articles in the August number of *The Locomotive*, alluded to in previous issues. We quote as follows:

"To the best of our knowledge we have never seen the nozzles of a large steam drum, that is, those forming the connection between the boilers and drum, put on as they should be. This seems to be rather a sweeping statement, and may seem to reflect upon the abilities of our leading boilers makers, steam engineers, pipers, and others who have had more or less to do with the designing of such work, but it is nevertheless true.

"For drums up to 10 inches in diameter, made usually of ordinary steam pipe, the connections from the boilers are generally by means of the ordinary screwed tee. We will suppose, for instance, that four 60-inch boilers are set in a battery. Then the drum would be of 10-inch pipe, the steam pipe from each boiler, 5 inch, and they would connect with the drum with a 10'x10'x5' tee with inlet, outlet, and branch all threaded, and the whole screwed together.



ATTACHMENT OF NOZZLES TO STEAM DRUMS

"So far this is all right. But the pipes leading from the drum to the engine and other parts of the establishment are not usually the full size of the drum. They will oftener be found not over 6 inches in diameter, and are taken out by means of the usual forms of fittings. These pipes being led horizontally from the drum, with all centers at the same height, leaves a chance for water to collect in the lower part of the drum. This is apt to cause trouble unless the drum is dripped. This drip must be connected to all the boilers, and be furnished with valves so that the water may always be returned when but one boiler is running, and that one, any boiler of the battery.

"This arrangement works all right, but it is of the nature of a makeshift, and the work should be done in such a manner that it is not necessary.

"The connections to the boilers should be made by means of eccentric fittings. Figures 16, 17, 18, and 19, show in section, fittings adopted to this purpose, which would cost no more than those of the ordinary pattern, and the expense of the drip connection would be saved.

"Figure 16 shows an ordinary screwed tee, with the exception that the branch which receives the steam pipe from the boiler is dropped, so that the bottoms of the pipes forming the drum and that leading from the boiler are at the same level. Then when connection is made with any boiler in the battery, the drum always has a chance to drip freely back into the boiler. Under no circumstances can water collect in the drum, and no extra piping is required.

"Figure 17 shows a section through the branch of a cast-iron flanged tee, such as would be used in making the connection with a pipe larger than 10 inches in diameter. The same remarks apply as in the case of Fig. 16

"Figure 18 is a section through a nozzle such as would be put on a large drum, either of lap-welded pipe or a riveted-up drum. It should be put on eccentrically when connections to the boilers are made. For pipes leading out of the drum this is not essential, and the connection had better be made as shown in Fig. 21 further on.

"A word here about putting nozzles of this kind on to drums. A common way of doing it is shown in Fig. 20. A 'shim' or calking piece of wrought iron is put between the pipe and the base of the nozzle, and the rivets extend through pipe, shim, and flange of nozzle, and are driven from the outside. The joint is then made tight by calking the edge of the shim. As the rivets are driven from the outside against the rigid cast-iron flange, it is impossible to bring the flange and pipe into close contact, and very hard calking is resorted to. Even this generally fails to make a permanently good job, leakage is apt to set in soon, and is difficult to stop. Figure 18 shows a much better way to do this job. A patch is first riveted to the nozzles and calked at 'A.' This is then riveted to the pipe and calked at 'B.' By this means a permanently tight piece of work is secured.

"But a better way still to do this work would be to use a mild cast-steel nozzle, as shown in Fig. 19. The rivets can then be driven from the outside, the edge of the flange brought down closely to the pipe, and calked at 'A' in the usual manner. This form of nozzle would leave nothing to be desired. We believe that steel castings can easily be obtained at the present time possessing the requisite qualities for a nozzle of this kind.

"Figure 21 shows the best method of making the nozzle attachment to drums of large size, either riveted up or made of welded pipe, when the branch pipe is taken out on the center, although for some reason or other it is seldom used. The cast-iron screwed nozzle is simply riveted to the inside, which allows the rivets to be driven from the outside, the iron of the drum is brought closely down to the flange of the nozzle, and the calking edge is outside, in short, a *good job* is *easily* made, whereas, if the nozzle is put on the outside of the drum a *botch job* is made at much *greater cost*. Of course, if the drum is large enough to admit men inside to drive rivets, and do efficient calking, as good a job can be made in one case as in the other, but such large drums cannot be advised. They are useless and expensive appendages."

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

DISPOSAL OF HOUSE WASTE IN TIGHT CLAY SOIL.

"E. W. L.," Troy, N. Y., writes: "Please refer me to articles in THE ENGINEERING AND BUILDING RECORD, which I have from the beginning of its publication, covering the subject of sewage disposal like the instance I have in hand.

"The lot is 300 feet front by about 800 feet deep, and the greater part inclines upward from the front about one foot in ten, and at the ridge the house stands. There is no creek nor any sewer to which house drains can possibly be connected, the location being quite outside of the village limits. The soil is 8 feet and 4 feet deep on the rock, and is all very compact clay. In half a dozen places I caused test holes to be dug, and all filled with water in 24 hours, which later somewhat decreased in depth; but they always contain more or less water.

"It is desired to put in complete bath-room accommodations and water supply to the house. I think the only course is to build tight cesspools. But I prefer to ascertain if similar difficulties have received consideration in your paper."

[From the facts given it would seem that tight cesspools will have to be relied on and the expense of pumping them out incurred, though the depth of the lot, 800 feet, will probably allow for good sized ones, or several. The water may also be utilized, in some degree, in the garden. If first expense be no important consideration, a sufficient amount of clay might be removed, specially prepared soil substituted, and the subsurface irrigation system adopted. This, with suitable soil, is the best thing to do. It is described fully in "The Disposal of Sewage in Suburban Residences," by E. S. Philbrick, reprinted from this journal, and in William Paul Gerhard's little book (Van Nostrand's Science Series) on "The Disposal of Household Wastes."]

LIGHTING AND VENTILATING A SCHOOL BUILDING.

P. K. PATTISON, Superintendent of Public Schools, Colorado Springs, Col., writes:

"The Board of Directors of this city contemplate erecting a High School building, as per inclosed circular. We are much pleased with one plan, but would like expert testimony relating to the lighting, heating and ventilating of the building. Will you please answer the following questions?

"1. Do you think it best to light class-rooms 33x27 feet on one side *only*, or, on one side *mainly*, and have some additional light at the rear?

"2. Do you think a study-room, 65x45 feet, can be properly lighted by admitting light on the 65 foot side only, the room being on the north side of the building?

"3. Does the fact that direct sunlight never enters this room make it less healthful, or is this point of little importance in a school-room?

"4. Do you think this building will be best heated by the gravity system, or by the fan system?

"5. Is it right in principle to allow the gas and other products of combustion to enter from the furnace into the ventilating shaft and mingle with the foul air which is brought to its base from the entire building?

"Perhaps it is best for me to explain this last question more fully, and in so doing I will give you *data* for answering the fourth also.

"The system of ventilation seems very good, the opening for the admission of heated air into each room for 50 pupils being nearly four square feet. All the heated air is taken into the room at or near the top, and the foul air is taken out at or near the bottom. This foul air is conducted by large flues to the basement, and taken in a large duct beneath the floor of the basement to the bottom of the ventilating shaft, and is admitted thereto. This ventilating shaft is 6x8 feet. The smoke-pipe from the furnace enters this flue in the basement, and makes an upward turn, and is then cut off.

"There is some fear on the part of the Board that high winds, by adverse draughts, may carry the gases of combustion *downward* to the base of the shaft, and thence throughout the building. Do you think that there is any danger of such a result? When there is no fire in the furnace, a draught is to be created by a small stove in the base of the shaft.

"Is it right in principle to change the size of the smoke-pipe, say from a 20-inch pipe to a space 6x8? Is such an arrangement likely to give a good draught?

"In giving an opinion on the subject of lighting, you should keep in mind that the air here is very clear. An immediate reply will be of great service."

[It is not necessary for us to reprint the circular which accompanies this letter. The questions are answered in the order in which they are put.

1. It is best to light class-rooms on one side mainly so that the principal light shall come from the left of the pupils, and to have additional light at the rear.

2. A study room, 65x45 feet, and not more than 15 feet high, cannot be properly lighted for school purposes by windows in the long side only. The ratio of window to floor space, even in Colorado, should not be less than 18 per cent.

3. The fact that direct sunlight never enters a school room does make it less healthful. It is not important that the sunlight should always, or even usually, enter the room while it is occupied by the children, but the room should be exposed to the direct rays of the sun for at least two or three hours every day.

4. The meaning of this question is not quite clear, but it probably refers to ventilation rather than to heating. Presuming this to be the case the answer is that the most complete control and satisfactory working of the ventilation can be secured by the fan system, but that this requires more knowledge and attention on the part of the janitor than do aspirating shafts, that it is more likely to get out of order, and will cost somewhat more to run.

5. It is not right to turn the gaseous products of combustion into the main foul air shaft. The smoke pipe from the furnace should be continued up through the whole length of the ventilating shaft, and perforate its cap or cowl, having a separate cowl of its own.

The arrangement by which a 20-inch smoke pipe is discharged into a flue having 48 square feet of area will depend too much on the temperature and moisture of the external air and on the direction and force of the wind to give reliable and satisfactory results.]

MEMPHIS ORDINANCE REGARDING WATER-CLOSET ROOMS.

Latting & Bailey, of Memphis, Tenn., write: "We inclose herewith a copy of an amendment to our health ordinance, and would thank you to read same carefully and give us a free expression of your opinion of it. We ask this of you at the request of the most of our plumbers here as well as others, and a reply through the columns of your paper will be appreciated by us all."

[The ordinance in question reads as follows:

Be it enacted by the Legislative Council of the Taxing District of Shelby County, Tenn., that section 207 of the health ordinances be amended by adding thereto the following, as sub-section 207 a:

That all water-closets, privies and urinals hereafter constructed in any building used as a residence, within the Taxing District, shall be placed in a room not less than 5 feet in diameter, and said room shall have at least one window 2½x6 feet, with upper and lower movable glass sash hung on weights. There shall also be placed in the ceiling of said room a ventilator, at least 18 inches in diameter, connected with a pipe not less than 6 inches in diameter, leading through the roof of the house wherein said closet or urinal is placed. Said room shall not communicate directly by means of any door or opening whatever with any sleeping room, sitting room or apartment which is occupied by any human being during as many as two out of any 24 consecutive hours, nor shall any door, window or other opening of said room, be made within 3 feet of any apartment occupied by any human being during two out of 24 consecutive hours.

Any architect who prepares any plan of a house in violation of the above, shall be guilty of a misdemeanor, and subject to a fine of not less than $5 nor more than $50.

Any contractor or carpenter, constructing a closet in violation of the above, shall be guilty of a misdemeanor, and punishable by a fine of not less than $5, nor more than $50.

Any plumber putting in a privy, or urinal in violation of the above, or any owner or agent paying for same, or authorizing the construction of a closet or urinal in violation of the above, shall be guilty of a misdemeanor, and punishable by a fine of not less than $5 nor more than $50 for each offense.

Passed September 4, 1890.

W. D. Bethell, President.

Attest—Henry J. Lynn, Secretary.

This ordinance would seem to be too absolute and restrictive in its terms, since no possible exceptions are allowed even if approved by the sanitary officials. If the space is to be ventilated we know of no reason why an area of 4 feet square for a single water-closet or urinal is more dangerous to health than an area of 5 feet square, and we do not understand why a ventilator 18 inches in diameter is required for a 6-inch flue. Not having a copy of the health ordinances of the district before us we do not know how minute are the directions as to the kind of water-closets to be used, as to cisterns for flushing, traps, bath-tub connections, safe wastes, etc., all of which are more important from a sanitary point of view than anything specified in this ordinance. Undoubtedly a water-closet room should be ventilated, but to effect this air must be brought into the room as well as taken out of it. Probably the person who framed this ordinance intended that the window should be the fresh-air inlet, but to carry out the principle of detailed requirement it should have been specified that the window is to be so made that it cannot be kept shut. We do not know just what a Memphis privy may be, but if it resembles a New England or a New York privy it should not be allowed in a dwelling house at all. The motives for the framing and the passage of this ordinance are no doubt highly commendable, but we doubt the wisdom of such sweeping and non elastic legislation.]

THE METROPOLITAN MUSEUM ART SCHOOLS AT NEW YORK.

The prospectus for 1890–91 of the art schools of the Metropolitan Museum of Art, New York, has just been issued.

These art schools have been established by the trustees of the Metropolitan Museum of Art, in order to furnish superior opportunities for thorough instruction in design, drawing and painting, architecture and sculpture; especially to those who desire to acquire an artistic education applicable to industrial and commercial uses. Large, well ventilated rooms have been provided in the Museum, with superior art material and furniture. In order to offer all genuine students every facility in their work, a series of lectures are given, the privilege of visiting the Museum free of expense, prizes and certificates, so that all may measure their progress by the degree of their industry and application.

"Penny-in-the-slot" machines have been applied to the sale of gas for dwellings in England. According to the Bolton *Journal* the system has been introduced into that town, and while there are not many machines at present in operation there is thought to be no reason why the number should not increase. The system is supposed to appeal directly to consumers of limited means.

Novelties.

Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply indorsement.

SOME RECENT PLUMBING PATENTS.

The annexed illustrations of some plumbing devices, recently patented, are of interest:

Figure 1 is a urinal, whose flushing syphon K is operated by valve L, attached to float A by the bent lever C, pivoted at B. When the chain E is pulled it opens valve L and produces syphonage; when the chain is released the float A closes valve L. It also closes when the tank is filling before the water reaches the level of the valve seat. Peter White, St. Louis, Mo., is the patentee.

Figure 3 shows sections of a "retarding device for water-closet valves." C is the tank-valve chain, attached to a handle rod D, which works through a spherical shell E, containing an elastic hollow ball or diaphragm, F. This is attached to the rod and to the shell by collars G and H. The inside of the diaphragm is in constant communication with the external air through passage K. When the valve is operated, the diaphragm is forced into the position shown in B, and resists the movement of the handle L and chain C to a degree, adjustable by setting the valve screws at I and H. These control the air passages to the diaphragm. Timothy McHugh, Wakefield, Mass., is the patentee.

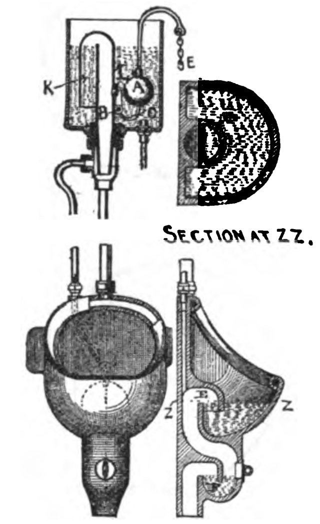


FIG. 1.

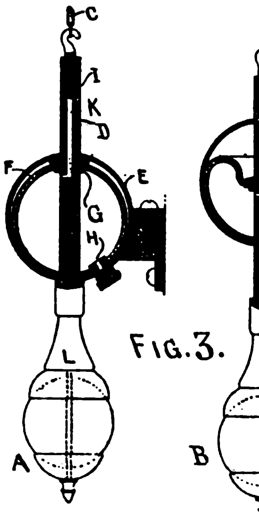

FIG. 3.

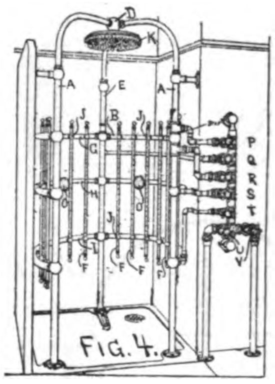

FIG. 4.

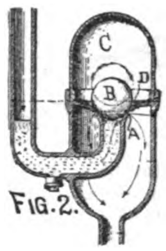

FIG. 2.

Figure 4 shows a "Needle Bath," with curved columns A E A supporting head D, and distributing pipes B H I to which the perforated spray pipes F F F, etc., are attached by hollow knobs J J, etc.; U and V are, respectively, hot and cold water supply cocks. The cock P controls the strainer K; Q controls spray in column E; R and I control distribution through pipes G and I, and S controls distribution through pipe H to sprays O O, etc. George Taylor, Jersey City, N. J., is the patentee.

Figure 2 is a section of a trap having a ball valve B, and an annular outlet A, and air inlet D in the discharge chamber C. William A. Mundy, Philadelphia, Pa., is the patentee.

PAVEMENT AND SEWER WORK IN DETROIT, MICH.

The report of the Department of Public Works of Detroit, Mich., for the year ending June 30, 1890, William Voight, City Engineer, and John Campbell, Secretary, give the following facts regarding new pavement, sewer work and public building:

During the past year about $11\frac{19}{100}$ miles of cedar block and cobblestone pavement, and $4{,}870\frac{88}{100}$ feet of asphalt pavement was laid. The cost of the cedar block and cobblestone pavement amounted to $267,597.90 or an average of about $1.35¼ per square yard. The cost of asphalt pavement amounted to $41.403.44 or an average of about $2.94 per square yard. In addition to the foregoing a portion of Cass Avenue was repaved with asphalt, and cost about $2.18 per square yard. In addition to this amount $3,135,80 was expended for extra paving, making the whole amount expended for repaving Cass Avenue $57,976.25.

With regard to complaints about cedar block pavements the report says:

> "Much has been said in denunciatory terms of cedar blocks as a material for pavement, but with what foundation for credibility the past usage of cedar block pavement will fully demonstrate. Wherever in the city of Detroit cedar block pavement has been laid on a proper grade, and permitted to remain undisturbed, its durability has been unquestionable, and perfectly satisfactory, but when it is constantly disturbed in making underground improvements its utility must, to a certain extent, be affected, and then follows the declamatory remarks as to the utility of cedar blocks for this purpose.
>
> "If the material will meet the requirements of the specifications for paving, and the work is done in accordance therewith, cedar block pavement is considered worthy to be classified with any material not excessive in its cost, therefore, instead of confining the censure to this material, let it be applied to the cause, to wit., the reckless manner in which the public is permitted to remove and replace the pavement after making underground improvements."

Seventy-six lateral sewers were constructed, about $10\frac{88}{100}$ miles long, at an aggregate cost of $44,650.57, an average of $81\frac{88}{100}$ cents per lineal foot. A new municipal court building was completed at $55,475.06, under supervision of the architects, Hess & Rossman. The plumbing pipes are all exposed, and particular attention was paid to the heating and ventilation.

THE NORTH RIVER BRIDGE.

The organization meeting of the North River Bridge Company, which was incorporated some time ago by special act of Congress, was held last week. All the incorporators were present either in person or by their authorized representatives. The minimum amount specified in the incorporating act, $1,000,000, is understood to have been subscribed, and the stockholders proceeded to the election of the following Board of Directors:

Jordan L. Mott, iron manufacturer, New York; John King McLanahan, of Hollidaysburg, Pa., engineer and iron manufacturer in Pennsylvania and in the South; James Adams, an engineer associated with Captain Eads in the St. Louis Bridge and New Orleans jetties undertakings; Thomas F. Ryan, banker, New York; Charles J. Canda, ex-Assistant Treasurer of the United States; Edward F. C. Young, President of the First National Bank of Jersey City, and William Brookfield, banker, of New York.

The Directors met immediately and organized by the election of the following officers: President, Jordan L. Mott; Secretary, M. H. Houseman; Treasurer, Charles J. Canda; General Counsel, Charles F. MacLean; Chief Engineer, Gustav Lindenthal.

The original plans of the bridge as designed by Chief Engineer Lindenthal, are for six railroad tracks on a single span over the river of 2,850 feet, but these plans are now being revised to provide for ten railroad tracks, for several street car tracks, and a promenade for foot passengers, and as soon as the plans are completed they will be submitted to the Secretary of War for his approval under the act of Congress.

THE MAINTENANCE AND OPERATION OF WATER-WORKS BY PRIVATE COMPANIES.

(Continued from page 253.)

12. *Public Hydrant Rental.*—Charge this account, and credit "public hydrant rental accounts receivable" with amount of charges for public hydrant rental as taken from journal.

Credit this account, and charge "cash" with all sums received from the public corporation for the right to use fire hydrants, in accordance with the terms of any contract between the company and the public corporation.

Treat rebates, errors, etc., the same as detailed in account No. 6.

13. *Private Hydrant Rental.*—Charge this account, and credit "private hydrant rental accounts receivable" with amount of charges for private fire protection as taken from Accounts Receivable Book.

Credit this account, and charge "cash" with all sums received from other than the public corporation for the right to use fire hydrants, except in those cases where the premises are supplied through a meter, and only the water used charged for, without any extra or specific sum being charged for the fire protection, which will only occur in special cases where the customer is a large user of water, and an exception is made in his favor.

Included in this account will be all sums received for the use of "stand-pipes," "sprinklers," etc., when used for the purposes of fire protection only and paid for accordingly.

Treat rebates, errors, etc., the same as detailed in account No. 6.

14. *Water Rates.*—Charge this account, and credit "water accounts receivable" with the gross amount of all bills for water rates.

Credit this account and charge "cash" with all sums received for water supplied, except under accounts 12 and 13.

Treat rebates, errors, etc., the same as detailed in account No. 6.

15. *Meter Rents.*—Charge this account, and credit "meter rents accounts receivable" with the gross amount of all bills for meter rents.

Credit this account, and charge "cash" with all sums received for the rent of meters.

Treat rebates, errors, etc., the same as detailed in account No. 6.

16. *Services and Repairs.*—Credit this account, and charge "cash" with all sums received for such items, all as detailed in account No. 10.

Charge this account, and credit "services and repairs accounts receivable and payable" with the gross amount of all bills for services, repairs, etc.

Treat rebates, errors, etc., the same as detailed in account No. 6.

17. *Miscellaneous Accounts.*—Credit this account, and charge "cash" with all sums received for such items as are detailed in account No. 11 as being charged to it.

Charge this account, and credit "miscellaneous accounts receivable," or the other proper accounts, with the gross amount or all bills made out for any purpose not already specified.

Treat rebates, errors, etc., the same as detailed in account No. 6.

18. *Bills Receivable.*—Charge this account, and credit the proper account with all notes received in payment of any account. When the notes are paid, credit this account, and charge "cash." When interest is received, whether included in the face of the note or paid in addition thereto, then credit interest account, and charge this account, or cash as the circumstances call for.

19. *Organization.*—Credit "cash," and charge this account with all sums expended for legal and clerical fees, notices, records, printing, traveling, and hotel expenses, cost of engraving and printing, so far as the same relates to the cost of the continuance of the organization of the company, including expenses of notices for annual meetings of the stockholders, but not special meetings of the stockholders for business purposes, which latter will be chargeable to that account for which the meeting was held.

20. *Construction.*—Charge this account, and credit "cash" with all sums paid for the original construction of the works, if done by contract, or, if the works were built by the company then credit each separate construction account with the amount charged, finally charging the same to "construction," and close the separate accounts. (See Water-Works Construction Accounts.)

After the original works are completed and in operation, charge all sums paid for new work to "construction," whenever it is in the nature of an addition, extension, or enlargement. But if it is merely to maintain, repair or replace in the original manner any particular part of the work, the cost will then be chargeable to other accounts.

21. *Real Estate.*—Charge this account, and credit "cash" with all sums spent in the care of real estate, including fences, bounds, drives, lawns, flowers, etc.; any new land, right of way, easement, etc., that may be bought will be charged to "construction."

22. *Water Supply.*—Charge this account, and credit "cash" with all sums paid to maintain the supply, such as cleaning and repair of wells, galleries, cribs, streams, springs, etc.

23. *Improvement of Water.*—Charge this account, and credit "cash" with all sums paid to improve the quality of the water, either by filtration, settling, aeration, flushing, or otherwise.

24. *Storage.*—Charge this account, and credit "cash" with all sums spent for the maintenance and repair of any dam, reservoir, well, basin, etc., intended and used merely as a place to store water.

25. *Water Power.*—Charge this account, and credit "cash" with all sums spent for the maintenance and repair of all water power, including dams, overflows, head-gates, sluices, waste-gates, wheel-pits, tail-races, but not buildings or water-wheels.

26. *Conduits, Force or Gravity Mains.*—Charge this account, and credit "cash" with all sums spent for the maintenance and repair of all conduits, force or gravity mains, when used exclusively as such.

27. *Distribution.*—Charge this account, and credit "cash" with all sums spent for the maintenance and repair of such pipes, gates, hydrants, blow-offs, etc., as belong exclusively to the distribution system; "force or gravity mains" ending and "distribution" commencing at the first hydrant or other branch.

28. *Buildings.*—Charge this account, and credit "cash" with all sums spent for the maintenance and repair of all buildings, including painting.

29. *Foundations.*—Charge this account, and credit "cash" with all sums spent for the maintenance and repair of all foundations for machinery and boilers, including pump-wells, excepting water wheels, etc.

30. *Water Wheels.*—Charge this account, and credit "cash" with all sums spent for the maintenance and repair of all water wheels, jack and crown shafts and gears, but not power-pumps.

31. *Boilers.*—Charge this account, and credit "cash" with all sums spent for the maintenance and repair of all boilers, including their setting, grate-bars, and all fittings and connections above the foundation and in the boiler-room.

32. *Pumps, either Steam or Water Power.*—Charge this account, and credit "cash" with all sums spent for the maintenance and repair of all pumps, whether operated by water or steam. If operated by steam, then the maintenance and repair of the engine or steam end of the pump will be charged to this account, including all fittings and connections above the foundations, in the engine rooms: include in this account packing, but not oil or waste.

33. *Fuel.*—Charge this account, and credit "cash" with all sums spent for fuel of all kinds and all expenses connected therewith, either in transporting, preparing, or handling the same until it is in its final receptacle, ready for use by the fireman.

34. *Oil and Waste.*—Charge this account, and credit "cash" with all sums spent for lubricating, or cleaning oil and waste used about the works, but not including illuminating oil.

35. *Lighting.*—Charge this account, and credit "cash" with all sums spent for lamps, gas, or electric light fixtures, illuminating oil, gas, or electricity.

36. *Stand-pipe.*—Charge this account and credit "cash" with all sums spent for maintenance or repair of stand-pipe, including connections, foundations and painting.

37. *Distributing Reservoir.*—Charge this account, and credit "cash" with all sums spent for maintenance and repair of reservoirs built and used for the purposes of distribution.

38. *Meters.*—Charge this account, and credit "cash" with all sums paid for meters, including freight, setting, caring for, and reading the same.

Credit this account, and charge "cash" with all sums received from the sale of meters.

At the end of the year, when "meter rents accounts receivable" is closed, it will be closed into this account, and this closed into "balance."

39. *Salaries.*—Charge this account, and credit "cash" with all sums paid the officers (not employees) of the company for services, but not expenses, which latter are chargeable to the account of the department for which they were incurred.

40. *Legal Expenses.*—Charge this account, and credit "cash" with all sums paid for counsel or court fees, together with legal printing, notices, etc., unless the same is connected with organization, when they will be charged to that account.

41. *Superintendent.*—Charge this account; and credit "cash" with all sums paid the superintendent for services. Special expenses of the superintendent will be charged to the account of the department for which they were incurred.

42. *Engineering.*—Charge this account, and credit "cash" with all sums paid for advice, plans, supervision, etc., of a technically engineering nature, either in connection with the maintenance or repair of the works.

43. *Engine-men and Firemen.*—Charge this account, and credit "cash" with all sums paid to engine-men employed in operating machinery, also firemen and watchmen employed about the pumping machinery buildings.

44. *Office Expense.*—Charge this account, and credit "cash" with all sums paid on account of office or office assistants, including rent, fuel, stationery, printing, postage, telegrams, book-keeping and clerical work, either in or out of the office.

45. *Livery.*—Charge this account, and credit "cash" with all sums paid for horses, wagons, harnesses, etc., and the care and maintenance of the same, also for sums paid out for the hire of extra or special teams, to take the place of any of the regular teams, either to relieve the latter or in case of temporary repairs or accidents.

All teams bought and used, or hired for use, exclusively for any purpose which has a separate account should be charged directly to that account, including drayage.

This account is intended to cover the cost of the superintendent's team or any other team used for the general purposes of the company.

46. *Interest.*—Charge this account, and credit "cash" with all sums paid on account of interest on bonds, bills payable, etc.

Credit this account, and charge "cash" with all sums received for accrued interest on bonds, bills receivable, etc.

47. *Discount and Commission.*—Charge this account, and credit "stock," "bonds," "bills payable," or "cash," as the case may be, with the difference between the face value of any stock, bonds, or bills payable, and the amount received for the same, or for expenses incurred in the sale of the same, including collection charges on the same, as well as on drafts or other bills of exchange, *except* when such discounts or collection charges are merely direct interest charges for use of the money during time of collection or until the note or bond is due, when it is charged to "interest."

48. *Taxes.*—Charge this account, and credit "cash" with all sums paid for taxes, whether town, city, county or State.

49. *Insurance.*—Charge this account, and credit "cash" with all sums paid for insurance on buildings, stock, etc., except in case of insurance on stock or material in transit, when it would be charged to the cost of that stock or material.

50. *General Expense.*—Charge this account, and credit "cash" with all sums paid out for anything not properly chargeable to any of the foregoing accounts, or which is not of itself of importance enough to have an account of its own.

(To be continued.)

The British *Journal of Gas Lighting, Water Supply,* etc., in referring to the collapse and sudden emptying of a reservoir at Castleford, England, says that investigation led to the discovery of a large cavity in the bottom of the reservoir through which the water had disappeared. As no flooding of the adjacent parts took place, it is surmised that there must be cavities of enormous dimensions beneath the reservoir, or that the water may have found its way into some of the disused colliery workings of the neighborhood.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE.

For works for which proposals are requested see also the "Proposal Columns, pages i-ii-271.

WATER.

For Additional Water Items see Proposal Columns.

Sheffield, Ala.—The City Council has taken the first steps towards a water-works system by engaging Johnson & Flood, hydraulic engineers, to make the preliminary survey.

Adairsville, Ga.—A new system of water-works is soon to be established at this place.

Lincoln, Ill.—Reports say that a new company has offered to establish a system of water-works at this place.

Jellico, Tenn.—A new system of water-works is proposed for this place. For complete particulars address the Mayor, as above.

Hebron, Iowa.—The sum of $25,000 has has been appropriated at this place for the purpose of establishing a system of water-works.

Helena, Mont.—The Eureka Reservoir Canal and Irrigation Company has been formed at this place. Capital stock, $200,000. Z. T. Burton is President.

Dover, N. J.—Extensions are to be made to the local water mains.

Wilton, Iowa.—The taxpayers of this place have voted to make an expenditure of $14,000 on a system of water-works.

Rockville Center, L. I.—Efforts are being made to have a system of water-works at this place.

Kirkwood, Mo.—The Sunset Hill Electric Light, Water and Power Company has made a proposition to erect an electric light plant and water-works at Meramec Park to supply Kirkwood and neighboring villages with water from the Meramec River.

Mellette, S. D.—The County Commissioners of Spink County have decided to submit to a vote of the people at the general election, November 4, the question of issuing county bonds for a county artesian well system.

Hopkinsville, Ky.—The long discussed water-works question at this place has terminated in the formation of a committee to go ahead with the matter, as it is probable that important steps will be taken at once.

Arkadelphia, Ark.—The City Council has appointed a committee to take the first steps towards establishing a system of water-works.

Trinidad, Col.—This place voted, August 26, in favor of establishing a system of water-works.

Newmanstown, Pa.—Reports say that this place is to have water-works.

Milford, Mass.—An additional stand pipe is to be established at this place.

Halstead, Kan.—It is proposed to revive the water-works question at this place, which was started some time ago but which gradually died out.

Sumter, S. C.—A water supply project is being considered by the City Council. Particulars can be had by addressing W. M. Graham, as above.

Wichita Falls, Tex.—This place is to have a system of water-works.

Columbia, S. C.—The Water-Works Committee recommends the purchase of water wheels and pumps at the cost of $25,000 to increase the supply of water.

Exira, Iowa.—An appropriation has been made at this place for the purpose of establishing a system of water-works.

Sioux City, Iowa.—The Leeds Water-Works Company has been organized at this place.

Marshalltown, Iowa.—A system of water-works is to be established at this place.

Middlebury, Vt.—The people of this place have decided to establish a system of water-works. Charles J. Starr can furnish particulars.

San Diego, Cal.—J. D. Schuyler, of this place, writes: "This city has taken the preliminary steps toward constructing an independent pipe distributing water-works system, with the expectation of buying water from the San Diego Flume Co., whose proposition to furnish as much as is required has been accepted. Mr. James D. Schuyler was employed to lay out a plan for the new system, covering 61.3 miles of pipe and including two distributing reservoirs in the city park. His plan was adopted by the council, and an election was called for October 4, to vote on the issuance of $326,000 in bonds, which is the limit of the city's capacity to bond. The citizens are almost unanimous in the determination to have works of their own, and cheaper and better water, and the bonds will undoubtedly carry."

Gaffney City, S. D.—Reports say that the prospects for establishing a system of water-works at this place are excellent. The question is to be decided by a vote of the citizens to be held at an early day.

Goshen, Ind.—The Town Clerk at this place writes: "The City Council approved and ratified the following contracts for improving our water-works system, at a regular session held September 15: For the Hughes' pumping engine, $3,990; addition to pump house, $1,200; extension to water mains, iron 10-inch pipe, $4,633; water supply additional to what we now have, $4,075. L. W. Wanner is superintendent of water-works."

Westfield, Pa.—The Town Clerk at this place writes: "The only steps taken for water-works so far is the incorporation of the Westfield Water Co., with a capital of $25,000, of which J. H. Millar is president and T. M. Leonard is secretary, both of Westfield, Pa."

Knoxville, Tenn.—Water-Works Superintendent R. N. Hood, writes: "It is contemplated to put in new pumps, build two new reservoirs, additional to the ones we now have, and to add about 12 miles of new mains. The reservoirs we will build will hold 3,200,000 gallons."

Henrietta, Tex.—J. B. Hopkins, and others, have organized the Henrietta Improvement and Water Company at this place, with a capital stock of $50,000.

San Angelo, Tex.—The water supply at this place is to be increased and otherwise improved.

Monticello, Ill.—City Clerk Robert Huston writes: "At our next meeting specifications will be submitted for a tubular artesian well of 6-inch pipe, and operations to commence as soon as possible."

Bay City, Mich.—The people of this place have decided to settle the question of expending the sum of $50,000 on water-works improvements, at a public election to be held in November.

Tacoma, Wash.—Surveys are being prepared for the new water-works system proposed for this place.

Sorrento, Me.—Town Clerk Henry Boynton writes: "No steps have been taken to build the water-works at Sorrento, except voting to do so at meeting of Land Company."

Monmouth, Ill.—City Clerk J. Arthur Stevenson writes: "We are spending $25,000 in extending the water mains in this city. The contractor is W. W. McCullough, of Monmouth, Ill."

St. Paul, Minn.—The Water Board on September 22 opened the bids for the furnishing of the new pumping machinery at the McCarron Lake station. The proposals were three in number, and as follows: H. R. Worthington, of New York (bids covering two different makes of machinery): First bid, $24,700; second bid, $27,000. Holly Manufacturing Company, of Lockport, N. Y. (bids covering two different makes of machinery): First bid, $28,000; second bid, $22,500. To both of these amounts $2,000 must be added for setting the boilers and arranging the steam pipes. E. P. Allis & Co., Milwaukee, $32,000. The bids were referred to Engineer Somers for his report as to which is the lowest bid.

San Antonio, Tex.—An exchange prints the following: "On September 30, the taxpayers of this place are to vote on the proposition to buy the water-works plant from Colonel G. W. Brackenridge for $2,000,000. A call has been issued for a mass meeting of citizens at the court house on Saturday night, when it is hoped to inject life into the campaign. It is pretty generally believed that the proposition will be beaten."

Rochester, N. Y.—At a meeting of the Common Council's additional water supply Committee, held September 19, a request was made to the Chief Engineer to prepare approximate estimates of the cost of obtaining 15,000,000 gallons of water per day for an additional supply from Hemlock Lake on one hand and Lake Ontario on the other; also the approximate cost of the preliminary surveys for the two projects. He is to report at the next meeting of the Committee.

Centralia, Wash.—The surveys for the water-works system which is to supply this place from the Newaukum River have been finished. A. J. Miller, President of the Bank of Centralia, has the contract.

Darlington, S. C.—City Clerk S. S. Burch, writes: "We are erecting water-works here now—it is a corporation, and I respectfully refer you to Mr. C. S. McCullough, President, for any further information."

Aberdeen, Wash.—The City Council has had plans prepared for a new system of works to cost about $50,000, The question of issuing bonds for that amount is to be voted upon. The scheme embraces a 2,000,000-gallon pumping plant, which will pump water into a tank 230 feet above the city. A reservoir will also be constructed.

La Grange, Ill.—This place is to have a system of water-works.

Babylon, L. I.—The taxpayers of this place will settle the water-works question at a public election to be held September 29.

Elmhurst, Ill.—Village Clerk A. Barder writes: "The water-works company has not organized yet, but they will do so in the near future. Engineers are just at work to get a correct survey and particulars. For any further particulars as to organization, contracts, etc., I refer you to Mr. W. H. Emery."

Macon, Ga.—Regarding the report that the water-works at this place were to be improved, City Clerk B. Smith writes: "The water-works are owned by the Macon Gas and Water Company, and I do not know of any steps being taken to improve them."

Hempstead, Tex.—For important information regarding the projected water-works system for this place, address C. C. Amaler, as above.

Water-Works.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Allegheny, Pa.; Atlanta, Ga.; Sutton, Neb.; Fulton, Ky.; Homestead, Pa.; Marseilles, Ill.; West Troy, N. Y.; Dallas City, Ore.; New York City; Ellsworth, Kan.; Austin, Tex.; Toronto, Can.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

Manchester, Va.—Regarding the report that this place was to have a sewerage system, Auditor J. B. Vaden, writes: "No steps taken in that direction."

San Francisco, Cal.—City Surveyor Smith has filed plans for a sewerage system for Point Lobos District with the Board of Supervisors. The district proposed to be sewered covers about 1,700 acres.

Kansas City, Mo.—Contractor Patrick McDonald has forfeited the contract for the construction of the $50,000 sewer at this place, and the work is to be re-advertised. City Engineer Butts can furnish information.

Sewers.—See our Proposal Columns for information regarding the sewer construction at the following places: Iron Mountain, Mich.; Davenport, Iowa; New York City; Key West, Fla.; Detroit, Mich.; Toronto, Can.; Denver, Col.; Dubuque, Ia.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns

Quanah, Tex.—It is reported that $10,000 has been raised by citizens of this place for building the bridge across the Red River, which will unite Hardeman and Green counties.

New Haven, Conn.—The County Commissioners of New Haven and Fairfield Counties will, it is said, shortly ask bids for a bridge over the Housatonic River between the towns of Derby and Huntington. They expect to spend about $70,000.

Scranton, Pa.—It is reported the city will issue bonds for the erection of several iron bridges.

St. Paul, Minn.—Bridges are to be built at Como, Lexington and Snelling Avenues, the Great Northern road to bear one-third of the expense.

Reading, Pa.—The County Commissioners have received bids for the construction of a new bridge to span the Little Swatara Creek near Freytown, Bethel township. The bids presented for the iron works were these: Canton, O., Bridge Company, $22.65 per lineal foot; Pittsburg Bridge Company, $22.98; Berlin Bridge Company, $23; Smith Bridge Company, $22.95; Variety Iron Works, $43 40; Dean & Westbrook, $23.87; John Dennithorn, $23.75; Penn Bridge Company, $22.40. The contract for this work was awarded to the Penn Bridge Company, of Beaver Falls. The contract for the mason work was awarded to Joseph P. O'Reilly, this city. The bids for the masonry were: Joseph Rohrbach, $1,617, and additional foundations $7.40 per yard; Joseph P. O'Reilly, $882 and $79; Jared G. Yarnell, $1,224.50 and $4.75; Elias Dieffenbach, $1,150 and 37 cents per yard; A. A. Spannuth, $1,700 and $5.

Rockville, Conn.—The town of Ellington proposes to replace the bridge across Broad Brook River at Ladd's mills with an iron structure.

Norfolk, Va.—It is proposed to build a bridge from this city to Ghent at an estimated cost of $35,000. For particulars address A. P. Thom, as above.

St. Paul, Minn.—The plans for the superstructure and river piers for the Broadway bridge over the Mississippi River, at this place, have been sent to Washington by City Engineer Rundlett for their approval by the federal authorities. When the City Engineer receives official notification of the approval of the plans, bids for the superstructure will be advertised for. The estimated cost of the structure is $350,000.

Pittsburg, Pa.—Reports say that numerous citizens of the West End propose to bridge the Ohio River from that locality to Allegheny.

Washington, D. C.—The House Committee on Commerce has reported favorably the bill to authorize the New Orleans Terminal Railway and Bridge Company to build a bridge over the Mississippi above New Orleans.

Columbus, O.—The Board of Public Works has ordered the City Engineer to prepare plans and specifications for the High Street viaduct. The plan may involve iron or steel or stone columns.

Lincoln, Neb.—The local authorities have decided to construct two viaducts in this city. For particulars address Mayor Graham, as above.

Scranton, Pa.—The Executive Committee appointed by the recent citizens' meeting for the purpose of presenting to the people the advantages to be attained by bonding the city for the new bridges is making every effort to bring the project to a successful termination. It is probable that the City Engineer will soon be instructed to prepare plans, specifications, etc., and then it is likely an opportunity will be offered to bid on the work.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: Middlesborough, Ky.; San Antonio, Tex.; Knoxville, Tenn.; Dublin, Ga.

NEW DEPOTS.

Norwich, Conn. — The New London Northern Railroad proposes to erect a depot at this place.

STREET-WORK AND PAVING.

Mt. Vernon, N. Y.—This village has appropriated $10,000 to macadamize the streets. Bids are now being received for part of the work.

Canton, O.—The City Council has instructed City Engineer R. R. Marble to draw up plans for three miles of streets to be paved next spring.

Buffalo, N. Y.—Considerable paving is to be done in this city. The City Engineer can furnish particulars.

Streator, Ill.—This city has decided to pave its principal streets with brick next spring.

GAS AND ELECTRIC LIGHTING.

Wetumpka, Ala.—This city has, it is reported, contracted with a Chicago (Ill.) company, for the erection of an electric light plant.

Orono, Me.—There is talk of lighting the streets and dwellings of this place by electricity. The Committee on Street Lights is ready to negotiate with some parties regarding the question.

Colusa, Cal.—There is a project at this place to establish an electric lighting plant. Address James Anthony, of Chico, Cal., for details.

Delhi, N. Y.—The long projected electric light plant for this place is about to be established.

Leechburg, Pa.—This place is to establish electric lights.

Monroe, Mich. — This place will soon have electric lights.

La Grange, Ill.—Electric lights will soon illuminate the streets of this place.

Hinton, W. Va.—A plant to cost $20,000 is to be established at this place by L. M. Dunn and others.

Pinckneyville, Ill.—A stock company has been formed for the purpose of putting in an electric light plant at this place, provided the citizens will guarantee them sufficient patronage to make the scheme pay.

Cameron, Mo. — A franchise has been granted to J. M. Anderson to establish and operate an electric light plant at this place.

Chicago, Ill.—The Whiteside and Fuller Electric Manufacturing Company has been incorporated here with a capital stock of $100,000. The incorporators are: W. H. Whiteside, W. H. Pettibone, W. D. Carlile and others. The company will manufacture electric machinery and appliances.

Stanberry, Mo.—F. A. Weimer and others have incorporated an electric light company, and a plant will be established at once. Proposed expenditure, $7,000.

Brussels, Ont.—An electric light plant will soon be in operation at this place.

Georgetown, Cal.—Reports say that a company is to light this place with electricity, and that a line will also be run to Silver Plume for illuminating purposes.

Keokuk, Iowa.—There is talk of substituting electricity for gas for public lighting at this place.

Wilton, Iowa.—This place is to have electric lights.

Kingsville, Ont.—The Town Council has agreed to loan to the Citizens' Gas Company the sum of $15,000 for the purpose of enabling the latter to lay its mains through the town.

Richmond, Va.—An ordinance has been passed authorizing the Committee on Electric Light to advertise for bids for furnishing the city with electric light for 12 months or a shorter period, from February 8, 1891.

Clyde, N. Y.—This place will soon have an electric light plant.

Mascoutah, Ill.—An electric light company has been formed at this place.

Marion, Pa.—M. C. Watson can give particulars regarding the gas company which will establish a plant, with a capital stock of $50,000.

Buffalo, N. Y.—Reports say that the authorities of this city are considering the matter of installing and operating on public account an arc lighting plant.

Hopkinsville, Ky.—This place is soon to have electric lights.

Greenville, Tex.—The local officials are considering the question of having an electric light plant.

Jamaica Plain, Mass.—The proprietors of the Jamaica Plain Gas Light Company have voted to extend their mains in the direction of the adjoining district of West Roxbury.

Delphos, O.—It is probable that extensive improvements will shortly be made to the plant of the Delphos Electric Light and Power Company.

Jamaica, L. I.—The following proposals for lighting the public streets, etc., of this place have been opened as follows: Robert S. Nash, of New York City, offered to light the village, furnishing as many electric lights as the Trustees desired, for $19 a lamp per year. The Jamaica Gas Light Company, with gas, at $25 a lamp per year, with an addition of $4 a year for each year for cleaning, lighting and extinguishing; electric light, $18 per lamp. The Woodhaven Gas Light Company, gas, $25 a lamp per year. The National Electric Manufacturing and Construction Company, $17.50 per lamp, 32 candle-power, incandescent light. George B Ellery, Heisler electric light, 32 candle-power, $18 per lamp. The contract was awarded to the National Manufacturing Construction Company.

Electric Railways.—New electric railroads will be built, and improvements will be made to those already established at the following places: Owosso, Mich.; Allentown, Pa.; Amsterdam, N. Y.; Sacramento, Cal.; Tacoma, Wash.; San Francisco, Cal.; Natick, Mass.

BIDS OPENED.

Peru, Ill.—D. C. Harr, postmaster of La Salle, Ill., plumber and steam heating engineer, has been awarded the contract, at $11,240, for heating by steam the new monastery here. There were 18 bidders.

Marion, Ind.—Goehring & Pierson, of Indianapolis, have been awarded the contract at $106,625, for the construction of a hospital and other buildings at the Soldiers' Home.

St. Paul, Minn.—The South St. Paul City Council has let the contract for the steam heating plant in the new city hall to Stewart & Larson, of St. Paul, for $1,511.

The contract for building an addition to the Stickney School was awarded to J. M. O'Grady, of St. Paul, for the sum of $3,000.

Tacoma, Wash.—The following proposals for the erection of the Court House at this place have been opened by the commissioners: John F. Long, $270,000; Lillis & Goss, $279,900; R. Smiley, $307,557; Bassford & Holtz, $308,940; J. D. Milligan, $330,000; Fred Gribble, $341,806; Frank Cantara, $353,064; Sharp & Singleton, $373,300; Nicholas & Crothers, $386,230. Contract awarded to John F. Long.

San Francisco, Cal.—Bids for construction of Section B of the sea-wall, including the filling of the wall, the thoroughfare and the wharf, have been received by the Harbor Commissioners as follows: F. J. & J. V. Owens, $93,320; Antonelli & Doe, $109,890; S. F. Bridge Company, $98,120; Warren & Malley, $103,480; W. C. Wing, $130,600; J. W. McDonald, $131,700; John Kelso, $117,160; B. McMahon & Son, $138,800. The bid of the California Bridge Company was not considered on account of failure to furnish samples of rock to be used. Contract was let to F. J. & J. V. Owens. Their bid was $14,000 less than Engineer Manson's estimate. The section begins at the foot of Powell Street, and extends along the city front to the westerly side of Taylor Street. It is 1,000 feet in length. The specifications call for 70,000 tons of rock, 84,000 cubic yards of earth, and material for the construction of a wharf all along the line.

GOVERNMENT WORK.

Washington, D. C.—The following proposals for the work named were opened on the given dates by the Supervising Architect of the Treasury Department:

Charleston, W.Va.—Low temperature, hot-water heating and ventilating apparatus for the extension of the United States Post Office, Court House, etc., at this place, opened September 24. Bidders: Crook, Horner & Co., Baltimore, Md, $6,043; L. M. Evans Construction Co., New York, $7,841; John Lyons, Washington, D. C., $5,175.75; C. Bayamin, Buena Vista, Va., $4,975.

Watertown, N. Y.—Erection and construction (except heating) of the United States Post Office at this place, opened September 19. Bidders: Peter Pitkin & Son, Rochester, N. Y., Gouverneur marble, $84,000; Warsaw blue stone, $81,000. E. J. Bell, Portland, Conn., Middlesex brown stone, $56,000. McAllister & Dall, Cleveland, O., New York marble, $62,997; Ohio blue stone, $60,728; R. Mara & Co., Syracuse, N. Y., Onondaga, $69,400; Amherst, $70,500; Berea, $68,300; Patrick Philips, Watertown, N. Y., Bannister blue limestone, $52,065.73. William H. Stemburg, Wichita, Syracuse limestone, $54,987. Hughes Bros., Syracuse, N. Y., Berea, $53,870; Amherst, $55,870; Indiana limestone, $56,370; Georgia marble, $59,370; Chaumont limestone, $54,000; Onondaga limestone, $56,850. John Moore, Syracuse, N. Y., Gouverneur marble, $55,000; O'Brien & Hoolihan, Syracuse, N. Y., New York marble, $56,864. George Van Horn, Washington, D. C., St. Lawrence, Gouverneur, New York, $77,284; Berea, $68,284.26.

INDUSTRIAL.

Peoria, Ill.—It is proposed to build a tunnel a quarter of a mile long for the benefit of railway travel. The Peoria Improvement Association can give information.

Weldon, N. C.—A charter has been granted to the Great Falls Water Power Manufacturing and Improvement Company, which has for its principal object the development and utilization of the water power of the Roanoke River between this place and Gaston.

Boston, Mass.—The New England Telegraph and Telephone Company is considering the feasibility of replacing all old cedar poles with iron and steel.

Long Branch, N. J.—The Commissioners at a special meeting September 16, decided to restore the Boulevard and build a bulkhead and jetties the entire length of the town limits. A double track electric railway will be laid. The roadway will have a promenade on one side, a drive on the other, and the tracks in the middle.

New York City.—The Armory Board has decided to build an armory in West Fourteenth Street, on the site of the old Twenty-second Regiment Armory, and upon two additional lots west of it. President Coleman has been authorized to negotiate for the purchase of the site for $390,000. When built the new armory will be used by the Ninth Regiment.

WANTED.

TOO LATE FOR CLASSIFICATION.

AN ARCHITECT OF EXPERIENCE DESIRES to form partnership with an architect having a good practice and doing first-class work, in some eastern or southern city, coast city preferred. Address ARCHITECT, Box 113, office of THE ENGINEERING AND BUILDING RECORD, New York.

A YOUNG MAN WITH FOUR OR FIVE YEARS' experience in civil engineering and surveying, desires a position as leveler or rodman on preliminary surveys or sewer construction; salary moderate; can give good references. Address P. L. R., Box 73, this office.

POSITION WANTED BY A YOUNG MAN with ten years' experience in architect's and builder's office, familar with practical details, construction and drawings; fair draughtsman. Address Q., Box 72, this office.

PROPOSALS.

(Continued from page ii.)

U. S. ENGINEER OFFICE, ROOM 62, ARMY Building, New York, September 24, 1890.—Sealed proposals, in triplicate, will be received at this office until 12 o'clock noon on October 25, 1890, for furnishing materials and **CONSTRUCTING A PILE WHARF** at SANDY HOOK, N. J. The attention of bidders is invited to Acts of Congress, approved February 26, 1885, and February 23, 1887, Vol. 23, page 332, and Vol. 24, page 414, Statutes-at-Large. For specifications, blank forms, and all information, apply to the undersigned. G. L. GILLESPIE, Lieut.-Col. of Engineers. 20

SEPTEMBER 25, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M. on the 15th day of October, 1890, for all the labor and material and fixing in place complete the low-pressure **STEAM HEATING AND VENTILATING APPARATUS** for the U. S. Court-House and Post-Office Building at CHARLOTTE, N. C., in accordance with drawings and specification, copies of which may be had on application at this office or the office of the Superintendent at Charlotte, N. C. Each bid must be accompanied by a certified check for $100. The Department will reject all bids received after the time herein stated for the opening of the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be inclosed in an envelope sealed and marked "Proposal for the Low-Pressure Steam Heating and Ventilating Apparatus, for the U. S. Court-House and Post-Office Building at Charlotte, N. C.," and addressed to JAS. H. WINDRIM, Supervising Architect. 18

PROPOSALS.

Notice to Contractors.

SEALED BIDS FOR THE GRADING, SEWERING, DRAINING, MACADAMIZING, and otherwise improving the streets and avenues of PELHAM HEIGHTS, WESTCHESTER CO., N. Y., in accordance with the contract and specifications to be furnished by the Engineer in charge, No. 152 Prospect Avenue, Mt. Vernon, N. Y., until 12 o'clock M. of WEDNESDAY, October 15, 1890.

No bids will be received unless accompanied by a certified check for five hundred dollars as a guarantee of signing contract if bid is accepted.

All bids must be made upon the blank forms furnished by the engineer.

The owners reserve the right to reject any or all bids or parts of bids. Bids must be made for the whole work.

The sewers are to be pipe sewers. The property is situated at Pelhamville Station, N. Y., N. H. & H. R. R.

The following is a general summary of the estimates:

Grading	81,399	cubic yards.
Macadamizing	78,615	square yards.
Gutters	49,930	lineal feet.
Sidewalks	27,693	square yards.
Sodding	35,903	" "
Trees to be planted	1,645	
Sewerage	30,318	lin. ft. of pipe with accessories.
Drainage	13,000	" " "
Water pipe	30,986	" " "
Gas pipe	30,000	" " "

Plans can be seen, and specifications and other printed forms obtained upon application to the Engineer in charge.

BEN. L. FAIRCHILD,
GEORGE B. CRUMBIE, } Owners.
JOHN F. FAIRCHILD,
Engineer in Charge. 18

WATER-WORKS, Homestead, Pa.—Proposals are wanted until October 1, for furnishing plans, specifications, etc., and superintending the construction of a system of water-works at this place. Address James M Hoover, Chairman Water-Works Committee, as above.

BRIDGE, Knoxville, Tenn —Proposals are wanted until October 4, for the erection of an iron bridge on Fifth Avenue, this city. Address the City Engineer, as above.

AQUEDUCT, New York City. — Proposals are wanted until October 8, for building 11 head-house superstructures, etc., for the shafts of the new Croton Aqueduct. Address John C. Sheehan, Secretary of the Aqueduct Commission, as above.

PUMPING ENGINES, Toronto, Can.—Proposals are wanted until October 20, for furnishing two duplex pumping engines, with a 10,000,000-gallon capacity, also the necessary boilers, etc., for the same. Address William J. Hill, Chairman Committee on Water-Works, as above.

PAVING, New York City.—Proposals are wanted until September 30, for paving certain streets. Address the Department of Public Works, as above.

PIPE, ETC., Marseilles, Ill.—Proposals are wanted until October 4, for furnishing a quantity of water-pipes, specials, etc. Address C. L Stinson, City Clerk, as above.

DREDGING, New York City. — Proposals are wanted until October 13, for dredging for proposed bulkhead wall at East One Hundred and Second Street section on the Harlem River. Address the Department of Docks, Pier A, North River, as above.

STATE CANALS, Albany, N. Y.—Proposals are wanted until October 6, for doing certain work on the State canals. Address Edward Hannan, Superintendent of Public Works, as above.

WATER SERVICE SYSTEM, West Troy, N. Y. —Proposals are wanted until October 6, for furnishing material and labor complete for a water service system at the Watervliet Arsenal. Address Lieut -Col. C. H. Parker, U. S. A., as above.

CARPENTER AND IRON WORK, Toronto, Can.—Proposals are wanted until October 1, for the rough carpenter work and the constructional iron work of an office building in this city. Address Knox & Elliott, architects, corner Queen and Victoria Streets, as above.

BRIDGE, Dublin, Ga.—Proposals are wanted until October 20, for the erection of an iron bridge across the Oconee River, at this place. Address John F. Duncan, Ordinary, as above.

SEWERS, Detroit, Mich.—Proposals are wanted until October 6, for the construction of numerous sewers in this city. Address the Board of Public Works, as above.

MACADAMIZING, Dunkirk, N. Y.—Proposals are wanted until October 3, for macadamizing certain roads in the vicinity of this place. Address Edward Madigan, City Clerk, as above.

SEWERS, Denver, Col.—Proposals are wanted until October 17, for the construction of certain sewers in this city Address F. B. Crocker, President of the Board of Public Works, as above.

SEWERS, Toronto, Can.—Proposals are wanted until October 7, for the construction of sertain sewers at this place. Address John Shaw, Chairman Committee on Works, as above,

PAVING, New York City.—Proposals are wanted until October 7, for doing certain streets paving. Address the Department of Public Works, as above.

DREDGING, New York City.—Proposals are wanted until October 9, for dredging for a pier at the foot of East Twenty-second Street. Address the Department of Docks, Pier A, North River, as above.

ROADS, Tompkinsville, S. I.—Proposals are wanted until October 13, for the improvement of certain roads at this place. Address Charles M. Todd, Supervisors' Clerk, *pro tem*, as above.

PIPE, BOILERS, ETC., Water Valley, Miss.—Proposals are wanted, no date specified, for furnishing pipe, boilers, pumps, etc., for water-works. Address Mayor W. A. Herring, as above.

VISIT OF THE FOREIGN ENGINEERS TO THE UNITED STATES.

THE New York meeting of the American Institute of Mining Engineers, which was held this week, was remarkable in several respects, having been not only a gathering of that body alone, but, in a measure, also of many members of the sister societies of civil, mechanical and electrical engineers to welcome to the United States visiting members of the British Iron and Steel Institute and of the Verein Deutscher Eisenhuettenleute. The meeting was of a decidedly international character, the foreign engineering institutions being largely represented, several hundred members being present.

The plan of having a meeting of the British Iron and Steel Institute in the United States is one of several years' standing and has been talked over a good deal, but its execution seems to have finally been hastened by the visit to Europe last year of the mining, civil and mechanical engineers' societies of this country. The simultaneous coming of the German engineers, who represent industries closely allied to those of the Iron and Steel Institute, adds to the importance of the gathering, and has helped to bring about an opportunity for at least a partial return of those courtesies which were extended so lavishly to the American engineers during their stay abroad. How well this return is to be effected can at present best be indicated by a brief review of the programme which has been mapped out by the American Committee of Arrangements and Entertainment.

Besides excursions on Tuesday and Wednesday, specially arranged for the ladies in attendance, there was an excursion up the Hudson River, by boat, on Wednesday afternoon, while for yesterday afternoon three others had been arranged to different points; one by boat up the East River to the Navy Yard, the De La Vergne Refrigerating Machine Company's Works, and to the Washington Bridge over the Harlem; another, by train, to the Tilly Foster Iron Mine and Electrical Separating Works; and the third, by train, to the Edison laboratory at Llewellyn Park, N. J. Invitations had also been extended to visit the Hudson River Tunnel and various noteworthy manufacturing establishments in the vicinity of New York.

To-day, the members and guests proceed, by special train, to Philadelphia; on Tuesday, October 7, to Lebanon and Harrisburg; and on Wednesday to Johnstown and Altoona, arriving Wednesday evening at Pittsburg, according to the programme of the General Reception Committee. At Pittsburg, two joint international sessions will be held by the Mining Engineers and the Iron and Steel Institute and their guests, for the reading of papers.

The general excursion will proceed from Pittsburg to Chicago, and at the close of the visit to Chicago will divide into two parties, going respectively north and south. According to the programme of the General Reception Committee, the northern excursion will visit the Menominee, Gogebic and Marquette iron ranges and the Lake Superior copper district, returning to New York *via* the Sault Ste. Marie Canal, the Sudbury (Canada) nickel and copper mines, and Niagara, while the southern excursion will go from Chicago to Birmingham, Shelby and Anniston, Ala., returning to New York *via* Chattanooga, Tenn., Middlesborough, Roanoke, Cripple Creek iron mines and Pocahontas coal mines, Luray, Va., and Washington. Both excursions will reach New York about October 28.

Considering the proceedings of the week just past, it was scarcely to be expected that much work would be accomplished at the various sessions in the way of reading and discussing papers. Of such papers there was certainly no lack, but the attractions of sight-seeing and unconventional social intercourse among the members were sufficient to keep all but a relatively small proportion away from the business sessions. The foreign visitors were naturally anxious to see all there was to be seen in and around New York, and the American engineers, ably assisted by a local committee of ladies, were correspondingly anxious to prove themselves agreeable and satisfactory guides. The slim attendance at the sessions, though unfortunate, was, therefore, not to the discredit of the papers. It is, moreover, not to be expected that the experiences in connection with the sessions next week will be remarkably different. However much the tendency may have been criticised to spend a large share of the time during engineering conventions in excursions to different points of interest, the fact remains that a good deal of information, not otherwise readily obtainable, is made available by this plan, and even in the present instance it is not likely that there will be any murmurs that time has been needlessly wasted.

So far as the foreign guests are concerned, it seems almost needless to say that they will not be permitted to leave the United States without having been given good opportunities to form reasonably fair impressions of the natural and industrial resources of the country.

RAPID TRANSIT IN CITIES.

SOME very interesting and valuable figures, illustrating the development of rapid transit in cities, are given in Census Bulletin No. 11, devoted to transportation, and just issued from the Census Office at Washington. Street railroads have never before been brought within the scope of the census statistics of transportation, and some peculiar difficulties were met with in collecting the figures. Of the 286 street railroads to which the statistics relate, having a total length of 3150.93 miles, thirteen with a total length of 135.75 miles had not made reports up to the time of publishing the bulletin, and the information in regard to them was obtained with approximate correctness from other sources. In several other cases the returns received were so imperfect that it was necessary to resort to approximations. Taken altogether, however, the work would seem to have been carried out with commendable attention to details and the published tables are, no doubt, the most reliable now existing. They show the growth of rapid transit facilities from 1880 to 1889, inclusive, in cities of the United States having over 50,000 inhabitants.

There are, in all, five tables replete with valuable data. Table I. gives the number of miles operated in each city during the years stated, and also the aggregate mileage of the 56 cities for each year; Table II. shows the increase and percentage of increase in the aggregate mileage of the different roads; Table III. the total mileage operated in each city on December 31, 1889, is subdivided so as to show the number of miles operated by each of the various kinds of motive power; Table IV. shows the percentage of total mileage operated by each kind of motive power on the same date; and Table V., finally, shows not only the total length of line in each city on December 31, 1889, but also how much of this line is laid with single and how much with double track. The length of all tracks, including sidings, is also given.

It appears, that of the cities considered, Omaha has made the greatest increase. Starting with 4½ miles of track in 1880, there are now nearly 45 miles. Denver has grown from 8 to 63½ miles; Minneapolis has increased to 42½ miles; Chicago, in the ten years, has laid 104 miles, increasing 129.6 per cent.; Philadelphia, which is near the bottom of the list, has added 34¼ miles, or 13.76 per cent. in the ten years. Of electric roads Boston has 49 miles, Scranton 23, Pittsburg 20, Omaha 23, and Cleveland 18. Denver has 29 miles of cable road, Kansas City 38, San Francisco 47, Chicago 24, St. Louis 20, Philadelphia 23. New York has 32½ miles of elevated roads, Brooklyn 24¼, and Kansas City 5⅛. Of surface roads operated by steam, Birmingham, Ala., has 60 miles, Kansas City 32½, Los Angeles, Col., 25¾; Nashville, Tenn., 20; Minneapolis 23; and San Francisco 13.

It is out of the question to reproduce all the tables here, but to the more particularly interested reader reference to them will prove instructive. As an illustration, however, of the extent to which the various kinds of motive power are in use we append Table IV.:

Motive Power.	Miles.	Per cent.
Animal power	2,351.10	74.62
Electricity	260.36	8.26
Cable	255.87	8.12
Steam (elevated roads)	61.79	1.96
Steam (surface roads)	221.81	7.04
Total	3,150.93	100.00

These figures tell their own story. Among the comparisons which the other tables make possible, it may be of interest to briefly state that the table giving the length of line in 1889, shows Philadelphia far ahead of all other cities. The length assigned to each of the leading five cities is as follows: Philadelphia, 283.47 miles; Boston, 200.86; Chicago, 184.78; New York, 177.10; and Brooklyn, 164.44. In the table, however, which gives the length of all tracks, we find that, as regards the position of Philadelphia, the table is reversed, and that New York rises from fourth to first place. The number of miles assigned to each city in that table is: New York, 368.62; Chicago, 365.50; Boston, 329.47; Brooklyn, 324.63; and Philadelphia, 324.21. The reason of these changes becomes clear by the statement that the length of double track in each of the five cities is as follows: Chicago, 176.05 miles; New York, 161.90; Brooklyn, 138.84; Boston, 104.54; and Philadelphia, 39.99 miles. From this it is seen to be a peculiarity of the Philadelphia roads, and, to some extent, of the Boston roads also, that the tracks usually occupy different streets in going to and from a terminus, instead of being laid upon the same street. The result of this is that roads in the cities named traverse a greater length of street in proportion to track length than in New York, Brooklyn or Chicago.

As to rapid transit facilities in cities of the United States generally, the statistics show that on December 31, 1889, 476 cities and towns had street railroads, and that the total number of these in independent operation was 807.

It is announced that Lieut. L. N. B. Wyse has obtained from the United States of Columbia an extension of the time for completing the Panama Canal, probably adding six years to the present concession, which ends in 1892.

STORAGE BATTERY STREET CARS AT PARIS.

Experiments with the working of tramways by electricity, says the London *Electrician*, are being continued in Paris by the Northern Company on the line between Levallois and Madeleine. Four cars are practically worked, and the Société Francaise d'Accumulateurs Electriques (Faure-Sellon-Volckmar), who supply the motive power at the rate of 3*d*. per car and kilometer, are of opinion that the traffic will be permanent. The motive power is furnished by Faure-Sellon-Volckmar accumulators, with double plates. The batteries are divided in 12 boxes, each containing nine elements coupled in series, 108 cells in all, and as each element weighs 15 kilograms, the total weight of the battery is 1,620 kilograms.

The 12 boxes are placed in cupboards in the corners of the car—four in front and eight behind. The connections are so arranged that the elements, when the boxes are fixed in their places, become automatically ranged in groups of three by three boxes behind each other, so that there are four groups in all of 27 elements ranged after each other. These four groups may be connected for work in four different ways, as at the Birmingham tramway. The various connections are effected by the aid of a commutator, consisting of a wooden cylinder, with contacts on the surface. The cylinder is turned by a handle. The electrical motor is of Siemens' construction, and situated below the car in front. The number of revolutions may be raised to 1,600 a minute, but under normal working it is 1,000. The power is transmitted to the wheels of the car through gearing, which reduces the speed in the proportion of 26 to 1.

The motor is reversed by the use of a double set of brushes. The cars weigh 3,500 kilograms, there being 1,600 kilograms of accumulators, and they carry 50 persons. During ordinary speed of 11 kilometers (6.85 miles) an hour the electrical work required is as follows: On level road, 4.3 h. p. (16 ampères × 200 volts); on incline of 1 in 100, 7.8 h. p. (29 ampères × 200 volts); on incline of 1 in 50, 11 h. p. (42 ampères × 200 volts). With a speed of 9 kilometers (5⅝ miles) an hour and an incline of 1 in 33, 12.3 h. p. (46 ampères × 200 volts) are required. On an incline of 1 in 25, 15.3 h. p, (57 ampères × 200 volts). Finally, with a speed of 5 kilometers (3 miles) an hour and an incline of 1 in 20 the force is 10.2 h. p. (38 ampères × 200 volts), and on an incline of 1 in 18, 10.75 h. p. (40 ampères × 200 volts).

JARRAH WOOD.

The last number of the *Kew Bulleton* contains a note on the properties and uses of the jarrah wood, a species of eucalyptus, native to Western Australia. The main difficulties in connection with its use in this country are the cost of freight for such heavy timber from Australia and its intense hardness, which makes it difficult for ordinary English carpenters' tools to work it. The tree which produces it grows generally to a height of 100 feet, and sometimes 150 feet. It is found only in Western Australia, extending over the greater portion of the country from the Moore River to King George's Sound, forming mainly the forests of these tracts. According to Baron Mueller, when selected from hilly localities, cut while the sap is least active, and subsequently carefully dried, it proves impervious to the borings of insects. Vessels constructed solely of it, have, after 25 years' constant service, remained perfectly sound, although not coppered. It has been tried at three places in the Suez Canal, and after having been down seven years, the trial samples were taken up in order that a report on their condition might be sent to Paris.

Under the head "The City House in the West," Mr. John W. Root, of the firm Burnham & Root, architects, of Chicago, Ill., contributes an interesting article to the October number of *Scribner's Magazine*. As implied in the title, the article concerns itself with one line of Western city architecture, and the reader will find, besides Mr. Root's well written account, a series of finely executed engravings illustrating the subject.

THE ARCHITECTURAL LEAGUE OF NEW YORK.

The next meeting of the League will be held on Monday evening, October 6, at the "Arena," No. 41 West Thirty-first Street. Dinner will be served at 6.30 o'clock. Mr. F. S. Dellenbaugh will speak on the subject of "Architectural Forms in Nature."

The Committee on Current Work announces that arrangements have been made with Mr. C. H. Blackall, of Boston, to read a paper on "Portuguese Architecture." at the November meeting.

MEETINGS OF ENGINEERING SOCIETIES.

The **American Society of Civil Engineers** holds its regular meetings on the first and third Wednesday in each month, at the House of the Society, 127 East Twenty-third Street, New York.

The **Boston Society of Civil Engineers** holds its regular meetings at the American House, Boston, at 7.30 P. M., on the third Wednesday in each month.

The **Western Society of Engineers** holds its regular meetings at its hall, No. 67 Washington Street, Chicago. at 7.30 P. M., on the first Wednesday in each month.

The **Engineers' Club of St. Louis** holds regular meetings in the club's room, Laclede Building, corner Fourth and Olive Streets, St. Louis, on the first and third Wednesdays in each month.

The **Engineers' Club of Philadelphia** holds regular meetings at the House of the Club, 1122 Girard Street, Philadelphia.

The **Engineers' Society of Western Pennsylvania** holds regular meetings on the third Tuesday in each month, at 7.30 P. M., at its rooms in the Penn Building, Pittsburg, Pa.

The **Engineers' Club of Cincinnati** holds its regular meetings at 8 P. M. on the third Thursday of each month at the Club rooms, No. 24 West Fourth Street, Cincinnati.

The **Civil Engineers' Club of Cleveland** holds regular meetings on the second Tuesday of each month, at 8 P. M., in the Case Library Building, Cleveland. Semi-monthly meetings are held on the fourth Tuesday of the month.

The **Engineers' Club of Kansas City** meets in Room 200, Baird Building, Kansas City, Mo., on the second Monday in each month.

The **Engineering Association of the Southwest** holds regular meetings on the second Thursday evening of each month at 8 o'clock, at the Association headquarters, Nos. 63 and 64 Baxter Court, Nashville, Tenn.

The **Civil Engineers' Society of St. Paul** meets at St. Paul, Minn., on the first Monday in each month.

The **Montana Society of Civil Engineers** meets at Helena, Mont., at 7.30 P. M., on the third Saturday in each month.

The **Civil Engineers' Association of Kansas** holds regular meetings on the first Wednesday in each month at Wichita, Kan.

The **New England Water-Works Association** holds quarterly meetings in Boston at Young's Hotel.

The **Canadian Society of Civil Engineers** holds its regular meetings on each alternate Thursday, commencing with the 9th of October, at the House of the Society, 112 Mansfield Street, Montreal.

The first fall meeting of the Engineers' Club of Philadelphia will be held at the Club House to-day at 8 o'clock P. M.

The convention of the American Institute of Architects will be held in Washington, D. C., beginning on October 22, and continuing until the business has been completed. Papers on art, construction and kindred topics are solicited from the members. The titles of such papers should be forwarded to the Committee of Arrangements by October 8, so they can be arranged for in the Order of Proceedings

The corner stone of the new Chamber of Commerce building at Boston, Mass., was laid on September 29.

OBITUARY

William Johnson, architect, died at Brooklyn, N. Y., last week, of a complication of diseases and old age.

Frederick Billings, ex-President of the Northern Pacific Railroad, died on September 30, in Woodstock, Vt., from the effects of a paralytic stroke and advanced age.

Stephen P. Perkins, an old and well-known builder, of Woodbridge, Conn., died suddenly on September 27. Among numerous prominent buildings which Mr. Perkins constructed are the Yale Art School, the Peabody Museum at Yale, the Alumni Hall on the campus, Yale Divinity School, North Sheffield Hall of the Scientific School, the Church of the Sacred Heart, and the old railroad station at Hartford.

PERSONAL.

Willis W. Casey, C. E., was recently appointed Deputy County Surveyor at Joliet, Ill.

Mr. A. P. Cutting, architect, of Worcester, Mass., has just returned from a two months' trip in Europe.

Hon. John Bogart, State Engineer New York, and Secretary American Society of Civil Engineers, arrived from Europe on September 29.

Arthur H. Williams, a prominent contractor of Camden, N. J., was killed at a Camden and Atlantic Railroad crossing on September 30.

At the New York meeting of the British Iron and Steel Institute, Sir Frederick Abel, C. B., F. R. S., of London, was chosen to succeed Sir James Kitson, Bart., as president for the ensuing year.

Henry W. Cannon, President of the Chase National Bank, has been appointed by Mayor Grant of New York, to fill the vacancy in the Aqueduct Commission caused by the death of Walter Howe.

Among other prominent members of the British Iron and Steel Institute now at New York, are: Sir James Kitson, Bart., Sir John G. N. Alleyne, Bart., P. C. Gilchrist, E. P. Martin, E. Windsor Richards, G. T. Snelus and J. S. Jeans.

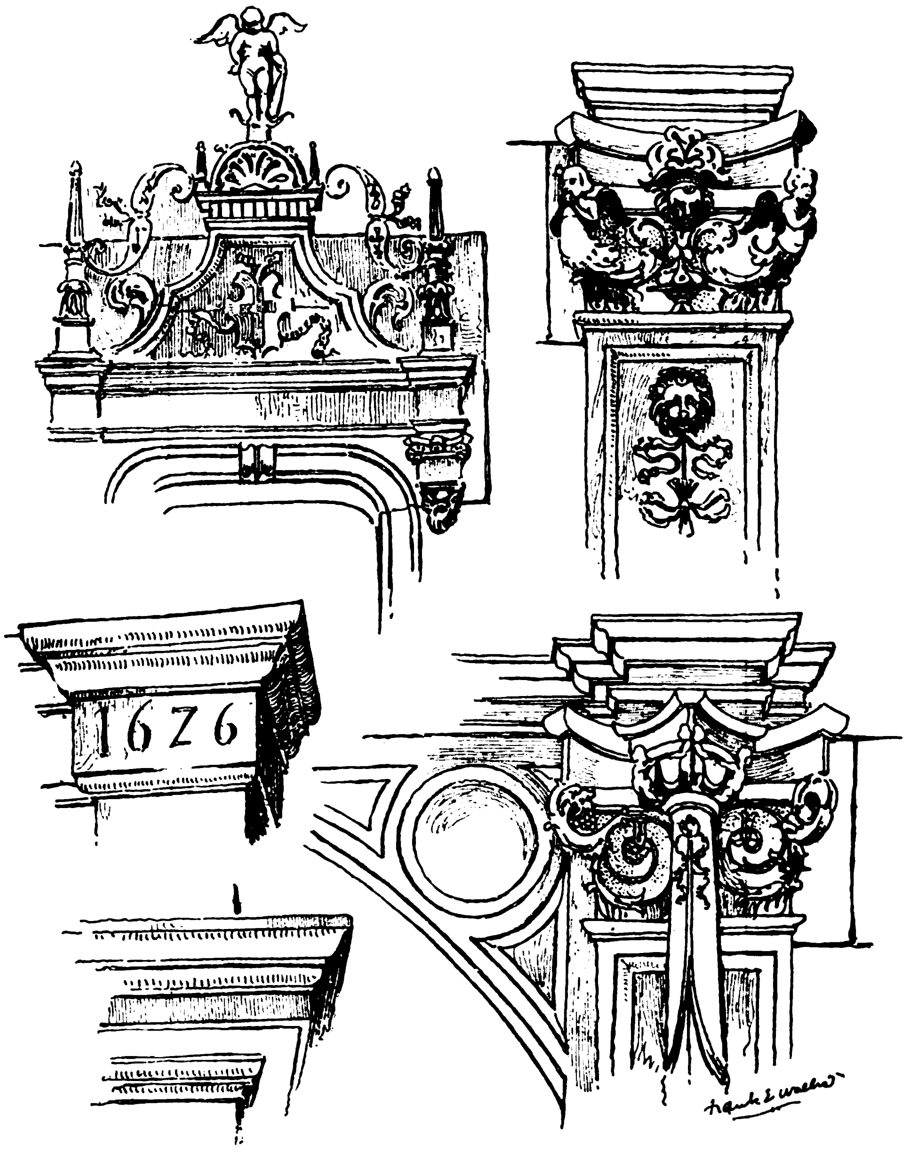
ENGINEERING SOCIETIES.

A MEETING of the Western Society of Engineers, of Chicago, was held on Wednesday, September 3, at 8 o'clock P. M., President L. E. Cooley in the chair, and some 80 members and visitors present. The minutes of the previous meeting were disposed of and the Secretary made a report of the meeting of the Board of Directors.

The following members were elected: Rudolph B. Bourland. C. F. Theodor Kandeler, Edward L. Abbott, Charles H. Miller.

The following applications for membership were received: Charles E. Hopkins, Charles V. Weston, Theodore Starrett, Jacob A. Harman, Henry E. Gamble, Ira Smith Dunning, L. C. B. Holmboe, Charles J. Morse, William E. Miller, Ridley H. Lawrence, Harold A. Boedker.

The special topic of the meeting was the World's Fair Site.



SKETCHES FROM SHOOTING LODGE OF FRANCIS I., PARIS.

A REGULAR meeting of the American Society of Civil Engineers was held October 1, with President W. P. Shinn in the chair. Regular business was transacted and invitations read to join the meetings and excursions of the Mining Engineers and their guests from Germany and England, who are now in convention, with headquarters in New York.

The Secretary announced the recent deaths of the following members of the Society: W. H. Atwood, Cleveland. O.; M. S. Belknap, Savannah, Ga.; Theodore Allen, So. St. Louis, Mo.; C. Ackenheil, Elizabeth, N. J.; J. L. Gillespie, St. Paul, Minn.; and J. F. Wells..

A paper by J. Fras. Le Baron, M. Am. Soc. C. E., on "The Fallacy of the Contract System of the U. S. Land Surveys," was read by the Secretary, and discussed by R. L. Harris. Adjournment was followed by the usual light collation.

The following candidates were elected:

As Members.—Guilliaem Aertsen, Manager Latrobe Steel Works, Latrobe, Pa.; William Sinclair Bacot, Water-works Engineer, New York City; George Irving Bailey, now Assistant Engineer in charge of New York State canal work, Albany, N. Y.; Charles Backus Ball, Assistant Engineer Sewer Division, Engineer Department of District of Columbia, Washington, D. C.; Percy Mortimer Blake, at present completing the Andover (Mass.) Water-Works, and engaged as Expert and Consulting Engineer, Hyde Park, Mass.; John B. Bott, Principal Assistant Engineer Maryland Central Railroad and Baltimore Belt Railroad, Baltimore. Md.; Albert Newman Connett, Principal Assistant in charge of construction Baltimore Traction Company, Baltimore, Md.; Herbert Franklin Dunham, Chief or Consulting Engineer City Water Board, Wheeling, Va., reconstruction of water-works, Massillon, O., and new works for Coshocton, O.—address, Cleveland, O; Oscar Anton Frederik Saabye, Resident Engineer in charge Construction Maintenance of Way, Norfolk and Western Railroad, Roanoke, Va.; Archibald Alexander Schenck, Chief Assistant Engineer New York Central and Hudson River Railroad, New York City; Hood Tucker, Resident Engineer Charleston, Cincinnati and Chicago Railway, White Story, Tenn.

As Associates.—Patrick Henry Griffin, General Manager St. Thomas Car Wheel Company, Canada Iron Furnace Company, and President New York Car Wheel Works, Buffalo, N. Y.

As Juniors.—Robert Augustus Cummings, Assistant Engineer Norfolk and Western Railroad, Roanoke, Va.; Charles Robert Beltes, Assistant in office of Charles B. Brush, M. Am. Soc. C. E., in charge of many survrys and improvements, etc., Hoboken, N. J.; William Chauncey Hawley, Assistant to Chester B. Davis, M. Am., Soc. C. E., Chicago, Ill.; Ezra Booth Naylor, Assistant Engineer New York Central and Hudson River Railroad, New York City; Homer Reed Stanford, Assistant Engineer with Johnson and Flad, Members Am. Soc. C. E., St. Louis, Mo.; Richard Collier St. John, Assistant to Rudolph Hering, M. Am. Soc. C. E., Princeton, N. J.

THE most powerful artificial light in existence is the electric lamp in the lighthouse of St. Catherine's Point on the Isle of Wight, England. The ordinary light is equal to 3,000,000 candles, but a light of 6,000,000 candle-power can be and has been obtained.

NEW YORK MEETING OF THE MINING ENGINEERS.

THE fifty-seventh meeting of the American Institute of Mining Engineers was held at New York during the week just closing, and was made more particularly noteworthy by the fact that it was attended by a large number of members of the British Iron and Steel Institute, and of the Verein Deutscher Eisenhüttenleute.

The first session was held at Chickering Hall on Monday afternoon and was opened by brief introductory remarks by James F. Lewis, Chairman of the Local Committee, and Abram S. Hewitt, President of the Institute. The first paper was by James C. Bayles, on "Explosives from Unknown Causes," and is referred to more at length elsewhere in this issue. It was followed by brief presentations of the following papers, the session being adjourned at an early hour in the afternoon.

"Magnetic Concentration at the Michigamme Iron Mine, Lake Superior," by John C. Fowle; "Ore Dressing by Electricity at the Tilly Forster Iron Mine," by F. H. McDowell; "Magnetization of Iron Ore," by Clemens Jones; and "The Ball and Norton Monarch Magnetic Separator," by C. M. Ball

The evening session on Monday was devoted to an exhibition of lantern views of "The Iron Mountain Mine," by Professor W. B. Potter, of St. Louis, and to an interesting review of "American and Foreign Practice with the Diamond Drill," by W. F. Durfee, of Birdsboro, Pa. Extracts from the latter are published in another column.

The Tuesday morning session began with a paper on "Electric Power Transmission in Mining Operations," by H. C. Spaulding, of Boston, Mass. It was followed by other papers on "Amalgamation at the Comstock Lode, Nevada," by A. D. Hodges, Jr., and "Notes on the Excavation ot the New Croton Aqueduct," by J. P. Carson. Portions of this are given in this issue.

The papers of the Tuesday afternoon and evening sessions were, in the main, of a mining and metallurgical character. They included one by R. M. Daelen, of Dusseldorf, Germany, on "Recent Improvements in German Steel Works and Rolling Mills;" one by S. T. Wellman, of Thurlow, Pa., on "Machinery for Charging of Heating and Melting Furnaces;" another on "Pneumatic Hoisting," by H. A. Wheeler, of St. Louis; one by E. R. Walker, on "The Walker Anti-Vibration Regulating Shutter or Slide for Guibal or other Inclosed Fans;" "Coal Mining in Oregon," by R. H. Norton; "The Resources of the Black Hills and Big Horn Country, Wyoming," by H. M. Chance, and "The Copper Resources of the United States," by James Douglas, Jr. Magic lantern views were also given in the evening to accompany the paper on "The New York Aqueduct," by A. Fteley.

A large number of papers besides these could be presented by title only.

On Wednesday, Thursday and Friday mornings there were sessions of the British Iron and Steel Institute, the remaining portions of the week being given up to a number of local excursions. To these and to the programme of the next few weeks further editorial reference is made in this issue.

THE BERLIN ELECTRICAL WORKS.

A VERY interesting application of electric transmission of power is to be found at the works of the Allgemeine Electricitats Gesellschaft, at Berlin, Germany, where all the machines for building steam engines, dynamos, electromotors, electric elevators, etc., are driven by electromotors. *Kuhlow's German Trade Review* describes the plant as follows:

Two compound steam engines of 100 horse-power each are coupled direct to suitable large dynamos of 110 volts pressure, which supply the electric current both for lighting purpose and for the electric motors. There is no need for belting or any other form of mechanical transmission. A net-work of cables supplies the energy into the smallest, and otherwise quite inaccessible corners, and renders it possible to alter the position of the different machines according to the special purpose. This is of great advantage for very heavy and large pieces to be shaped or worked at, since the tool may be brought to the work piece, and not *vice versa*. Although part of the energy expended is wasted in the primary dynamos and in the electromotors, it is stated that this waste is far below the loss that would be caused by a mechanical transmission plant requisite for this factory. There is, besides, another drawback of mechanical transmission. The plan of the buildings, is, to some extent, dependent upon the general disposition of the belts and pulleys, while with the electric transmission of power every space of the building, no matter how this was designed, can be easily reached, without complicated belting, friction, and cogwheel apparatus, and the control of the bearings, couplings, and the dangerous management of belting is entirely avoided. As to the working expenses it must not be overlooked that as each motor may be used independently from the others, considerable saving of running power can be obtained, because it never occurs, as with the mechanical transmission, that for only one small working machine a very heavy countershaft, with all its supplements, must be run idle. The lighting of the workshops is interesting, and is obtained by 85 arc lamps and 300 16-candle lamps; the former are suspended only 7 feet from the ground, but inclosed below by a parabolic reflector, which throws the rays up against the whitewashed ceilings and walls, so that there is a very splendid day-like illumination, and no workman is compelled, in order to see the details of his job, to approach the lamps.

THE papers and plans connected with the scheme of making Paris a seaport have been deposited at the Hotel de Ville for public inspection. They are to be accessible there until the 15th of November, so that they may be carefully examined. The proposed canal from Rouen to Paris is to have a length of 180 kilometers and a depth of 6 meters. The docks are to be constructed between St. Denis and Clichy. The expense is estimated at 135,000,000 francs. The duration of the voyage from Rouen to Paris will be 17 hours, and the dues 6 francs 50 cents. a ton going and coming.

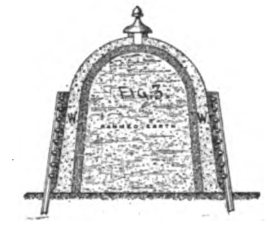
CONCRETE HOUSES IN INDIA.*

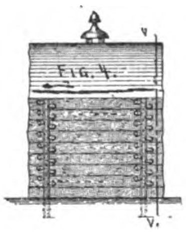
THE excessive cost of housing the native lower staff of Indian railroads has caused the adoption of concrete dwelling houses for this occupation, and the following advantages are claimed for them: Ease of erection, almost universal local supply of materials; small amount of skilled labor and supervision required; cheapness (one-half cost of masonry): durability, imperviousness and coolness.

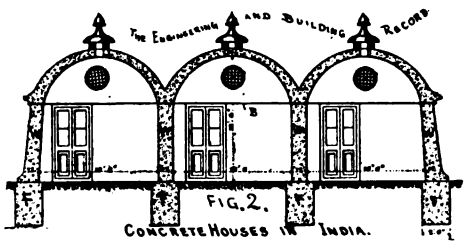
Figure 1 is a plan of a house; F F, etc., are lines of foundation footings; W W, etc., the concrete walls; P P, etc., the brick partitions, and B B, etc., wrought-iron tie rods. Figure 2 is a vertical section at Z Z, Fig. 1; Fig. 4 is an elevation at X X, Fig. 1, and Fig. 3 is a section at V V, Figs. 1 and 4.

Centering and Aligning.—This can be cheaply and expeditiously done by simply raising a mound of earth the whole length, and in contour, of the inside section of the building, in rammed layers, and having the outer surface dressed off with clay. After construction the earth is easily removed through the doorways. The outer surface of the concrete is supported either by a clay wall 1 inch thick, banked with earth, or by a framework of rails and sleepers or boards, Figs. 3 and 4, attached, and, as is preferable, and as cheap, where several blocks are to be erected, the centering can also be put up of the same.

In erecting the centering, it will be found useful in setting out the work, and for purposes of check afterwards, to put up light poles with cross-piece, from which to stretch aligning cords to pegs in the ground; this at either end of the block. A light template is required for he curved roof, Fig. 5.







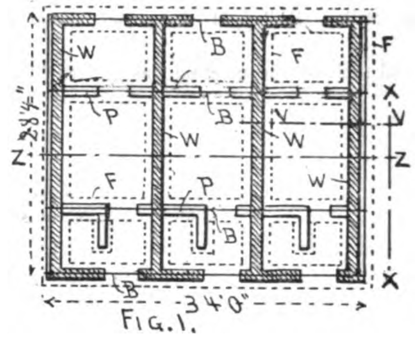
THE ENGINEERING AND BUILDING RECORD
B
FIG. 2.
CONCRETE HOUSES IN INDIA.

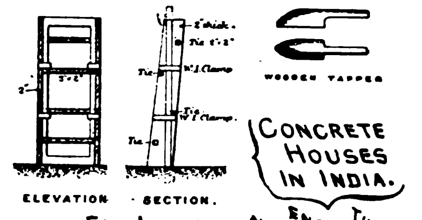
Methods of Construction.—1. After the concrete foundations have been rammed solid, the centering and outer framework should be erected, and the door-frames fixed in position. The frames to have projecting pieces 6 inches down into the concrete, and 3 inches upwards to fit into sockets in the stone lintels. They should also have temporary flanges, Fig. 6, clamped on either side, to retain the concrete walls during construction. The stone lintels should be as light as possible, say 1½ inch thick, and not overhang more than 6 inches, being laid nearly horizontal across, and bedded 12 inches in the concrete at either end. The lintels should be kept ½ inch clear of the top of the door-frame to allow for settlement, and be supported till the concrete sets. The lintels can be plastered with a slope on the top to shed rain.

2. The concrete should be laid in a 6-inch layer, and well consolidated with wooden hand-tappers; the top surface should then be slightly picked up, preparatory to laying the next course, and so on. The tie-rods, fitted with their large washers, 6"x6"x¼", and cotters, or roughly forged heads, are laid in position about one inch above the springing of the arch, the concrete being carefully packed against the washers. The walls are given a slight batter to meet the thrust of the arch, so that tie-rods are not necessarily required, but are simply intended to lend additional stability to the structure.

3. The concrete in the arch should also be laid in 6 inch courses, and carefully beaten in the direction of the thrust, and with a face parallel to the radius; a movable board with slightly curved face, and which can be adjusted as required, can be used to retain the outer surface while being consolidated. Usually the centering, etc., can be removed in about 15 days after completion of the concrete, the outer surface smoothly, and the inner roughly, plastered, and the partition walls dividing off the units erected of sunburnt brick, or country burnt brick set in clay mortar. The interior can then be whitewashed. This method of putting in the partition walls last, and of such material, is found to save the concrete from cracking over the walls, as it usually does on other works where the walls are erected first, expansion or contraction being thus interfered with. Another advantage is, that the centering can be more easily placed as well as removed.

Concrete.—Broken stone, hard brick or kunkur cubes, not exceeding 1½-inch in foundations, and ¾-inch in superstructure.





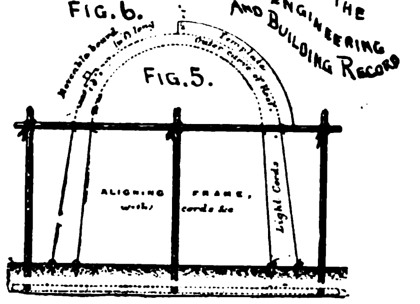


FIG. 6.
THE ENGINEERING AND BUILDING RECORD
FIG. 5.
ALIGNING FRAME, with cords &c
Light Cords

Mortar, composed of 2½ parts of sand or soorki to 1 part of lime, thoroughly ground for say six hours in a bullock-power mill.

The above to be well worked up together in the proportion of 1 part of mortar to 2 parts of metal.

STORAGE BATTERY TRACTION.

THE *Electrical World*, in a recent issue, very aptly remarks:

> "There seems just now to be a marked increase of interest in the use of the storage battery At least half a dozen varieties of electric cars thus equipped are being thoroughly tried in an experimental way, aside from the three or four roads that have such a system in regular operation. The cars on the Fourth Avenue line in this city are growing to be a conspicuous part of its equipment. By all means let the good work go on until something thoroughly practical is evolved. There is a good time coming in urban electric traction, and it behooves electric railway engineers to see that it is not unduly delayed by the advent of the cable abomination. This probably will soon obtain a resting place on Broadway, and will manage to set its fangs into other streets unless its attacks are vigorously combatted."

A WONDERFUL example of erosion is shown in an illustration accompanying Professor Michie Smith's article on the eruption of Bandaisan in the *Proceedings of the Royal Society of Edinburgh*, Vol. xvii., page 70. The valley there depicted was produced by the erosive power of a small stream within the short space of ten months. Its depth, when Professor Smith visited the neighborhood, was 80 feet, and in some places little short of 150 feet.

THE British Association at its last meeting recommended the adoption of a new value for the ohm, the unit of electrical resistance. The proposed B. A. ohm is 1.0028 times the legal ohm of 1884, and consequently resistances measured in legal ohms are numerically too great by a trifle less than three-tenths of 1 per cent.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

No. C.

(Continued from page 213.)

ERECTION OF THE HOOGHLY JUBILEE BRIDGE, INDIA*.

PART I.—PIERS, CAISSONS, ABUTMENTS AND VIADUCT.

At the site of the Jubilee Bridge the River Hooghly is 1,200 feet wide at low water, and the crossing for two railroad tracks is effected, Fig. 1, by one 360 feet 6 inch cantilever span, and two connecting spans, each 420 feet, together with brick arch viaduct approaches at the Hooghly and Naihati ends, of 3,280 feet and 450 feet, respectively.

The river bed on the right side is 66 feet deep below datum, or mean sea level. The right bank is well above the highest flood level. On the left side the river is comparatively shallow, and there is a wide stretch of low ground which is inundated in the flood season. The deep channel on the Hooghly side is scoured out to the clay by the flux and reflux of the tide, while the depth on the left side of the river varies with the movement of the sand or silt which there forms the bed of the river. In the freshets a variable thickness of silt is displaced. When the floods are strong the river bed is removed to a depth of 29 feet or more below datum.

The tides vary from mean sea level or a foot below in the dry season, to 20 feet above in the freshets; the maximum velocity of the tides is 4½ miles per hour when the flood tide comes in with a strong bore, and 5¾ miles an hour on the ebb tide in the freshets.

"The Engineering and Building Record"

River Piers.—The site of the river piers is in about 27 to 30 feet of water at low spring tides in the dry season; the bed of hard yellow clay is met with at a depth of about 89 feet below datum at this part of the river, and the piers had to be sunk through about 60 feet of silt to reach the clay. The piers are 66 feet long, up and down stream, by 25 feet wide, with semicircular ends and flat sides. To sink these, two wrought-iron caissons, 108 feet high by 66 feet long by 25 feet, with semicircular ends, and each weighing 453 tons, were provided. The caissons (Fig. 4) were divided into three excavating chambers open from top to bottom, by two transverse compartments A A, each 15 feet wide on the longitudinal axis of the caissons (Fig. 5). These compartments afforded the buoyancy necessary for floating the lower portion of the caissons from the shore, where they were built, to the site of the piers, and until they reached the bottom of the river. The semicircular ends of the caissons were strengthened by horizontal shelf plates 3 feet broad, at vertical intervals of 4 feet, the space between these being filled with brickwork as the caisson went down. For a height of 36 feet above the bottom of the caisson, the central chamber also had two lateral buoyancy compartments, which contributed to the stability of the caisson while afloat, though they reduced the area of the central excavating chamber to 10 feet by 17 feet, while the end chambers were semicircles 19 feet in diameter. In the upper portion of the caisson the lateral compartments were replaced by shelves 3 feet broad at vertical intervals of 4 feet. The combined horizontal area of the three chambers was 480 square feet, being 32 per cent. of the total area of caisson. To facilitate sinking through the river bed the lower portion of the caissons and of the transverse compartments was built with internal inclined surfaces, extending from the bottom of the caisson to a height of 12 feet. The bottom of the caisson is an angle iron 5"x5"x⅝", which, with the vertical skin plate and 3'x⅝" external stiffening plate, forms the cutting edge; the angle bar was filled by beveled timber inside, so that there was no horizontal surface at the bottom of the caisson. The wedge spaces between the internal inclined plates and outer vertical skin of the caisson were filled with cement concrete. The lower 16-foot length of each caisson was riveted up complete on the river bank, and launched on ways laid for the purpose, and when afloat it drew 9 feet of water. The upper portion of the caisson was built up in rings or zones, each 4 feet high and weighing 15 tons; these were connected with the completed portion of the caisson by internal 3½"x3"x$\frac{7}{16}$" angle bars, and ⅞-inch rivets, 3-inch pitch. The skin or outer plate of the caisson was ⅝-inch thick for a height of 44 feet, ½-inch thick for a further height of 32 feet, above which it was ⅜-inch thick.

Pontoons.—To afford a working platform for men and material, and to enable the caissons to be pitched correctly in position, two pontoons (Figs. 2, 3 and 4) were built of $\frac{5}{16}$-inch and ¼-inch plates, riveted to 2"x3" longitudinal angles 17 inches apart on 3½"x2½" transverse angles that were spaced 9 feet centers, and had interior bulkheads, a longitudinal one, B, in the center, and two transverse ones, C C, that were 72 feet apart. (These really coincide, in Fig. 2, with the trusses F F, but are there moved aside to show separately). They were built at the works on the river bank, and were launched sideways on ways laid under the transverse bulkheads, with a length of 75 feet overhanging at each end. The weight of each pontoon was 151 tons. The pontoons were equipped with powerful capstans, one at each end of each pontoon, or four in all, besides bollards, fair leaders, etc.

The pontoons were connected together by means of an intermediate iron platform D, level with the decks, also by an overhead staging constructed of old rails connected by bolts and castings; the two main trusses F F, of this staging, were fixed to the decks of the pontoons immediately over the transverse bulkheads, and therefore 72 feet apart from center to center. The pontoons were also connected by auxiliary trusses (E E, not showing in Figs. 2 and 3) nearer to the ends, the object being to preserve the decks in one plane. The main trusses were connected at the top by 27 girders, G G, etc., at intervals of 5 feet from center to center, below which were suspended three transverse railways, H H H.

When the pontoons were moored in position at the center of the bridge, there was a clear space of 4 feet 6 inches between the gunwales of the pontoons and the sides of the caissons as moored at the sites of the piers. The overhead transverse railways commanded the centers of the caissons, so that material brought into the dock between the pontoons on an iron punt could be lifted by crab winches traveling on the overhead rails, and deposited on either caisson or on the deck of the pontoons. This arrangement, coupled with double sets of excavating gear, enabled work on both caissons to be proceeded with simultaneously. One pontoon contained the steam power and pumps for excavating earth from the caissons, the other the steam power for driving the boring gear. The pontoons were cross-moored by four 3-ton anchors with 1¾-inch chain cables adjusted by chain tackles, by which a considerable strain was always kept on the moorings, the rise and fall of tide being allowed for by the long sweep of cables; thus moored, the pontoons kept exactly in position without drifting or being otherwise affected by the tides.

The lower 16 feet of the caissons were towed at slack water into position alongside the pontoons. The caissons were moored by means of girdle or bridle chains, suspended round them at a height of 10 feet above the cutting edge by rope lashings passing through cast-iron pipes bolted to the inside of their skin, in which holes were cut to allow lashings to pass through the pipes; by this arrangement when the caissons were pitched the lashings could be cut by the diver and the girdle chains removed, and there was no external projection to impede the sinking of the caissons through the earth.

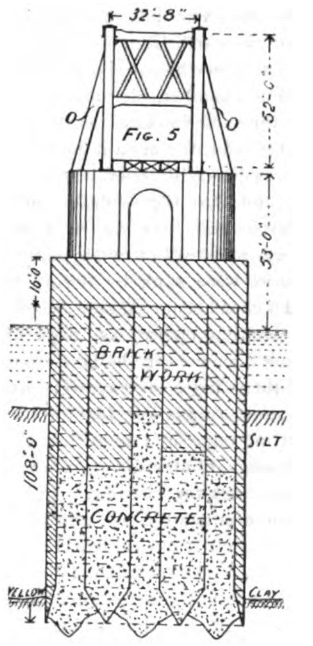

Fig. 5

HOOGHLY BRIDGE

The bridle chains of the caissons were connected by 1-inch chain tackles to up and down stream moorings, 3-ton anchors and 2-inch chain cables for adjusting the upstream and the down-stream position of the bottom of the caissons. Breast moorings of a lighter description for adjusting the lateral position of the caissons at the bottom were also used. It was necessary to hold the caissons by moorings near the bottom, as on account of the great grip of the tides on the open botton and transverse partitions of the caissons it would have been impossible to control them, when drawing over 30 feet of water, merely by topside tackle.

The sinking of the caissons through the water was effected by the weight of additional caisson rings, brickwork between the shelf plates of the semicircular ends, and concrete deposited in the buoyancy compartments. As the cutting edge approached the bottom of the river care had to be taken that it did not ground at low water. A sufficient height or free board of caisson having been built up to allow for sinking into the river bed and for rise and fall of the tides, the caisson was finally pitched by admitting water into the buoyancy compartments by means of syphons. As the caissons were sunk through the bed of the river the buoyancy compartments were filled with concrete of Portland cement and stone to the level at which it was safe to bale them dry, after which they were filled with solid brickwork affording weight for sinking them through the river bed

---

*Condensed from a paper by Sir Bradford Leslie, K. C. I. E., M. Inst. C. E., published in the Excerpt Minutes of Proceedings of the Institution of Civil Engineers. Vol. xcii.

One day, just after all hands had left work, the No. 1 caisson on the west side of the river, which was afloat ready for pitching, drawing 32 feet of water, and weighing 750 tons, was caught by the bore at an angle with its axis. The great pressure carried away the chain-lashings by which the top side of the caisson was secured to the pontoons ; this, and probable dragging of the bottom breast moorings, allowed the caisson to cant still more across the tide, and the enormous strain then carried away the chain tackles of the up and down stream moorings, and all the bollards and holdfasts on the pontoon decks, tearing to pieces the wrought-iron blocks, in which the 1-inch chain tackles wererove. The caisson was carried on the bore nearly ½ mile up the river and grounded across the stream, but on tolerably hard bottom. Fortunately the tide which did the damage was not the highest of the springs. When it slackened a barge was secured alongside, and the caisson was lightened by the removal of about 40 tons of cement brickwork, and with the assistance of strong warps hauled on by steam anchor barges suitably moored, and with the help of the bridge steam tender the caisson was dragged off the bank and floated at high water the next day. All the pontoon gear and ground moorings of the caisson being broken and lost, it could not be moored in position again. So it was temporarily moored by ropes made fast to trees on the river bank, and also by anchors till the dead neap tides, when it was towed out at slack water into position, and, the buoyancy compartments being filled by the syphons, was successfully deposited correctly in its permanent site.

Immediately a caisson was pitched the tide began to undermine it by scouring away the river bed outside, so that it was necessary to lose no time in starting to sink it by removing the earth from the inside. The dredging of the earth was done by special boring gear, one set in each excavating chamber, identical in principle, and, indeed, almost the same in detail as that used at the Gorai Bridge* in 1868–69, the main differences being that the boring gear was driven by steam instead of by air pressure or turbines, and that the syphons through which the earth was discharged into the river were charged by Körting's ejectors instead of by air pumps. Through the silt the caissons were sunk by boring heads 10 feet in diameter. To check scour outside, when it threatened to overtake the sinking operations, bags filled with dense black clay were deposited in the holes scoured out ; many thousands of these bags of clay were used. It was not safe to use stone rubble for fear of its working down under the cutting edge and impeding the sinking of the caissons ; the bags of clay did occasionally so get drawn in, but did not check the sinking. On one occasion the scour so far undermined the No. 2 caisson when it was 60 feet high, as to cause it to cant over to an angle of 1 in 8, and communication was established between the external water and the north boring compartment. The condition of the caisson was precarious. Heavy mooring anchors were laid out and connected by chain and rope tackles "luff upon luff" to the top side of the caisson, so that an estimated strain of 200 tons was exerted tending to right the caisson ; then by boring steadily in the chambers which were water-tight the caisson gradually righted, the tackles being constantly set up to keep the maximum strain as the caisson came over. The righting of this caisson shifted the position of the cutting edge slightly, so that the caissons are really 120 feet 10 inches apart instead of 120 feet 6 inches as originally pitched.

When the caissons got down to the hard yellow clay they stood firm on the cutting edge and did not penetrate it. The 10-foot holes excavated 8 feet in advance of the cutting edge, which were sufficient in sinking through the silt, had no effect. The boring gear had then to be lifted out of all the compartments, and two of the arms of each boring-head extended, so that they excavated holes 14½ feet in diameter, and, in fact, to a certain extent undercut the transverse compartments. The excavation of these large holes in advance of the cutting edge caused the clay to break in and the caisson to sink. When the cutting edge was far enough into the clay to make it safe to remove water from the caisson, the level of the water inside the excavating chambers was lowered 24 feet by special pumps, which increased the effective weight of the caissons by 700 tons and helped to sink them through the clay. The caissons were thus got down until their cutting edges were over 100 feet below datum, at which depth, being firmly embedded 10 or 12 feet in the solid clay, further sinking was stopped, and the excavating chambers were filled to a height of 46 feet below datum with concrete of Portland cement and broken stone, and above that level with solid brickwork, Fig. 4. The concrete was lowered through the water in iron boxes with four inclined bottom leaves, or flaps, hinged to the sides and released by the disengagement of a central bolt from the lifting-chain ; in this manner the concrete was deposited with very little disturbance and set very hard. Anchor-castings and sixteen 3-inch bolts, 24 feet long, for holding down the steel standards which carry the cantilever girders, are built into the upper portion of brickwork of each caisson.

The total dead-weight of one pier, including the steel standard and superstructure, is 12,567 tons, and the maximum moving load, consisting of two trains weighing one ton per lineal foot, is 1,320 tons, or together 13,887 tons; deducting the frictional support of the river bed on the surface of the caisson at 5 cwt. per square foot, or say 2,500 tons, the pressure on the base of each pier is 11,387 tons, or at the rate of 7 5 tons on the square foot. The normal pressure of earth and water at the same depth is 4.5 tons on the square foot.

To protect the piers from scour, since they have been sunk about 40,000 cubic feet of heavy stone rubble, averaging 2 or 3 cwt. each stone, has been deposited round each pier, and more will be added if required; but the large-sized rubble appears to be very effective in resisting scour.

The steel standards or pedestals, are simply vertical cellular structures, 30 feet high, of plate and angle-bars riveted together and secured to the brickwork of the piers by holding-down bolts and anchor-castings. These standards weigh 205 tons each, and carry the cantilever girders at a clear height of 53 feet above datum ; being slightly elastic they allow for the expansion and contraction of the girders in the span of 120 feet 6 inches between the river piers.

ABUTMENTS.

On the Hooghly side, where the deep channel runs, the bank is of stiff clay that resists the action of the water. Theabutment on this side was founded by sinking an iron curb 65 feet long by 28 feet wide by 8 feet deep. The curb had two cross partitions dividing it into three excavating chambers, open at top and bottom. The curb was, in fact, the taper shoe of the block foundation of the abutment; it was of sheet iron, ¼ inch in thickness, strengthened by gussets. The outsides of the curb were vertical and the inner sides inclining inwards from the cutting edges at an angle of 60 degrees; both sides of the inner transverse partitions were inclined. The curb was filled with concrete, on which the brickwork of the abutment was built, the sides of the excavating chambers being corbelled over until their size was reduced to 12 feet by 6 feet. To prevent dislocation of the brickwork during sinking, it was connected with the curb by a framework or crating of angle-bars, vertical and horizontal, securely riveted to the gussets of the curb. When sufficient weight of brickwork was built, the curb was sunk through peat and blue clay, additional brickwork being added as weight was required, until it finally rested 4 feet in the hard yellow clay at a depth of 34 feet below datum. This block foundation was excavated by hand, as but little water leaked in, which was easily removed by baling. When the curb had reached the desired depth, the excavating chambers were filled with concrete well rammed and brickwork. The neat work of the abutment started upon the block foundation at the level of 10 feet above datum.

The Naihati abutment was founded on a similar sheet-iron curb to that used on the Hooghly side ; but being pitched in sand, or rather silt, through which the water percolated, the soil had to be removed from the excavating chambers by Bull's dredgers worked by steam winches, the weight necessary for sinking being imposed by building up brickwork on the curb, leaving openings 12 feet by 6 feet for excavating from the three chambers. When the cutting edge of the curb reached 50 feet below datum the abutment began to hang by side-friction, and notwithstanding the addition of as much weight as possible, the quantity of stuff removed by dredging greatly exceeded the net displacement of the depth sunk, multiplied by the area of the curb. This drew in the soil from the outside, disturbing and cracking the surrounding earth for a distance of 100 feet on the land side of abutment ; however, it was finally sunk through the river silt till the bottom of the curb was 73 feet below datum, or 84 feet below the river bank. The excavating chambers were then filled with Portland cement and broken stone concrete to the level of 33 feet below datum, after which ordinary brickwork was used.

APPROACH VIADUCTS.

The approach to the bridge is by an arched viaduct of brickwork. The total length of viaduct through the town of Hooghly is 3,280 feet, of which a length of 450 feet adjoining the bridge was specially designed for the erection of the girders of the main side span on its spandrel walls. The extreme width of this viaduct at top is 37 feet 9 inches, and the piers are 15 feet apart from center to center, the clear span of the arches being 10 feet 10 inches. The foundations of concrete are spread over a large area, and the whole structure was made very massive, to sustain the severe strains to which it was subjected in the erection and launching of the girders of the main side spans.

A similar approach viaduct, 450 feet long, was erected on the Naihati side of the river ; on this side the height from ground level to the rails is 43 feet. The foundation of the greater portion of the viaduct consisted of a layer of concrete at a depth of about 8 feet below ground level, with an area of about 50 square feet per lineal foot of viaduct. In rear of the left abutment of the main bridge, however, the ground has been disturbed by excavation from the chambers of the abutment curb drawing in the earth from outside as previously described, and to bridge over this disturbed area it became necessary to have recourse to a block foundation. This consisted of a rectangular block of brickwork, 60 feet square, with 25 excavating chambers, each 6 feet square at the top, through which the earth was removed by Bull's dredgers worked be steam winches ; the block was sunk to a depth of 10 feet below datum, or 20 feet below ground level. The block foundation was built at the level of 12 feet above datum, on a grating or curb of old rails with wedge timbers to serve as a cutting edge bolted to the underside ; on this rail grating and bolted to it 36 vertical rails were erected at suitable spaces, with horizontal connecting rails at intervals of 5 feet, the whole forming a substantia skeleton framing as a bond for the brickwork during the process of undersinking. The lower portion of the brickwork inside the chambers was taper to facilitate sinking through the silt, and the bottom length of 3 feet was built in cement. The total height of the 60-foot block is 20 feet When sunk to the depth of 10 feet below datum the excavating chambers were filled with concrete and brickwork, making it a solid mass weighing some 4,000 tons. After giving time for the setting of the brickwork and concrete and for settlement, the viaduct was completed over the block foundation and connected with the abutment. A crack has since occurred between the viaduct and the abutment, probably due to the fall of the water level in the river, reducing the upward pressure on the base of the 60-foot block.

(To be continued.)

Prof. Elihu Thomson has recently devised a method of case-hardening iron or steel by means of the heat produced by the passage of an electric current. His process consists essentially in heating the object electrically, and then applying to the metal so heated a surrounding envelope—either gaseous, fluid or solid—for the purpose of changing or preventing change in the quality of the material, according to the special end to be attained.

A sum of money sufficient to establish an annual prize of $120 has been donated by Mr. Charles Macdonald, of the Union Bridge Company, to the Rensselaer Polytechnic Institute. The prize will be given to the student who presents the best graduating thesis involving an original design of an engineering work, or an original investigation of a process which may be of special interest to civil engineers.

In the recent armor tests at Annapolis, Md., with Creusot solid steel and nickel steel plates, and Cammell compound plates, the solid steel plate was penetrated and cracked from circumference to center by a shot from an 8-inch rifle; the nickel plate was penetrated, but intact; the Cammel plate was completely wrecked.

A force of about 1,500 men is now employed by the construction company on the Nicaragua Canal.

LOUVRE FOR VENTILATOR FOR TRAIN-SHED ROOF TO LET OUT SMOKE AND EXCLUDE SNOW.

THE following letter from P. A. Petersen, Chief Engineer of the Canadian Pacific Railroad Company, refers to the articles in Volume XVIII, pp. 307 and 321, in which were published his original communication, and responses describing two structures, intended to meet the given conditions. One of the designs was by C. L. Stroble, C E., for train shed ventilators on the Chicago, Milwaukee and St. Paul Railroad, and the Chicago and Great Western Railroad, and the other was a detail of the louvre in the Metropolitan Opera House, New York.

THE CANADIAN PACIFIC RAILWAY CO.
MONTREAL, September 11, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: You will remember that on the 1st of November, 1888, I wrote you asking where I could find a drawing or description of a louvre that would act satisfactorily as a ventilator for a train shed roof, so arranged that it would carry out all the smoke and at the same time keep the snow from drifting in. I obtained, through your paper, descriptions and sketches from several correspondents. I did not think that any of them would be quite satisfactory in keeping out the fine drifting snow. I now inclose you a drawing of one that has answered every purpose. In summer, with the upper windows open, it ventilates the train shed thoroughly, and lets out all the smoke. In winter, with the windows closed, it keeps out all fine drifting snow and the smoke passes freely through the openings between the rafters, over the windows, and under the roof boards.

Trusting this may be of use to some of the correspondents who were kind enough to answer my letter, believe me. Yours very truly, P. A. PETERSON,
Chief Engineer.

We publish herewith full illustrations of the construction adopted by Mr. Petersen, and found satisfactory under the exacting conditions and wide climatic variations where it was used. Figure 1 is a general cross section of the train shed; Fig. 2 is an enlarged elevation of the louvre details at A A, Fig. 1; Fig. 3 is an elevation at Z Z, Figs. 1 and 4; and Fig. 4 is a section at X X, of Figs. 2 and 3.

EXPLOSIONS FROM UNKNOWN CAUSES.

As the first of several mysterious explosions, described in a paper presented this week at the New York meeting of the American Institute of Mining Engineers, Mr. James C. Bayles mentioned the bursting of a 16-inch pipe carrying air under a pressure of about one pound. The pipe was made of light galvanized iron with soldered seams. Into it a rotary fan-blower delivered air, and from it smaller pipes were carried to furnaces. The blower was run continuously. Neither the main pipe or its branches has any connection with the gas conduits. Both air and gas pipes delivered into the furnaces; but although the gas was under much higher compression than the air, there appeared to be no good reason why, having free escape in case of leakage, it should ever make its way back into the air-pipe. One warm afternoon in June the main air-pipe exploded with great violence. Every window in the mill was blown out, a considerable section of the roof was raised an inch or two, and in several places it was blown through. The pipe was torn into a thousand pieces.

The pipe in which the explosion occurred extended the whole length of the mill. The pipe welding machines to which the air was supplied were placed together near the end connected with a blower, leaving some 80 feet of what may be called dead end. It was in this dead end that the explosion occurred. The portion of the pipe from which outlets were taken were substantially uninjured, but 75 feet of the 80 feet beyond the furthest outlet were utterly destroyed. The fact that with very little mending the part of the pipe which the explosion had not reached continued for some months to supply the machines with air shows how local the explosion was, and the damage to the mill building gave sufficient evidence of its violence.

The natural explanation of this explosion is that gas found its way into the air-pipe and was packed away in the dead end, and that when mixed with air in explosive proportions it reached a furnace and exploded. The most rigid investigation failed to explain how the gas got into the air-pipe against the pressure it carried, and why an explosion beginning at a furnace should have restricted its effects to the dead end of the air-pipe. Mr. Bayles thought that it was, undoubtedly, a gas or vapor explosion and that the vapor was formed by the volatilization of the oil consumed in lubricating the trunnions of the blower. He thought it conceivable that the large amount of oil consumed by the blower is volatilized, and that it becomes a hydro-carbon gas which would behave like any other gas of similar composition. This gas, being lighter than air, would occupy the upper part of the pipe and remain undisturbed while air was drawn from outlets taken from its under side. This light gas may have worked along and accumulated in the dead end of the air-pipe until it reached, in admixture with air, the explosive condition. How it was fired, however, still remained unanswered.

The second of the curious accidents was the explosion of a No. 6 Sturtevant Blower. The blower was inside the mill, and was driven by two belts from pulleys on the main line of shafting. It was used to furnish blast for gas generators. Some trouble with the main driving belt necessitated a stoppage of the mill engine, and the blower stopped. In a few minutes the engine started again, and with it the blower. Suddenly it disappeared. Fragments weighing 20 to 50 pounds were distributed in all directions. The explosion was accompanied by a violent report, and succeeded by a dense cloud of yellow-brown, offensive-smelling smoke, which rose to the roof, rolled right and left, and finally escaped at the monitor.

The conclusion was that during the stoppage of the engine some gas from the producers had worked back through the pipe into the blower. When the blast was resumed these products of imperfect combustion were carried with the air current into the producers, and being mingled in explosive proportions, had been fired by contact with the incandescent fuel and exploded. This explanation was never quite satisfactory. An explosion which began in the producer could only reach the blower through two branches of a tee, 6 feet of vertical pipe, an elbow, 25 feet of horizontal pipe underground, another elbow, 6 or 8 feet of vertical pipe, another elbow, and 4 feet, more or less, of pipe connected with the outlet of the blower. Some of these pipes were light and some heavy, and the section underground was much larger than the section at either end of the run. If an explosion violent enough to wreck the blower completely had occurred through the whole length of this very circuitous pipe, there should have been some evidence of it in the pipe itself. It was intact. Not a joint was started. Furthermore, as the blower had been running at least four minutes immediately before the explosion, what could have remained in it to explode? The fact was, however, that the blower was shattered, while the pipe was undisturbed, even the delivery nozzle of the blower remaining coupled to the length of pipe on the mill floor, which was not thrown out of line.

STONE PIPES FOR WATER SUPPLY.

In an interesting paper on American and foreign practice with diamond drills, presented by Mr. W. F. Durfee, of Birdsboro, Pa., before the American Institute of Mining Engineers, at New York, on Monday evening last, it was pointed out that while Professor Rudolph Leschot, a French engineer, was the first in modern times, 1862, to perforate rocks by means of a hollow, cylindrical drill, armed with diamonds as cutting agents, and thus leaving a core of solid material in the center of the hole, he was not the first to suggest the idea of drilling a hole by means of a rotating, hollow tool.

As early as the beginning of the century James Murdoch, one of the principal assistants of James Watt, conceived the idea of making pipes of stone for conveying water. Mr. Murdoch's invention was carried into effect by means of a thin, hollow cylinder of soft iron, to which was given an alternate rotary motion, the lower end of the cylinder being copiously supplied with sand and water.

Such stone pipes were, in the early part of this century, an article of manufacture, and it is a matter of record that the pipes for the first water supply of Manchester, England, were made by this process. This fact appearing of curious interest in its relation to the history of the water supply of that city, Mr. Durfee took pains to procure some authoritative information in regard to it, and obtained from the Hon. James G. Blaine, Secretary of State, the following data, secured at his request, by the Hon. W. F. Grinnell, U. S. Consul at Manchester, from F. H. G. Berry, C. E., of the Manchester Corporation Water-Works.

Mr. Berry says that the old Manchester and Salford Water-Works Company, in whose hands the water-supply was, previous to 1857, laid down stone service pipes, in the years from 1810 to 1814, in the streets, for supplying water. These pipes were bored out of soft, oolitic limestone, procured from a quarry in the west of England, and were cut into about 2-foot lengths, with spigot and socket joints which were united with Roman cement. Their bore was from 3 to 18 inches. The prices paid for the pipes were:

3-inch bore	4s. 11d.	per yard.
4 "	7s. 8d.	"
6 "	11s. 6d.	"
7 "	13s. 9d.	"
8 "	16s 0d.	"
9 "	18s. 8d.	"
12 "	30s 9d.	"
15 "	35s. 0d.	"
18 "	45s. 0d.	"

On being charged with water, however, most of the pipes were found to be incapable of bearing the pressure, and their use, except in the higher parts of the district where the pressure was low, was abandoned in favor of cast-iron pipes. Some of the stone pipes taken out of the ground can still be seen. Pieces have also been placed in the public parks at Manchester.

According to London *Engineering*, Japan has now 10,402 miles of railroad in operation and 874 miles in course of construction.

COST OF ROAD-MAKING MACHINERY AND MAINTENANCE.

The Manchester, N. H., *Mirror and American* recently published a most sensible and timely article on the cost of maintaining good roads, with special reference to road-making machinery. In view of the general applicability of the remarks made we reprint the article in full:

"Many a community has been scared out of improving its roads by the bugbear of 'expensive machinery.' This is wholly a bugbear, for road-making machinery is not expensive. It is far less costly than are poor roads.

"It may be interesting to describe the outfit which would be required, give its cost and estimate the expense of running it.

"If a town decides that its roads should be macadamized the first requisite is crushed stone. The old method of breaking stone by hand is very expensive, and has been generally abandoned in these days of improved and cheap machinery, so a stone crusher is essential.

"On a country road the total width of which may be too great to cover entirely with broken stone, there should be at least a macadamized width running through its center of 15 or 18 feet, and this roadway should be made with not less a depth of consolidated and screened broken stone than 9 inches. A cubic yard of broken stone will in such case cover an area of about 3½ square yards; and the material named, with a small quantity of good clean sand or fine gravel for binding material, will be all that is necessary, except intelligent labor and intelligent supervision to complete the work. It is hardly necessary to say that neither the work nor the supervision can become intelligent or satisfactory without the aid of the proper machinery for carrying out the construction of the road.

"A stone crusher costing $1,200 with engine, will break 75 to 100 tons per day. The engine will consume about half a ton of coal daily, costing probably $2. Besides this an engineer will be required at a daily wage of about $2.50, and two laborers will be necessary to feed the crusher. Their wages will average $1.75 a day. This makes the daily cost of running the stone crusher, with other incidental expenses, about $10.

"It is impossible to estimate the cost of getting the unbroken stone to the crusher and the broken stone back to the road again, for that depends entirely upon the distance which has to be traversed in cartage and the condition of the ground over which the loads are hauled. This is a matter where a grain or two of common sense in the placing of the crusher, etc., will have a decided effect on the expense. If the loads have to be hauled a considerable distance to or from the crusher, or if heavy grades have to be climbed or rough ground traversed, the time occupied in hauling each load will be increased and less can be hauled in a day, thus lessening the work done by horses and drivers for each day's wages. It is sometimes even an economical thing to devote the first stone and the first labor to preparing a smooth roadway between the quarry and crusher and the road to be improved. In this way time in hauling the loads is saved, and if the surface over which they are drawn is smooth the pulling power of each horse is largely increased.

"Where stone is to be obtained in more than one place along the line of the projected road, it is sometimes more economical to take the crusher to the stone than to have to haul the broken stone a great distance. For this purpose a stone crusher can be mounted on wheels and the steam roller (mentioned hereafter) be used to haul and drive the crusher without the expense of a fixed plant for crushing stone.

"In addition to the crusher a heavy steam road roller is more or less necessary. Of course the work can be done if necessary by horse rollers, but the results are never so good, and the difference in endurance of a road prepared by a heavy steam roller over one prepared with the comparatively light rollers drawn by horse-power is inevitably enough to pay the first cost and expense of running the steam roller over and over again.

"The first cost of a steam roller weighing from 10 to 15 tons will be from $3,500 to $4,500. To manipulate this roller only one man will be required, and his pay is not likely to be more than $2.50 per day. Placing the cost of fuel at $1.50 per day (a large estimate), the roller costs the community only $4 per day of operation. One of these rollers of good make can easily consolidate 1,000 square yards in a day at a cost of less than one cent per yard. Aside from this the roller can be put to other uses, if handled by intelligent men. When not in use as a roller its engine can furnish power for the crusher, it can, as has been said, haul the stone, or, as was done in an English town, 'pull stumps and drag heavily loaded wagons over unfinished portions of the roadway.'

"The only machines, aside from the steam roller and stone crusher, which can be spoken of as absolutely necessary, are rock drills to be used in the preparatory duty of blasting the stone, and these are generally to be found in every neighborhood where any quarry work is done. In case it is necessary to buy them they will cost $300 or less each. One man at $2.50 a day will operate them, and the steam supply will cost but little.

"If one estimates the cost of improving the roads of a district at $100,000, exclusive of machinery, it is not fair to add more than 10 per cent. to that sum as the sum to be expended on crusher, roller and drills, and this may be materially decreased by co operation. One crusher and one roller are quite capable of doing the work of several communities if each takes its turn, and thus, providing each district pays its share of the original expense, or if one district buys the machines and rents them to the others at reasonable rates when not at work on its own roads, the expense of the machinery becomes really a very minor affair."

EXCAVATION OF THE CROTON AQUEDUCT, NEW YORK.

In a paper on the above subject presented this week before the American Institute of Mining Engineers, Mr. J. P. Carson gave a series of interesting notes relating to the mining part of the great work. Mr. Carson's description of the tunneling through the bad ground found near Shaft 13 is in substance as follows:

On June 1, 1885, the tunnel at the foot of the shaft was commenced, and advanced at the rate of 80 feet a month for 392 feet through hard dolomitic limestone, which then became softer. Fifteen feet further, at station 777 + 59, on the east side of the heading, a fissure was cut on December 9, and the trouble began. There poured out a mixture of decomposed limestone, clay, sand and dirty water, which soon partially filled the tunnel for 125 feet, and amounted to about 100 cubic yards. After three days the water became clear, the fissure was plugged with straw, and the heading advanced 20 feet further. Then, on December 22, without warning, another outpour three times greater than the first occurred. The men were driven out, and everything in the heading for 50 feet was covered out of sight.

Timbering so as to allow for 20-inch brickwork was then commenced at the soft rock. At the end of two months the heading had been cautiously advanced 34 feet to 778 + 13, and 17 sets of timber placed, the last two being reinforced with heavy hemlock spreaders. A bulkhead was then built at the end of the timbers, at 778 + 09, this being the edge of the soft ground on the east side. The bench during this time had been brought up, and was 32 feet behind at 777 + 77.

For several days the clay and mud in the face of the heading were continually forced inwards. Some idea of the pressure may be formed from the fact that 24-inch oak logs used as rakers at the bulkheads became so crushed after 24 hours that they had to be continuously renewed. A small cave on the surface then occurred; finally, on February 20, this was followed by a much larger one, about 25 feet east of the center line. It was directly in the line of a small stream, which partly filled it with water. The stream was immediately diverted and a pump rigged to remove the water from the hole. This cave was supposed to be the mouth of the original fissure, and an abortive attempt was made to clog it up by throwing in bales of hay, cedar-brush, logs and stumps. Either from the fact that the course of the brook had not been properly diverted, or by reason of the sudden thaw or local conditions, this debris gently glided down into the tunnel, completely filling it for 70 feet, and gradually sloping down to a depth of 1.5 feet for 312 feet, or to within 75 feet of the foot of the shaft. It amounted to about 1,189 cubic yards.

Faith in the theory of a fissure in the limestone led to the plan of a crib. It was aimed to strike the fissure, which was to be arched over, or otherwise closed. The dimensions were 12x12 feet on the outside. It was sunk to a depth of 50 feet, when, hardpan occurring on the west side, it began to sink irregularly. After three weeks' work and the expenditure of about $900, the contractors concluded that they had expended the amount allowed "for any work they should do on the surface, to be paid after the tunnel was through," and stopped.

At this time several plans were proposed. Among the most feasible were the following: Charles M. Kalmbach, a well-known tunnel expert, proposed to drive a heading below sub-grade and fill with concrete; to then gradually widen out and thus obtain a foundation. The division engineer in charge, Alfred Craven, proposed instead, a timber platform of oak or Georgia pine, upon which the concrete should be laid, and to change the section from the horseshoe to the circle. This was generally conceded to be right, but in the following August it was decided to use white oak for the platform and return to the horseshoe section; and this plan was formally approved January 10, 1887, but not fully adopted by the contractors until the year after. In the next year the work was carried on with a series of experimental drifts, conforming to no regular system of timbering, and the means adopted were entirely inadequate to the work in hand.

In March there occurred an entire change in the management. The English system was introduced, and the work, without serious interruption, was completed in a year and two months.

Mr. Carson further gave some miscellaneous information as follows:

The amount of brickwork laid in the New Croton Aqueduct is estimated at 312,258 cubic yards, or about 163,000,000 of bricks, which would build 33 structures the size of the *Tribune* building.

The total area of the inside surface of the aqueduct from Croton Lake to One Hundred and Thirty-fifth Street gate-house is equal to 7,092,823 square feet, or 162,83 acres, or about equal to one-fifth the area of Central Park.

The total excavated material of the entire aqueduct exceeds 2,800,000 cubic yards.

The total excavated material plus the masonry placed exceeds 3,250,000 cubic yards. This is equivalent to 83 per cent. of the volume of the great pyramid of Cheops.

This material would be sufficient to build a wall 10 feet thick and 55 feet high around Manhattan Island, 30 miles in length on the water front.

The amount of dynamite used in blasting on the aqueduct, exclusive of the amount used in sinking the shafts, was over 5,800,000 pounds, or over 2,900 tons.

The flowing capacity of the aqueduct, 318,000,000 gallons per 24 hours, is equivalent to a stream 50 feet wide and 10 feet deep flowing 59.1 feet per minute, or about one foot per second, or about seven-tenths of a mile per hour.

DIAMOND DRILL PRACTICE.

IN reviewing American and foreign practice with the diamond drill in a paper read before the American Institute of Mining Engineers at New York last Monday, Mr. W. F. Durfee stated that the art of penetrating the earth's crust by drills of various kinds is a very ancient one, and has been practiced in Asia from the earliest times.

A French missionary, the Abbé Imbert, relates that, when in China, he "had seen many bored wells, of a diameter of five or six inches, and a depth of 1,500 to 1,800 feet," and his description of the method followed would answer for that in use at the present day for boring wells with percussion tools, by merely substituting steam for manual power, the apparatus used for boring being nearly identical. In fact, it is to the ingenuity of the Chinese that we owe the system of boring wells by the use of a steel implement suspended at the end of, and operated by, a rope, as distinguished from the more modern method, in which the operating tool is secured to the lower end of a series of screw-jointed rods by which a turning and percussive movement is communicated to it.

The method of action of the present form of diamond drill involves no percussive shocks whatever, but operates by a movement of continuous rotation and progression, the rock being abraded by the action of a number of black diamonds firmly imbedded in the end as well as the inner and outer circumference of a short hollow cylinder, called a "bit." This is attached to the lower end of an externally grooved tube, called a "core barrel," which, in turn, is attached to a succession of hollow rods properly coupled together, end to end, until they reach the boring machine, where they pass through and are secured to a hollow spindle to which rapid rotary motion can be given by power. To the upper end of these hollow rods is attached an apparatus called a "water swivel," to which is connected a "water hose," the swivel being so contrived that the hollow drill rod can turn without winding up the hose. Through the latter is constantly forced a stream of cold water under sufficient pressure to maintain a continuous current downward through the hollow revolving drill rods and core barrel, and upwards between the outside of these and the inside of the hole to the surface of the ground, or to some fissure in the rock through which the water can escape. The rapid flow of this water not only carries off the fine particles of rock removed by the bit, but serves, at the same time, to keep the latter cool.

It will be understood that the diamond drill does not remove the whole of the rock by its abrasive rotation, but that a central portion, or core, is left, which can be removed from the hole in a solid form in lengths of from 8 to 10 feet. It is further manifest that a succession of such "cores," arranged in the order of their extraction will give an exact record of the character and order of the strata through which the hole is being driven.

The active and indispensable part of this core-making apparatus is the already mentioned diamond-mounted bit. The bits are, in fact, diamond-toothed rasps, the teeth being formed of black diamonds, or carbonadoes, as they are more properly called. These were first discovered in the diamond gravels of Brazil, in 1842, and it is from that country that the world still derives its supply. The metal of the bit is soft steel, in which holes of various sizes, suited to the sizes of the diamonds, are formed. Each diamond being placed in its cavity, the surrounding metal is closed against it and made to overlap it in some degree by means of punches. Some of the diamonds project on the outside and others on the inside of the bit, and are for the purpose of cutting an external and internal clearance, so that the core produced will not fill the core barrel completely, and that the latter will have freedom of movement in the hole. The bit is provided with a screw by which it is attached to the "core lifter" case. The latter, with the little apparatus within it called the "core lifter," performs an important office in the work of the drill, as it passes freely over the core while the drill is revolving and penetrating the rock, but grasps it firmly whenever the drill is lifted. Whenever the core barrel is filled with the core, it is raised from the hole, the core lifter meanwhile holding the core. The lifter consists of two parts, the core lifter ring and its enveloping case. These are combined and operated together.

The speed, or rather the number of feet per day that can be bored in a given hole, depends upon the hardness of the rock and the depth at which the boring is being done; for while the actual boring can be done at the same rate when the hole is deep as when it is shallow, the time lost in drawing the rods in a deep hole is so great as to seriously influence the depth of drilling in a given time. It is, therefore, difficult to name a figure that will represent the average rate of boring. One hundred feet per week of cored 2-inch hole is probably not far from an average speed. Holes have been drilled at the rate of one foot per minute in sandstone, but the durations of the run was short, and this speed could not be maintained continuously for any great length of time. Holes have been driven in anthracite coal at the rate of 22 inches per minute. The fastest drilling in regular work, within Mr. Durfee's knowledge, was done in sinking a shaft for the Westmoreland Coal Company, in which a 1¾-inch hole was driven, with a solid bit, 171 feet in 10 hours. As the speed is irregular and uncertain, so is the cost. Mr. L. A. Riley, in a previous paper to the American Institute of Mining Engineers, gives as the average cost of drilling 24 holes for the Lehigh Valley Coal Company, $2.22 per foot, to which he adds 20 cents per foot for royalty, interest, and wear and tear, making a total of $2.42 per foot. His greatest cost is $4.08 per foot, and the cheapest, $1.18. These figures are without margin of profit to any one. Under ordinary conditions contracts are taken, for 2-inch holes, at from $2.50 to $4 00 per foot, the price depending, in no small measure, upon the quantity of work at a given location.

THE FRESH-WATER WELLS OF THE ATLANTIC BEACH.

DR. PERSIFOR FRAZER, writing in the September number of the *Journal* of the Franklin Institute, says that anything which will throw light upon the character of the drinking water which is supplied to the hundreds of thousands of sojourners by the New Jersey sea coast, must necessarily have interest to the public.

The practice, during the last five years, has tended toward sinking artesian wells near most of the larger summer hotels. The supply of water by this means was so abundant and excellent that the New Jersey State Geological Survey, under the late Professor George Cook, determined the water-bearing planes, and published the depths at which these might be expected in bore holes along the sea coast from Sandy Hook to Cape May. The wells which have since been driven have amply proved the soundness of the data.

But in numbers of cases it is not possible to resort to deep boring, and in these cases the supply is by surface wells sunk a short distance below the sand. Of course, these wells are permissible only in cases where, for a considerable distance around them, the population is sparse and there are few cesspools or collections of decaying matter, and in some cases these conditions obtain sufficiently to justify the use of surface wells, but sooner or later these must be abandoned and recourse must he had to artesian borings, which, fortunately, need not be very deep, to furnish an ample supply for all needs.

In order to give to the layman an idea of the condition of the strata and their relation to the water supply of the coast, it may be said that the famous marl beds of New Jersey, with the clays and sands which divide and intermingle with them, form impervious beds through which water cannot percolate. They cross the State from about Long Branch to the old town of Salem, near Fort Delaware, running approximately southwest, and inclining or dipping in a direction perpendicular to this (or southeast), at a gentle angle of about 20 feet to the mile. These are the water-bearing floors which supply the greater part of the artesian wells sunk along the coast between Long Branch and Cape May, though there are other and higher planes along which more or less good water is constantly flowing downward to and entering the sea at a greater or less distance from the coast. The permanence and purity of a supply will depend upon the extent of country which pours its rainfall upon the upper edges of these marl strata or the overlying clay beds. The outcrop of these strata is not parallel with the coast line, but runs inland to the southwest; it is, therefore, obvious that the farther one goes to the south from the intersection of these strata with the ocean border, the deeper must the well be bored in order to find water. One of the upper marl beds touches the sea line at Asbury Park, and the next higher marl at about Branchport. To reach the water flowing along the upper planes of the first deposit at the Beach House, Sea Girt, for instance, one would be obliged to sink about 160 feet; and to reach the probably larger supply of the marl next below at the same point, a depth of 240 feet would be required. But before coming upon these well-known horizons of good water, it is extremely probable that others would be found, representing higher clays, as was the case at Berkeley, on the Barnegat Beach.

But to return to the surface wells. There is at the Beach House a well sunk by Commodore Stockton, when the middle house was his seaside home. This well is a prominent object on the lower porch of the hotel, and furnishes all the water consumed for drinking and cooking purposes. The depth of the bottom of the well is 20 feet 5 inches from the surface, and its average depth of water is 3 feet. One of its peculiarities, which astonishes those unfamiliar with the behavior of streams of water at points near their confluence with another body of water of varying depth, is that the level of the perfectly sweet and fresh water rises and falls with the tide in the ocean 150 feet to the east of it. This is not at all remarkable when one reflects that the same ocean tide causes the fresh water of the Delaware and Schuylkill to rise, and their surface currents to retreat towards the mouths of those streams, though eighty-odd miles from the ocean.

The water which fills this well represents the drainage of a few square miles around Sea Girt, and is simply the rain water filtered through the sand and gravel of the coast belt, and collected on the surface of some local intercalated bed of clay. Were the region thus drained as thickly populated as a few other parts of the coastal belt the water would probably be unfit for drinking purposes; but it happens that the settlement of this area is sparse and its contamination from putrifying substances small.

For the purpose of investigating whether or not it were potable as well as to learn something of the nature of the water from similar wells on the New Jersey coast, having first filled and rinsed a perfectly clean five-gallon demijohn 12 times with water, Dr. Frazer collected a fair average sample. Subjoined are the results of this examination.

Water slightly alkaline.	In a Million Parts.	Grains per Gallon.
Free ammonia	0.033	.....
Albuminoid ammonia	0.030	.
Chlorine	...	4.2
Total solids in solution	.....	29.0

As to the two forms of ammonia this corresponds closely with an analysis by Wanklyn, of the water of the river Lea, supplied by the East London Water Company to the citizens of London. The percentage of albuminoid ammonia is only 0.01 higher than that found by the same distinguished analyst in the water of Loch Katrine, which supplies the people of Glasgow. While not extraordinary on account of its purity it is well within the limits beyond which chemical analysis indicates danger.

The same is the case with the chlorine and total solid constituents. They present no ground for suspicion of dangerous contamination, and indicate what a subsequent examination of the drainage system proved, viz: That the latter was in good condition, and carried all sewage in closed pipes to an inlet connecting with the Manasquan River about a mile away from the house. This is but one instance, and it may be an exceptional one, on the coast of New Jersey, where a surface well is still utilizable. The time will come when such supply can no longer be resorted to, but in this case it has not yet arrived.

ACCORDING to *Kuhlow's German Trade Review*, the entries which have already been made for the electrical exhibition to be held at Frankfort-on-the-Main, Germany, appear to promise an exceptionally fine showing.

VICTORIA, B. C., by popular vote, has decided to have sewers. The Victoria *Daily Colonist* emphasizes the desirability of losing no time in beginning the work of construction.

THE PANAMA CANAL.

THE report, just published, of the Engineering Commission sent to the Isthmus of Panama by the Liquidator of the Panama Canal Company is not of a nature to give much hope for the enterprise. Primarily it sets forth that the problem should be resolved by the study of two questions: first, what will it cost to finish the canal? second, what will be the income of the canal when finished? that is, immediately after its opening or after a given time.

"Before discussing the two questions," says the report, "it will be necessary to consider the spot on which this great work is to be done. In short, it is a place resembling nothing with which we are familiar as the scene of a great work. It cannot be compared with any great undertaking of our times, and to judge of it by European experience and work will be to lay ourselves open to the most serious misconstruction. Under the hot, humid, enervating climate of the isthmus, surrounded by the emanations of a rich, clayey soil, amid swamps, in a country but sparsely populated, covered by a dense tropical vegetation that nothing can check, the white race cannot undertake steady work of a laborious character without returning from time to time to a healthier climate to reinvigorate themselves. Under such conditions they can exist, handle machinery, and work under cover away from the sun and rain. But to dig into the earth and do steady manual labor in the open as men do in our climate is impossible, unless they expect the early failure of their health and strength."

Dr. Wolfred Nelson, who has spent a number of years at Panama, says that the year on the isthmus is divided into two seasons—the dry season or Verano, from the middle of December to the middle of May, and the wet season, lasting the remaining seven months. The annual rainfall is 3 meters—over 118 inches. The effect of these enormous downpours on a clay soil is to turn the rivers into raging torrents. On this subject the engineers say:

"The most important of the rivers is the Chagres, in whose valley fully one-half the canal must be constructed. The river in the wet season rises from 10 to 12 meters in 36 hours. At its maximum it discharges 1,500 cubic meters a second, and may double that. On this score we are reduced to conjecture, and cannot say what difficulties will have to be overcome in combatting this torrent.

"Next, as an obstacle between the two oceans is the Cordillera, which must be divided to open a way for passage of vessels. The height of the mountain above the sea is about 339 feet, and whatever solution may be adopted, a cut of over four miles long must be made. This work will require great time." Next the geological formation is treated, its peculiarities, and the impossibility of making sharp-angled sides to the huge cut. Again, the report of the engineers dwells on the fact that no European standards of work can be applied to isthmian work. Then it deals with earthquakes and reports as follows:

"To these inherent difficulties must be added a danger peculiar to the country, namely, earthquakes, the importance of which has been denied by some and exaggerated by others." Regarding the great cut to be made in the Culebra it says: "During an earthquake what effect might result on the sides of a cut 100 to 150 meters in height? Would it not shake from the hills great masses of rock, damaging the walls or sides of the cutting, in short, disturbing their stability? Here an inevitable uncertainty develops, regarding which the Commission expresses no opinion."

While the physical difficulties that must be overcome are severe, Dr. Nelson is inclined to think that far more important questions are those of time and expense. These matters he has made subjects of considerable investigation. The concession lapses in 1892, but an extension of six years may be granted by the President of the United States of Columbia. Even though this is done, Dr. Nelson does not deem the six years sufficient to complete so huge a work.

The highly important question of supposed revenue—which is a matter of extreme uncertainty -has been figured on by French scientists ever since the project was begun. In the light of recent developments Dr. Nelson says that for the first four years a revenue of 51,250,000 francs is expected. This is calculated at 12 francs a ton, which, less working expenses and dues to the Government of Columbia, leaves a net revenue of 38,678,500 francs. Four years later it should be 63,750,000 francs, on a traffic of 5,100,000 tons at 12 francs, which, less maintenance, etc., leaves 13,187,500 francs a net revenue of 50,562,500 francs. Again, four years later, on a tonnage of 6,000,000 the gross revenue should be 75,000,000 francs, which, less a maintenance of 13,750,000 francs, leaves a net revenue of 61,250,000 francs.

As to the question of cost, he estimates that 899,000,000 francs, including interest, will have to be expended to complete the ditch, that is, if the old share and bond holders are willing to come to an agreement by which they forego all interest for many years to come and trust to a future development of traffic. The working expenses and maintenance of the plant, he estimates, will reach 2,000,000 francs ($400,000) per annum.

Despite the desire to see a clear horizon, Dr. Nelson says that French engineering experts cannot dissipate the doubt that the canal's future is less assured than that of the Suez Canal; that the expense at Panama and the annual charges will be heavier, the tariff higher, and the facilities for shipping less.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

LARGE SIZE VITRIFIED PIPE FOR SEWERS.

PROVIDENCE, R. I., September 26, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

SIR: I read with interest, mingled with some surprise, the quotation from an address delivered at Columbus on the subject of sewerage, as published in THE ENGINEERING AND BUILDING RECORD of September 13.

It would have been interesting if the author of the address had given us the data of his experience, which led him to state so emphatically that the material of which 18, 20, and 24-inch vitrified pipe is made is not a safe one to use in these large diameters. That pipes 24 inches, or 20 inches, or 18 inches in diameter have failed, there is no doubt, nor is there any doubt that failures have occurred in the use of 15-inch, or 15-inch, or 8-inch, or even in 6-inch pipe. It would, therefore, have been interesting to know the data which the author had in drawing the line of safety at 15 inches in the use of vitrified pipe for sewer work. My own opinion is that pipes as large as 24 inches in diameter are made, which, if properly laid, are safe and reliable.

In regard to the thickness of brick sewers, as you have stated, much depends upon the nature of the material in which the work is laid. Doubtless sewers three feet in diameter may often be built of a single course of brick, and give good results, in which case it is probable that good materials would be selected, and care taken in the construction of the work; but why it should follow that if any "engineer, contractor or inspector" be allowed to use two rings, "he may put in anything he likes," I do not understand. Why cannot the same good material be used, and the same care be exercised in the construction of work of two rings, as in one-ring work? Carrying the principle laid down by the author a little further, as for instance in the use of 12 or 16-inch work, would the material deteriorate in proportion? If not, why not?

SAMUEL M. GRAY, City Engineer.

PHILADELPHIA'S WATER CONSUMPTION.

IN ten years the daily consumption of water at Philadelphia has risen from 57,707,082 to 116,490,191 gallons, and it is thought that the daily average for 1890 will be 125,000,000 gallons.

This great increase in consumption is explained by the growth of the city and the fact that the more water that is given the people the more they want. It is estimated that only 10 per cent. of the water consumed is used for drinking and culinary purposes. Three years ago the storage capacity of all the reservoirs was 195,000,000 gallons; now it is 900,000,000 gallons, owing to the completion of the East Park Reservoir. Plans are now under consideration for two more reservoirs, which will add 600,000,000 gallons to the city's storage capacity.

HIGHWAY ENGINEERING.

THE Executive Committee of the Massachusetts Institute of Technology has accepted an offer of Colonel Albert A. Pope, of Boston, Mass., to contribute such sums of money as the institute may need during the next five years, up to the amount of $6,000, for the promotion of an option in highway engineering connected with the course in civil or mechanical engineering. This sum is to be used by the institute in preparing some competent graduate, by studies at home and abroad, for a nominal instructorship on this subject in the institute, and who will gather material and facts on the subject for the benefit of the institute, will deliver a course of lectures thereon yearly, and will be open to consultation by the officials of towns and cities not employing permanent city engineers. It is expected that the option will eventually lead to the establishment of a department on highway engineering.

CHINA has 136 telegraph stations. The system is mainly controlled by the government.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department.* Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

LOWERING A WATER MAIN.

W. L. CAMERON, Superintendent of the Artesian Water Company, at Memphis, Tenn., writes:

"In your issue of September 13, I notice a very elaborate plan for the lowering of a 10-inch pipe. With no desire to criticise, still I would suggest a more simple, and, I think, less expensive method.

"We lowered some 1,000 feet of 12-inch pipe, from 2½ to 4 feet, which was successfully accomplished by simply digging the trench to the necessary depth under the pipe, and a little wider on *one side* to prevent *jam* of *joints*, leaving under each bell (behind the bell) a support of earth 1 foot wide. When all was clear, we simply cut the bank an inch or so at a time and allowed the pipe to settle. One or more calkers were on hand to keep joints calked up.

"All fire hydrant branches were handled in the same way, and the pipe was lowered without the pressure (some 50 or 60 pounds) being taken off. No blocking or rods were used. In a rock trench, jacks can be placed under every second or third joint, and the pipe lowered by simply moving blocking, as same goes down.

"In this manner we lowered some 300 feet of 24 inch suction pipe, through which a 6,000,000 pump was deriving its supply, and the engine never felt any air leaks during the progress of the work."

HOW TO KILL GRASS AND WEEDS IN GUTTERS AND SIDEWALKS.

HENRY M. NOURSE, architect, of Boston, Mass., writes: "Replying to the query in your issue of September 20, 'How to Kill Grass and Weeds in Gutters and Sidewalks,' I would say that turpentine, used clear or very slightly diluted, applied with a fine-spray watering-pot, will take the nonsense out of the proudest weed that grows.

"A client of mine is taking the above measures to rid his lawn of weeds and bunch-grass; and as for its death-dealing qualities, he has not the slightest doubt, as it takes root and all.

"Rock salt, or a strong brine or pickle, I have known to give like results."

W. T. CASGRAIN, C. E., Superintendent of the Kimbell & Cobb Stone Company, of Chicago, Ill., writing with reference to the same subject, says: "Use common salt if grass and weeds are very plenty, and sprinkle with water until salt is dissolved. Where the joints in material used are close make a solution of salt (or brine strong enough to float a potato) and sprinkle over joints two or three times. This I found the easiest and quickest remedy for killing grass and weeds in gutters and walks of public parks."

STILL another correspondent recommends covering the gutter or sidewalk with about half an inch of dry sand on a hot day. This will burn the grass, and one hot day will generally kill it. The sand can then be scraped or swept off. This should be applied before the grass attains any great strength. If it has attained much growth the sand should be thicker, and would have to remain on longer.

MAKERS OF WROUGHT-IRON CEMENT-LINED PIPE.

JOS. S. KERN, JR., General Manager of the American Pipe Manufacturing Company, of Philadelphia, Pa., writes: "Noticing the inquiry about wrought-iron cement-lined pipe manufacturing companies in your issue of September 20, I beg leave to inform you that the New Haven Patent Water Pipe Company are not the only makers.

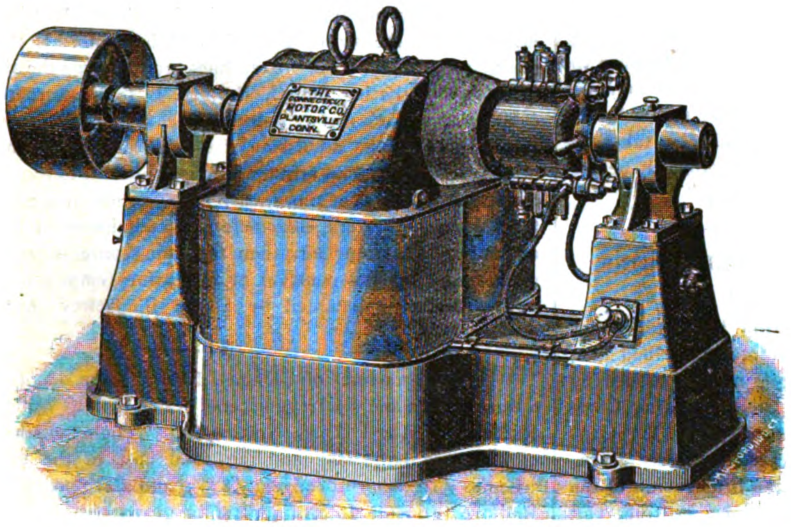
"We have manufactured under the Phipps patent for the past four years. The New York Pipe Manufacturing Company, with office in New York *Times* Building, and works at Hastings-on-the-Hudson, also makes it."

DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

ELECTRIC MOTORS.

THE electric motor business, which was in a nascent state a few years ago, has, of late, been developed at a remarkably rapid rate, and a large number of motors are now in use, and are constantly being added to, for a wide variety of power purposes.

In a general way, it may be said that they are employed in all those industries and lines of work formerly supplied by a small amount of steam power or by gas engines and water motors, which have been quite extensively employed during the last few years. Electric motors are now used for driving air compressors, bookbinding machinery, bakers' machinery, blowers, cranes, carpenters' machinery, cash carriers, coffee mills, churns, drug mills, dumb waiters, dentists' lathes, drill presses, elevators, grindstones, hydraulic presses, hatters' machinery, ice-cream freezers, jewelers' lathes, knitting machines, lathes, laundry machinery, looms, paper-box machinery, polishing machines, pile driving, printing presses, quotation transmitters, sewing machines, stamping machines, ventilating fans, and a hundred other small uses.



THE CONNECTICUT MOTOR CO. PLANTSVILLE CONN.

FIG. 1.—MOTOR OF THREE H. P.

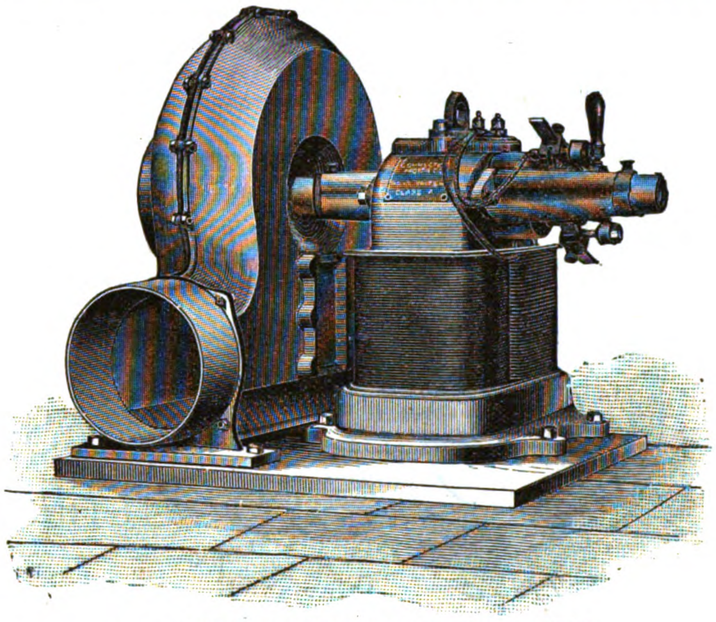


FIG. 3.—ONE H. P. MOTOR COUPLED TO BLOWER.

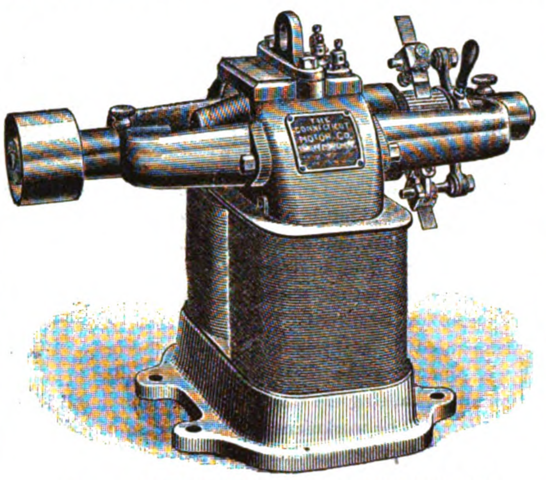
THE CONNECTICUT MOTOR, MADE BY THE CONNECTICUT MOTOR COMPANY, PLANTSVILLE, CONN.

Nothing more surely indicates the confidence now placed in the electric motor than the extent of its use by elevator men. In the case of belt driven elevators it is much used in localities where current is obtainable. With hydraulic elevators, worked from tanks, the motor is used to actuate the force pumps, which it does automatically without working to waste. Combinations in which the motor is geared direct to the elevator are now claiming the attention of the engineer in locations where space is of primary importance, though as yet this method has not found so much favor as those above mentioned. Under this heading comes a host of similar appliances, such as hoisting and winding engines for mines, and building work; cranes and gins for factories and warehouses. Printers have from the first appreciated the advantages of the electric motor. Newspaper men commonly require their power at night, and not by day. Job printers often use power for but a small proportion of their working hours, and, generally speaking, the printers who can make an economic use of steam plants are far outnumbered by those who cannot—with the result that the electric motor is now indirectly responsible for a large proportion of the reading matter placed before the public.

From among the lighter industries we select the application of sewing machines as one most frequently met with. Sewing machines usually require about one-twelfth horse-power each. This figure will be found high where many machines are run from the same shaft, and low if their number be small. The class of work done makes but little difference to the power absorbed, on account of the speeds varying almost inversely to the heaviness of the material sewed.

Wherever a moderate amount of power is needed the electric motor can supply it. The economy of the electric motor over small steam and gas engines is, moreover, claimed to be considerable, being based on the fact that the electric current is generated mainly in central stations by large engines, which consume much less coal for the power furnished than do an equivalent number of small engine and boiler plants. As to the cost of the electric current, it has been pointed out that electric light companies can afford to sell the power cheap, as the motor business is of great and positive advantage to them in giving employment and earning capacity to their plant when it would otherwise be idle and profitless. This will be understood when it is considered that most of the electric lighting is done at night, and the machinery and plant of the company is then employed, while during the day time it would be idle. As to the cost of the motors, it may be said that prices are constantly tending to become more reasonable, owing both to increasing competition and more rapid progress towards greater perfection in manufacturing facilities. Taking into consideration, further, that electric motors appeal at once to prospective users because of their greater neatness, cleanliness, and compactness, as compared with most other forms of engines, and that they require practically no attendance except for starting and stopping, their more general introduction would seem to be inevitable. As it is, their value is already widely appreciated, and those desiring to use them have a number of patterns from which to make selections.



THE CONNECTICUT MOTOR CO.

FIG. 2.—MOTOR OF TWO H. P. AND UNDER.

In view of all this an examination of what is now available in the electric motor line cannot fail to be of interest to many of our readers, principally, perhaps, architects and contractors having in hand the equipment of buildings with ventilating and water pumping machinery, etc.

We commence, therefore, in this issue the publication of brief illustrated descriptions of the various electric motors now on the market, having endeavored to make the list of manufacturers as complete as possible. The principal features of the motors are pointed out, the sizes in which they are made are given where they have been available, and some of their special applications are shown. The matter is not presented on the score of novelty since a number of the motors to be described have been for sale and in use for several years. It will, no doubt, be appreciated, however, as of practical value, by many who are confronted in every-day work with the problem of installing power plants to the best advantage for special service.

THE CONNECTICUT MOTOR.

The Connecticut electric motor, of which two forms are shown in Figs. 1 and 2, is made by the Connecticut Motor Company, of Plantsville, Conn.

The simple horseshoe magnet has been adopted in this, the poles being turned upwards, in order, it is claimed, to avoid the leakage which might otherwise occur through the bed plate, while, at the same time, the breech or neutral portion of the magnet becomes a solid base on which the machine rests. There are no magnetic joints, the whole field being in one casting of soft iron. The armature proportions are medium, the length being equal to about two diameters. The journals of the shafts are in all cases arranged to be self-oiling. In the type of machine shown in Fig. 1, designed for three horse-power and upwards, the shafts are fitted with oil wells, and in the smaller motors, of two horse-power and less, Figure 2, the bushings are lined with graphite. The holders for the brushes, which collect the current from the machine for further transmission, are of a new and improved pattern, having a light and fine spring adjustment. In Fig. 3, a one horse-power Connecticut motor is shown, coupled direct to a No. 2 Sturtevant exhaust fan. Fans, working usually at high speeds, are well adopted for such direct coupling, and, where not more than one fan is driven by a single motor, this arrangement is often used. It has proved to be of great value in cramped situations, such as are always found on shipboard, and usually provided by architects on shore.

The Connecticut Motor Company, some time ago, furnished the Pratt & Whitney Company, machine tool builders, of Hartford, Conn., with a motor for driving a large planer, to be run overtime. The planer required about three horse-power to operate it. The question came up as to the advisability of placing a motor in position to operate that planer, or to operate the regular engine and consume at least 10 or 15 horse-power uselessly in turning the shafting transmitting the power from the engine room to the planer. The motor was finally installed and answered every purpose most satisfactorily. This is but one instance out of many where the electric motor could be used with good results, and yet its employment in the machine shop is so rare as to always excite comment wherever and whenever it is found.

The motors are wound for potentials of 110, 220, and 500 volts, and should be placed in dry situations, well insulated from the earth. A safety fuse should be placed in the circuit, so as to prevent damage to the motor in case the current should exceed the normal working value. Twelve sizes of this motor are made, varying from ½ to 50 H. P.

(TO BE CONTINUED.)

ECCENTRIC STEAM FITTINGS.

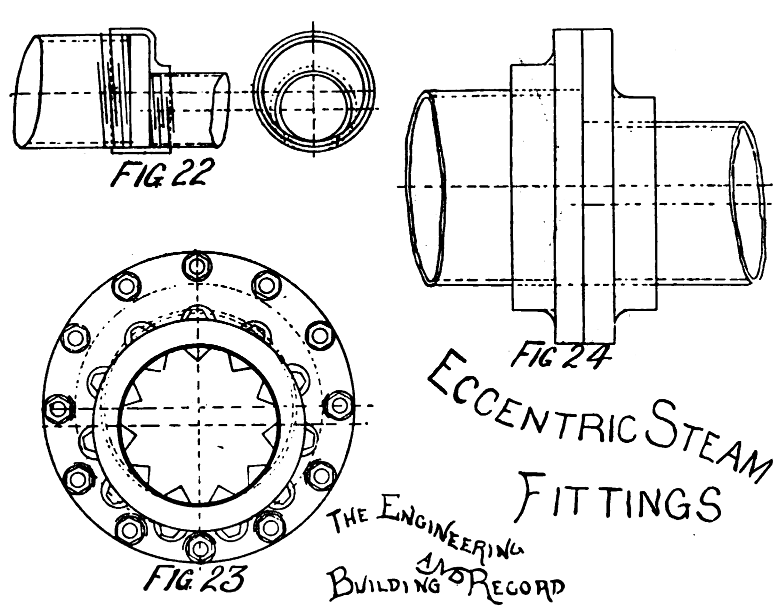
CONTINUING its articles on steam pipes and fittings, *The Locomotive* says that the application of the eccentric principle to main steam pipe connections can be extended with advantages to couplings for long lines of pipe and with especial advantage to fittings used in steam heating systems.

With the ordinary style of couplings, when the size of a steam main is reduced, it is necessary to put in a relief or drip pipe, sometimes at considerable expense and trouble, whereas if an eccentric reducing coupling were used, which would cost no more than one of the ordinary kind, the water of condensation would flow freely onward.

Figure 22 shows, in section, a form of reducing coupling which could be used with advantage on all sizes of pipe up to eight or ten inches in diameter. Figures 23 and 24, end and side views, of flange couplings for the larger sizes of pipe. The construction will be readily understood from an inspection of the cuts. The offset is just sufficient to bring the under sides of the pipes on the same level.

It will probably be urged as an objection to this style of fitting that they are not made and kept in stock by manufacturers of pipe fittings. This objection will vanish as soon as there is any demand for them. They will be found of far more use, and would probably be used a hundred times at least where a cross-valve is used once; still the latter is a standard fitting because it is occasionally called for.

While we have illustrated and described such eccentric fittings in earlier issues, their importance warrants recurrence to the subject.



Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

STEAM HEATING DATA.

"C. P. W. F.," Minneapolis, Minn., writes: "Will you kindly refer us to any articles on central heating plants, and answer any of the following points.

1. What amount of steam can be conducted by steam pipes for a difference in pressure of 2, 5 and 10 pounds between supply and return ends when the pressures are 60 or more pounds?

2. Same for water return mains, when they discharge into open tanks, and pressure is 10 pounds and under.

Above are far long distances 200, 400, 600 and 1,000 feet.

3. Do you consider expansion joints sleeve pattern preferable to offsets or loops?

4. In case an expansion joint is used, would not an all cast iron one, which would become coated with magnetic oxide, be preferable to present method of brass and iron?

5. Would you consider it where mains run on a level more desirable to carry 5 pounds on heating apparatus discharging into return mains through simple trap in case pressure would return water, to using mechanical return traps, or tank and pump?"

[In reply to our correspondent we would say:

First.—THE ENGINEERING AND BUILDING RECORD has published accounts of the New York Steam Company's plant.

Second.—The Transactions of the Am. Soc. of C. E. contains papers by Mr. C. E. Emery on central steam plants. The secretary's office is No, 127 East Twenty-third Street, New York.

Third.—Robert Briggs' little book on steam heating, Van Nostrand publisher, give much valuable data on loss of heat or pressure in steam pipes. It has tables for conditions of low pressure steam.

Fourth.—Expansion joints are a nuisance, and never should be used if there is any way of getting along without them.

Magnetic oxide covered joints are impracticable. The slipping tube must be brass or gun metal.

The mechanical means of returning with pump and pump governor is the best, unless you can return by gravitation.]

CRACKED STEAM PIPES FROM WATER HAMMER.

ACCORDING to the London *Engineer*, five steam pipes were burst in England in 1889. Three of these were of cast iron, and their failure was attributed to the "water-hammer" action—*i. e.*, through the water therein, produced by condensation, not being properly drained off before steam was admitted. Two of these failures were accompanied by fatal results. In another case, a large copper pipe at an electric lighting works failed in a similar manner, causing the death of one person and injury to ten others. The workmanship in this case was stated to have been defective; but the failure was attributed chiefly to the action referred to. A steam pipe connected with some colliery boilers burst in a similar manner. Mr. Henry Hiller, Engineer to the National Boiler Assurance Company, very properly says: "All these cases manifest the great importance of steam pipes being arranged so that the liability to accumulation of water may be avoided. If this is unavoidable, special care should be taken to drain the pipes thoroughly before admitting the steam."

TRADE PUBLICATIONS.

HOT-WATER BOILERS.

THE Plaxton hot-water boiler is illustrated and described in a new catalogue recently issued by the Eureka Steam Heating Company, of Rochester, N. Y. General and detail views are given, together with a brief review of the subject of hot-water heating, and directions for setting the boiler.

BRIDGES AND ROOFS.

A HANDSOMELY illustrated catalogue has been issued by the Berlin Iron Bridge Company, of East Berlin, Conn. The illustrations represent a variety of structures put up by the company at different places, and give a good idea of the classes of work done by them. They were prepared direct from drawings or photographs and show exactly how the structures were built.

LINK BELT MACHINERY.

WITHIN the past six or seven years important developments have been recorded in the different kinds of conveying machinery, not the least interesting of which have been in connection with link belting. The different uses to which this product may be successfully applied are well illustrated in a pamphlet published a short time ago by the Link Belt Engineering Company, of Philadelphia, Pa. It is profusely illustrated, and besides matter of purely descriptive character gives also tables of sizes and prices of the different appliances.

PYROGRANITE is the name of a new artificial stone of Russian origin. It is made by mixing ordinary and refractory clays in different proportions, according to the uses to which it is to be put, molding them into desired shape, and finally roasting in a furnace.

ACCORDING to foreign reports, a great impetus has of late been given to the cement industry in Sweden. Among others a large manufactory has been erected on the Island of Gothland, the first industrial establishment of any importance on the island. There are six mills, each capable of producing between three and four barrels of raw cement per hour.

Novelties.

Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

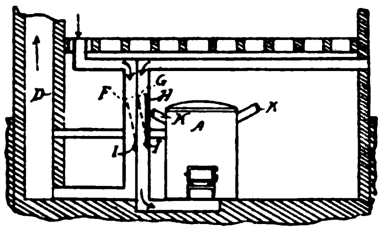
In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course be understood that the selection does not imply indorsement.

SWITCH GATE FOR HOT AIR FLUES.

IN the accompanying diagram A is a hot air heater which receives external fresh air through conduit B, and delivers it, warmed, to the room L through pipes K K, etc. C is a ventilating flue through which the air is ordinarily removed from the room thus heated to the shaft D. Flues B and C are at some point placed adjacent, and a section, F, of the partition wall between them is connected at H with a corresponding piece G, and both G and F are hinged to move freely about I I as axes.

Usually they are set as shown by full lines, both flues thus remaining distinct and operating separately. If, however, it be desired to keep up a continuous circulation of the same air, heating and reheating it without admitting more cold air, the switch gate F G H is revolved to the position indicated by the broken lines, and returns the air from the ventilating flue C, through B, to the furnace chamber, and back through pipes K K, at the same time that it shuts off the admission of outside air through the upper part of B. This arrangement is applicable to rooms continuously heated at times when they are not in use, as for churches, theaters, etc., before the admission of the audience. The same air, then remaining pure, may be maintained thus at a constant or increasing temperature.



The device is patented by Hosea B. Dewey, Milwaukee, Wis.

THE Town Council of Clonmel, Ireland, have adopted a water-works and sewerage scheme drawn by Mr. W. H. Radford, of Angel Road, Nottingham. The population of the town is 12,000, and the total cost of the two schemes £19,000, respectively £8,000 and £11,000. Mr. Radford proposes to bring water by gravitation from a mountain stream, with a water-shed of some 1,700 acres, at a distance of some three miles from the town. The water is stored, after passing through filter beds, in a covered reservoir on a hill in the vicinity of the town. It is estimated that the delivery at the reservoir will be 548,600 gallons per day. For the sewerage the proposal is also for gravitation, the existing system being adapted for taking surface water to the river. Centrifugal pumps will lift the sewage from the storage tanks transferring it to precipitating tanks, after which it will be passed through filter beds, and the effluent passed off into the Suir. Sufficient storage will be afforded by a chamber underneath the pumps to contain the sewage flowing through the night.

BOOK NOTICES.

CHALLEN'S ENGINEER'S LOG BOOK OF DAILY RUNS. Published by Howard Challen, New York. Price, flexible covers, 75 cents; half roan, $1.

The above heading practically tells nearly all there is to be said of the little book. The different pages are ruled so as to make blank tables, and have headings giving the month, day of the week, average gauge pressure, number of hours run, vacuum, piston speed and revolutions, indicated horse-power, temperature of hot well, water per horse-power per hour, etc. The desirability of keeping records of this kind and the convenience of the blanks offered are obvious. The book will save the labor of ruling the blanks and has the further advantage of keeping the records together for easy reference. There is a leaf for each week in the year.

THE fifty-ninth annual exhibition of the American Institute, of New York, opened on October 1, and will continue until the end of November.

THE NEW RIVER AND HARBOR BILL

THE following is a revised copy of the River and Harbor Bill as signed by President Harrison September 19.

A list of the places at which the Secretary of War has been directed to cause examinations to be made, with a view of making improvements, will be published in a subsequent issue.

MAINE.

Improving harbor at Rockland, continuing improvement, $37,500; improving harbor at York, continuing improvement, $10,000; for the construction of a breakwater from Mount Desert to Porcupine Island, continuing improvement, $50,000; improving harbor at Portland, continuing improvement, $40,000; improving harbor at Camden, continuing improvement, $6,000; improving harbor at Back Cove, Portland Harbor, continuing improvement, $25,000; improving harbor at Rockport, completing improvement, $5,000; improving Moose-a-bec Bar, continuing improvement, $15,000; improving harbor at Belfast, $10,000.

Improving Bagaduce River, continuing improvement, $4,000; improving Penobscot River, continuing improvement, and for dredging near Stern's mill, $25,000; improving Narragaugus River, continuing improvement, $7,500; improving Kennebec River, continuing improvement, $50,000; improving Saco River, continuing improvement, including breakwater and the construction of a proposed jetty opposite the same, $65,000: *Provided*, That the whole of said sum may be used in the discretion of the Secretary of War in the construction of said proposed jetty; improving Harrisseckit River, $10,000; improving Saint Croix River, $35,000, but upon the condition that the Goverment of the Dominion of Canada shall expend a like sum in the improvement of said river; improving Kennebunk River, at or near its mouth, $20,000, the entire amount to be expended in repairs if necessary; improving Pleasant River, to complete improvement, $3,500.

NEW HAMPSHIRE.

Improving Portsmouth Harbor, to complete improvement, $13,000; improving harbor of refuge at Little Harbor, continuing improvement, $40,000.

Improving Bellamy River, continuing improvement, $10,000; improving Cocheco River, $25,000.

VERMONT.

Improving harbor at Burlington, for repairs, $20,000; improving harbor at Gordon's Landing, Lake Champlain, to complete breakwater, $6,000; improving Otter Creek, continuing improvement, $5,000,

MASSACHUSETTS.

Improving harbor at Boston, continuing improvement, $145,000, of which sum $7,000 to be used in widening Nantasket Beach Channel, $25,000 in extending main ship channel, and $20,000 for continuing improvement of Charles River, provided, that no expenditure of said $20,000 shall be made until the draws in the Arsenal Street and Market Street bridges shall be made to conform to the projected channel without cost to the United States; improving harbor at Lynn, continuing improvement, $15,000; improving harbor at Nantucket, continuing improvement, $25,000; improving harbor at Newburyport, continuing improvement, $25,000; improving harbor at Plymouth, continuing improvement and repairs of work on Long Beach, $8,000; improving harbor at Provincetown, completing existing project, $7,500; improving harbor at Scituate, continuing improvement, $10,000; improving harbor at Gloucester, continuing improvement, $15,000; improving harbor at Wareham, continuing improvement, $5,000; improving harbor at New Bedford, continuing improvement, $10,000; improving harbor at Hingham, continuing improvement, $5,000; improving harbor at Winthrop, continuing improvement, $5,000; improving harbor at Hyannis, continuing improvement, $8,000; improving harbor at Vineyard Haven, continuing improvement, $10,000; improving harbor at Wellfleet, continuing improvement, $4,000; improving national harbor of refuge at Sandy Bay, Cape Ann, continuing improvement, $150,000; improving harbor at Manchester, continuing improvement, $5,000; improving Martha's Vineyard inner harbor at Edgartown, for dredging, $2,000; improving Salem Harbor, including South River, $14,000; improving Stage Harbor at Chatham, $5,000; improving Westport Harbor and East and West Branch of Westport River, $1,000, to be applied in extending the jetty on Horse Neck Point and to dredging in Westport Harbor.

Improving Powow River, continuing improvement, $5,000; improving Taunton River, continuing improvement, $7,000; improving Merrimac River at Mitchell's Falls, continuing improvement, $10,000; improving Weymouth River, $10,000.

RHODE ISLAND.

Improving Pawtucket River, continuing improvement, $30,000; improving Providence River and Narragansett Bay, continuing improvement, $50,000; improving Green Jacket Shoal, Providence River, continuing improvement, $25,000; improving Pawcatuck River, completing improvement, $16,600.

Improving harbor at Block Island, continuing improvement, $15,000; improving harbor at Newport, continuing improvement, $12,500; improving harbor at Greenwich Bay, to complete, $2,000; improving cove near southeast extremity of Coaster's Harbor Island, and water-way between said island and Rhode Island, to complete, $5,500; constructing national harbor of refuge at or near Point Judith, commencing construction, $75,000.

CONNECTICUT.

Improving harbor at Bridgeport, continuing improvement, $20,000, of which $15 000 shall be expended in constructing breakwater between the Tongue and inner beacon, and $5,000 to complete improvement above the bridge; improving harbor at Black Rock, continuing improvement, $5,000; constructing breakwaters at New Haven, in accordance with the plans submitted by Chief of Engineers in report for 1889, continuing improvement, $120,000; improving harbor at New Haven, continuing improvement, $15,000; improving harbor at Norwalk, completing improvement, $4,000; improving harbor at Wilson's Point, for widening and deepening channel, $30,000; improving harbor at Stonington, continuing improvement, $12,500; improving harbor at Stamford, completing improvement, $5,000; improving harbor at Five Mile River, continuing improvement, $5,000; improving harbor at Milford, completing improvement, $2,500; improving harbor of refuge, Duck Island Harbor, on Long Island Sound, $25,000; improving harbor at Clinton, continuing improvement, $3,500.

Improving Connecticut River below Hartford, continuing improvement, $12,500; improving Housatonic River and for breakwater, continuing improvement, $35,000; improving Thames River, continuing improvement, $20,000, which may be expended at any point between Norwich and New London; improving Mystic River, $10,000.

NEW YORK.

Improving harbor at Buffalo, continuing improvement, $300,000 for continuance of concrete construction and repairs and extension of breakwater; improving breakwater at Rouse's Point, continuing improvement, $15,000; improving harbor at Canarsie Bay, continuing improvement, $5,000; improving harbor at Charlotte, continuing improvement, $25,000; improving harbor at Dunkirk, continuing improvement, $20,000; improving harbor at Flushing Bay, continuing improvement, $20,000; improving channel at Gowanus Bay, continuing improvement, $60,000; improving Bay Ridge Channel in Gowanus Bay, by dredging, $100,000; improving harbor at Great Sodus Bay, continuing improvement, $10,000; improving harbor at Little Sodus Bay, continuing improvement, $13,000; improving harbor at Greenport, continuing improvement, $5,000; improving harbor at Oak Orchard, continuing improvement, $5,000; improving harbor at Ogdensburg, continuing improvement, $42,000, including new project; improving harbor at Olcott, continuing improvement, $30,000; improving harbor at Oswego, continuing improvement, $30,000; improving harbor at Rondout, repairing existing works, $5 000; improving Tonawanda Harbor and Niagara River, continuing improvement, $75,000; improving New York Harbor, completing improvement, $160,000; improving harbor at Saugerties, continuing improvement, $10,000; improving harbor at Port Chester, continuing improvement, $5,000; improving harbor at Glen Cove, continuing improvement, $15,000; improving harbor at Pultneyville, $2,000; improving channel between Staten Island and the New Jersey shore, New York and New Jersey, continuing improvement, $15,000; improving Arthur Kill, between Staten Island and the New Jersey shore, New York and New Jersey, dredging and straightening channel near Staten Island Bridge, and removing the point of land westerly of same, $7,000; improving harbor at Port Jefferson Inlet, $25,000; improving harbor at Plattsburg, for repairs and extension of breakwater, to complete, $32,500; improving harbor at Larchmont, on Long Island Sound, $5,000; improving harbor at Huntington, Long Island, $10,000.

Improving Hudson River, continuing improvement, $150,000; improving Newtown Creek and Bay, continuing improvement, $35,000; improving East River and Hell Gate, removing obstructions, $200,000; improving Harlem River, continuing improvement, $250,000; and the Secretary of War is directed to cause the low bridges now crossing said Harlem River to be replaced by other bridges at the expense of the owners thereof as soon as the necessary legislation, if any such legislation be necessary, shall have enabled the change in grade to the approaches of said bridges, thus required, to be made, the owners of said bridges being allowed a reasonable time in which to complete the work necessary for said approaches. Said bridges shall leave a clear space, between the under sides thereof and the high water of spring tides, of 24 feet, and shall be provided with draw spans and draws of the width and length to be determined by the Secretary of War, and shall in all respects comply with this law and conform to the requirements of the Secretary of War: *Provided*, That, the Secretary of War shall prescribe the times and regulations for the opening and operating of the draws in said bridges; improving Grass River, completing improvements, $6,000; improving Great Chazy River, from its mouth on Lake Champlain to Champlain Village, $10,000; improving Patchogue River, $15,000; improving Ticonderoga River, continuing improvement, $2,000; improving Wappinger's Creek, from the falls to its mouth, $13,000; improving Brown's Creek, Sayville, Long Island, $12 000; improving shoal between Sister Islands and the Cross over light, St. Lawrence River, $5,000.

NEW JERSEY.

Improving Passaic River above Newark, continuing improvement, $5,100, $1,500 of which, or so much thereof as may be necessary, shall be expended in making an examination and survey of said river; improving Maurice River, continuing improvement, $8,000; improving Passaic River below Newark, continuing improvement, $40,000; improving Raritan River, continuing improvement, $50,000; improving Shrewsbury River, continuing improvement, $10,000, half of which shall be expended on the South Branch; improving South River, continuing improvement, $5,000; improving Squan River, by the removal of obstructions placed by the Government at the mouth of said river, if, in the discretion of the Secretary of War, the same should be done, $2,000; improving Shoal Harbor and Compton's Creek, so as to give a channel 4 feet deep at mean low water, $5,000; improving Elizabeth River, $5,000; improving Mattawan Creek, $2,500; improving Alloway Creek, $6,000.

Improving harbor at Raritan Bay, continuing improvement, $40,000, one-half of which may be used in dredging bar between South Amboy and Great Beds Light.

PENNSYLVANIA.

Improving harbor at Erie, continuing improvement, $40,000; improving the harbor of Philadelphia, for removal of Smith's Island and Windmill Island, in the State of Pennsylvania, and Petty's Island, in the State of New Jersey, or such parts of them and the shoals adjacent thereto as may be required, and for the improvement of the harbor between the cities of Philadelphia, Pa., and Camden, N. J., $200,000: *Provided*, That contracts may be entered into by the Secretary of War for the work required for the improvement of the Delaware River between the cities of Philadelphia, Pa., and Camden, N. J., according to the plan reported by the Board of Engineers and transmitted to Congress April 7, 1888, also: *Provided*, That the cost of the improvement shall not be thereby increased, to be paid for as appropriations may from time to time be made by law; improving ice-harbor at Marcus Hook, continuing improvement, $5,000.

Improving Allegheny River, continuing improvement, $20,000; improving Schuylkill River, continuing improvement, $45,000; improving Delaware River, Pennsylvania and New Jersey, continuing improvement from Trenton to its mouth, $250,000, $10,000 of which shall be expended in continuing improvement on the Rancocas River, one of the tidal tributaries of said river; for continuing construction of the dam at Herr's Island in Allegheny River, near Pittsburg, $35,000; improving the Ohio River by the construction of a movable dam at or below the mouth of Beaver River, at such locality as the Secretary of War may consider most advantageous, $250,000.

OHIO

Improving harbor at Ashtabula, continuing improvement, $40,000, improving harbor at mouth of Black River, continuing improvement, $12,000; improving harbor at Cleveland, continuing improvement, $75,000; improving harbor at Fairport, continuing improvement, $30,000, of which $8,700 may in the discretion of the Secretary of War be expended in dredging and deepening the channel of Grand River from its mouth to the new docks on the west side of the same; improving harbor at Huron, continuing improvement, $16,000; improving harbor at Sandusky, continuing improvement, $45,000; improving harbor at Toledo, continuing improvement, $200,000; improving harbor at Toledo, for clearing the old channel, $5,000; for ice harbor at the mouth of Muskingum River, for repairs, $30,000; improving harbor at Port Clinton, continuing improvement, $3,000; improving harbor at Vermillion, for preservation of piers, $2,000.

Improving Sandusky River, $1,500.

DELAWARE.

Improving Delaware Breakwater, continuing improvement, $80,000; improving ice-harbor at New Castle, completing improvement, $8,100; improving harbor at Wilmington, continuing improvement, $30,000. The Secretary of War is directed to appoint a commission of three persons, one of whom shall be a civil engineer of experience in the improvement of rivers and harbors, who shall proceed to make an accurate survey of the tidal streams which form the harbor of Wilmington, Del., making all necessary observations to obtain all the data required for a plan for the permanent improvement of the harbor to suit the present and prospective wants of commerce and navigation; and that said commissioners shall, as soon as possible, make to the Secretary of War a report, submitting with it a plan for the improvement of said harbor.

Improving Appoquinnimink River and the mouth of the same, $5,000, improving Smyrna River, continuing improvement, $5,000.

MARYLAND.

Improving Choptank River, continuing improvement, $7,500; improving Susquehanna River, Maryland and Pennsylvania, continuing improvement, $4,000, to be expended above the Philadelphia, Wilmington and Baltimore Railroad Bridge; improving Fairlee Creek or Inlet, continuing improvement, $5,000; improving Patuxent River, continuing improvement, $6,000; improving Wicomico River, $10,000; improving Manokin River, $7,500; improving Chester River, $5,000, from Crumpton to Jones' Landing; improving Elk River, $10,000; improving North East River, Maryland, $2,500

Improving harbor at Baltimore, continuing improvement, $340,000; improving harbor at Breton Bay, continuing improvement, $5,000; improving harbor at Cambridge, continuing improvement, $5,000.

DISTRICT OF COLUMBIA.

Improving Potomac River at Washington, continuing improvement, $280,000, of which $20,000, or so much thereof as may be necessary, may be expended on the channel in the Eastern Branch between the navy yard and Giesborough Point.

VIRGINIA.

Improving Appomattox River, continuing improvement, $15,000; improving Chickahominy River, continuing improvement, $2,500; improving James River, continuing improvement, $200,000: *Provided*, That $3,500 of this amount, or so much thereof as may be necessary, may be expended in the discretion of the Secretary of War in removing the bar at the mouth of Turkey Island, Creek or Bayou; improving Mattaponi River, continuing improvement, $3,000, $1,500 of which may be expended above Ayletts; improving channel at Mount Vernon, to complete, $2,500; improving Nomini Creek, continuing improvement, $5,000; improving Pamunkey River, continuing improvement, $3,000; improving Rappahannock River, continuing improvement, $15,000; improving Staunton River, continuing improvement, $8,000 on the consolidated project; improving Urbana Creek, continuing improvement, $3,000; improving York River, continuing improvement, $30,000; improving by dredging and otherwise the inland water-way from Chincoteague Bay, Virginia to Delaware Bay at or near Lewes, Delaware, to be used from Chincoteague Bay to Delaware Bay, continuing improvement, $50,000, no part of which shall be expended until the right of way is secured free of cost to the United States; improving Nansemond River, continuing improvement, $10,000; improving Hampton Creek and Bar, to complete improvement, $10,000; improving Occoquan Creek, $10,000; improving Acquia Creek, $10,000.

Improving harbor at Norfolk and its approaches, continuing improvement, $150,000, $50,000 of which shall be expended in improving the approach to the inner harbor and the United States Navy-Yard at Norfolk, by increasing anchorage between Lambert's Point and Fort Norfolk; improving harbor at Cape Charles City and approaches by Chenton Inlet, $25,000, for dredging only; improving harbor at Onancock, $6,000.

WEST VIRGINIA.

Improving Big Sandy River and Kentucky, to complete improvement, $31,000; improving Elk River, continuing improvement, $2,500; improving Buchannon River, continuing improvement, $1,000; improving Great Kanawha River continuing improvement, $300,000; improving Guyandotte River, to complete improvement, $2,000; improving Little Kanawha River, to complete projected lock and dam, $40,000, but no toll shall be collected by any person or corporation for this improved navigation, and such right, if any exist, shall be relinquished in a manner satisfactory to the Secretary of War before the expenditure of any of the money herein appropriated for this work; improving Gauley River, continuing improvement, $3,000; improving Cheat River, to complete improvement, $13,000.

KENTUCKY.

Improving Kentucky River, continuing improvement, $108,000; improving the Ohio River, continuing improvement, $300,000, of which sum $7,500 shall be expended in constructing an ice-pier pursuant to the present or prospective plan of the Chief of Engineers, at or near the mouth of Kerr's Run, in Ohio: *Provided*, That the Secretary of War is hereby authorized and directed to obtain, if he can do so without cost to the United States, a perpetual lease or conveyance of the riparian rights of the property owners at said locality, in the event said ice-pier shall be located where there is no landing place: *And provided further*, That at said locality, if it be an improved landing, he shall first obtain a relinquishment of wharfage right and dues in favor of water craft seeking protection from damage by ice; and no part of this appropriation shall be used for such purpose until the foregoing conditions are complied with; and a like sum for like purposes upon similar terms in all respects may be used in the discretion of the engineer in charge of the Ohio River at Ripley, O., and at Portsmouth, O.; and $20,000 of said Ohio River appropriation may be used for continuation of harbor improvement at Madison, Ind., according to the plans heretofore submitted by Lieutenant-Colonel Merrill; $13,250 may be expended in the completion of the construction of the embankment on the south side of the Great Miami River near its junction with the Ohio to confine the waters of said Miami River in great floods to the general course of its channel at or near the Ohio, to the end that the formation of the bar in the Ohio now obstructing navigation may be arrested; and $15,000 may be expended in completing the embankment at Shawneetown, already partly constructed for the preservation of the harbor at that place; the further sum of $20,000 may be expended for the removal of rock obstruction at the mouth of Licking River; improving the Falls of the Ohio River, continuing improvement, $60,000; improving Indiana Chute Fall, Ohio River, continuing improvement, $25,000; improving Licking River, from Farmer's to West Liberty, continuing improvement, $3,000; improving Rough River, $25,000, to be expended in procuring the necessary land, commencing the construction of a lock and dam, and removing obstructions in the river from its mouth to Hartford, Ky., on the least expensive-estimate recommended by Captain James C. Post, Corps of Engineers.

Improving Tug Fork of Big Sandy River and West Virginia, for snagging and the removal of other obstructions, $2,500: improving Levisa Fork of Big Sandy River, for snagging and the removal of other obstructions, $2,500.

NORTH CAROLINA.

Improving Cape Fear River, above Wilmington, continuing improvement, $15,000; improving Cape Fear River at and below Wilmington, $170,000; improving Contentnia Creek, continuing improvement, $7,000; improving inland water route from Norfolk Harbor, Virginia, to Albemarle Sound, through Currituck Sound, continuing improvement, $10,000; improving Neuse River, up to Smithfield, continuing improvement, $20,000: improving New River, continuing improvement, $5,000; improving Pamlico and Tar Rivers, including the Tar River from Tarboro to Little Falls, continuing improvement, $10,000: improving Trent River, continuing improvement, $5,000; improving Lumber River and South Carolina, continuing improvement, $5,000; improving Roanoke River, continuing improvement, from its mouth to Clarksville, $25,000; improving Yadkin River, up to Bailey's Ferry, continuing improvement, $5,000; improving Ocracoke Inlet, $90,000; improving Mackey's Creek, $15,000 to complete the project for nine feet depth of channel; improving North East (Cape Fear) River, so far as to clear out its natural obstructions from Wilmington up to Kornegay's Bridge, $5,000; improving water way between New River and Swansboro, $5,000; improving Lockwood's Folly River, $5,000; improving Fishing Creek, from its mouth to Bellamy's Mill, so far as to remove its natural obstructions, $10,000: *Provided*, That no part of this sum shall be expended until the bridges over that part of said river to be improved have been removed or suitable draws have been provided in the same, so as not to obstruct the navigation of said river. Improving Pasquotank River, $3,000.

Improving harbor at Beaufort, continuing improvement, $15,000; improving the inland water-way between Beaufort and New River, continuing improvement, $15,000.

LOUISIANA.

Improving Amite River and Bayou Manchac, completion of old project, $3,800: *Provided*, That this sum may be expended upon the Manchac or Amite in such proportions as the engineers may deem best; improving Boeuf River, continuing improvement, $5,000; improving Bayou Bartholomew, and Arkansas, continuing improvement, $5,000; improving Bayou Courtableau, completing improvement, $2,200; improving Bayou D'Arbonne, continuing improvement, $2,000; improving Tensas River and Bayou Macon, continuing improvement, $5,000; improving Tickfaw River, to complete $1,000; improving Bayous Rondeway and Vidal, re-opening old bayou, $1,000; improving Bayou Plaquemine, continuing improvement, $100,000; improving Bayou Lafourche, including immediate dredging to secure low water navigation, $50,000; improving Red River, Louisiana and Arkansas, from Fulton, Ark., to the Atchafalaya River, continuing improvement, $100,000, of which $15,000 shal be used in the work at Alexandria, $20,000 in deepening and widening that portion of the river known as Little River, from the Scoping Cut-off to Knox Point, and $5,000 in closing what is called the Sale and Murphy Outlet, or canal, on the west bank of the River above Shreveport; for completion of survey of Red River from Fulton, Ark., to the Atchafalaya River, $28,000; improving Bayou Teche from the mouth to St. Martinsville, $5,000; improving Bogue Chitto, $5,000; to be expended from its mouth to where the first bridge obstructing navigation is located; improving Tchefuncte and Bogue Phalia, for removal of snags, trees and obstructions, $1,000.

Improving mouth and passes of Calcasieu River, $75,000.

MICHIGAN.

Improving Saginaw River, continuing improvement, $75,000, $37,500 of which shall be expended above Bay City; improving Saint Mary's River at the Falls, continuing improvement on new locks and approaches, $900,000. *Provided*, That such contracts as may be desirable may be entered into by the Secretary of War for materials and labor for the entire structure and approaches, or any part of the same, to be paid for as appropriations may from time to time be made by law; improving Hay Lake Channel, continuing improvement, $4,000: *Provided*, That such contracts as may be desirable may be entered into by the Secretary of War for materials and labor for the entire work, or any part of the same, to be paid for as appropriations may from time to time be made by law; improving Saint Clair Flats Ship-Canal, continuing improvement, $80,000; improving Clinton River, continuing improvement, $10,000; improving Saint Joseph River, completing improvement, $1,000; improving mouth of Black River, continuing improvement, $10,000; improving Rouge River, at its junction with Detroit River, and up the river as far as the bridge of Saint Louis and Wabash Railroad, $10,000: improving Thunder Bay River, Alpena, for 16-foot channel from mouth to one mile above, $10,000; improving Black River, at Port Huron, to deepen channel, $25,000; improving Menomonee River, Michigan and Wisconsin, continuing improvement up the river from termination of old work, $54,000.

Improving harbor at Charlevoix and entrance to Pine Lake, continuing improvement, $9,000; improving harbor at Frankfort, continuing improvement, $10,000; improving harbor at Grand Haven, continuing improvement, $75,000; improving harbor of refuge at Grand Marais, continuing improvement, $50,000; improving harbor at Manistee, continuing improvement, $50,000, improving harbor at Black Lake, continuing improvement, $10,000; improving harbor at Monroe, continuing improvement, $5,000; improving harbor at Muskegon, continuing improvement, $50,000, $34,000 of which to close gap as recommended by engineer in charge; improving harbor at Ontonagon, continuing improvement, $10,000; improving harbor at Pentwater, continuing improvement, $8,000: improving harbor of refuge at Portage Lake, continuing improvement, $8,000; improving harbor of refuge at Sand Beach, for repairs, custody, and control of harbor and dredging the same, $30,000; improving harbor at Saint Joseph, continuing improvement, $20,000, $5,000 of which shall be expended on the water channel leading to Benton Harbor; improving harbor at South Haven, continuing improvement, $15,000; improving harbor at White River, continuing improvement, $17,000; improving harbor at Marquette, continuing improvement, $40,000; improving harbor at Thunder Bay, to restore 14-foot channel, $5,500; improving harbor at Petoskey, for breakwater and harbor of refuge, $15,000.

WISCONSIN.

Improving harbor at Ahnapee, continuing improvement, $6,000; improving harbor at Green Bay, continuing improvement, $10,000; improving harbor at Kenosha, continuing improvement, $17,500, $2,500 of the above appropriation to be expended in dredging the inner harbor; improving harbor at Kewaunee, continuing improvement, $20,000; improving harbor at Manitowoc, completing improvement, $8,000; and the engineer in charge, with the approval of the Secretary of War, may use such part of the above appropriation in the construction of an outer breakwater as he may deem proper; improving harbor of refuge at Milwaukee, continuing improvement, $80,000; improving harbor at Milwaukee, continuing improvement, $6,000: improving harbor at Port Washington, continuing improvement, $3,000; improving harbor at Racine, continuing improvement, $17,500; improving harbor at Superior Bay and Saint Louis Bay, continuing improvement, $65,000; improving harbor at Sheboygan, continuing improvement, $15,000; improving harbor at Ashland, continuing improvement, $60,000; improving harbor at Two Rivers, continuing improvement, $3,000; improving Sturgeon Bay Canal harbor of refuge, for maintenance of channel and piers, $3,000; improving Minnesota Point at Superior, for the preservation of said point and the protection of the harbor at Superior Bay by the construction of sand fences, $4,895.

Improving Chippewa River including Yellow Banks, continuing improvement, $10,000; improving Fox River, below Portage, except as herein provided, continuing improvement, $100,000, of this sum $5,000, or so much thereof as may be necessary, shall be used for deepening the south outlet of Lake Winnebago, at Neenah, so as to make navigation practicable during low-water season; the sum of $8,000, or so much thereof as may be necessary, shall be used for removing the sand bar at outlet of Fond du Lac River, according to recommendations in report of Major Charles E. L. B. Davis, Major of Engineers; improving Saint Croix River, Wisconsin and Minnesota, continuing improvement, $8,000.

INDIANA.

Improving outer harbor at Michigan City, continuing improvement, $50,000; improving inner harbor at Michigan City, continuing improvement, $7,500, of which $2,500 may be expended for a new dump scow.

INDIANA AND ILLINOIS.

Improving Wabash River, Indiana and Illinois, above Vincennes, continuing improvement, $5,500; improving Wabash River, Indiana and Illinois, below Vincennes, continuing the work on Lock and dam at Grand Rapids, near Mount Carmel, Ill., $60,000, including snagging, and $6,000 of said sum may be expended on said river at or near Grayville in the State of Illinois; improving White River, Indiana, the $5,000 heretofore appropriated is hereby directed to be expended, notwithstanding the conditions upon which such appropriation was made; improving Calumet River, Illinois and Indiana, continuing improvement, $50,000; that the city of Galena, Ill., be and hereby is, authorized to continue and complete the improvement and navigation of the channel of Galena River from a point 800 feet below the Custom House in said city to the main channel of the Mississippi River upon conditions hereinafter mentioned: *Provided*, That unless said city or her representatives shall commence the work within one year and secure a navigable channel within five years from the approval of this act, the provisions herein shall be null and void. In carrying out the provisions of this act, the city of Galena or her representatives shall be authorized to construct a dam above the point to be opened for navigation, rising not more than 12 feet above low water or a like dam may be constructed below the point to be opened to navigation with a lock not less than 280 feet long and 52 feet wide.

ILLINOIS.

Improving Illinois River, continuing improvement, $2,000; improving the Kaskaskia River, from the mouth to Baldwin Bridge, $6,000; for the construction of the Illinois and Mississippi Canal to connect the Illinois River at a point near the town of Hennepin with the Mississippi River, at the mouth of Rock River, together with a branch canal or feeder from said Rock River to the main line of said canal, $500,000; for continuing operations upon the reservoirs at the head waters of the Mississippi River, $80,000, to be expended in accordance with the recommendations of the Chief of Engineers in his annual report for the year 1889; improving the Mississippi River above St. Anthony's Falls, continuing improvement. $18,000; improving the Mississippi from the landing on the west bank below the Washington Avenue Bridge, Minneapolis, to the Des Moines Rapids, continuing improvement, $500,000, of which sum $30,000, or so much thereof as may be necessary, shall be expended by the engineers in charge in removing the sand bars and other obstructions to navigation in the East Channel of the Mississippi River opposite the prairie, on which the city of Prairie du Chien, in the State of Wisconsin, is located, the same being between Minneapolis and Des Moines Rapids; of which sum also $50,000 shall be expended between the Chicago, St. Paul, Minneapolis and Omaha Railroad bridge at St. Paul and the Washington Avenue bridge, Minneapolis, in dredging, removal of gravel, boulders and broken rock and the construction of dams and revetments; and in the discretion of the Secretary of War, the sum of $5,000, or so much thereof as may be necessary, shall be expended in removing the bar in the river at Port Bryon, in the State of Illinois; $5,000 at Burlington, Iowa, and $2,000 at Montrose, Iowa; improving the Mississippi River at Des Moines Rapids Canal, for completion of existing project, $22,000; improving Mississippi River, from Des Moines Rapids to the mouth of the Illinois River, $165,000, out of which $25,000 shall be expended in continuing the dredging in Quincy Bay, in the State of Illinois, and the Secretary of War is authorized and directed to cause an examination and report to be made by a competent engineer upon the advisability of reopening Willow Slough, or some other channel, from the Mississippi River to Quincy Bay; and also $15,000 of said sum shall be used in the rectification of the river at Clarksville, Mo., as suggested in the report of Captain Ruffner; and also $25,000 of said sum, or so much thereof as may be necessary, may be expended at the discretion of the Secretary of War to protect the banks of the river from erosion and prevent the destruction of the embankment of the Sny Island levee; improving the Mississippi River, from the mouth of the Illinois River to the mouth of the Ohio River, and, at the discretion of the Secretary of War, the protection of the Illinois shore opposite the mouth of the Missouri River, $400,000, $50,000 of which shall be expended in completing the work at Alton, and $50,000 in improving the river at St. Genevieve, in the State of Missouri.

Improving harbor at Calumet, continuing improvement, $20,000; improving harbor at Chicago, continuing improvement, $100,000; improving harbor at Waukegan, continuing improvement, $35,000.

ALABAMA.

Improving Alabama River, continuing improvement, $20,000; improving Black Warrior River, from Tuscaloosa to Daniel's Creek, continuing improvement, $150,000; improving Tallapoosa River, maintaining existing works, $4,000; improving Cahawba River, the existing provision restricting the expenditure of the balance now available for the improvement of said river is hereby repealed, and said balance shall be expended in continuing the improvement thereof; improving Tombigbee and Warrior Rivers, extending improvement, $100,000, of which $55,000 to be expended on the Tombigbee and $45,000 on the Warrior; so much of said sums as may be necessary is authorized to be expended in acquiring by purchase or condemnation under the laws of Alabama, the lands needed in making such improvements; improving Tombigbee River from Demopolis to Columbus, Miss., extending improvement, $15,000; improving Tombigbee River from Walker's Bridge to Fulton, continuing improvement, $4,000; improving Tombigbee River from Fulton to Vienna; continuing improvement, $6,000.

Improving harbor at Mobile, up to the mouth of Chickasabogue Creek, continuing improvement, $350,000.

SOUTH CAROLINA.

Improving Edisto River, continuing improvement, $5,000, which shall be expended in equal sums in the north and south forks of said river; improving Great Pee Dee River, continuing improvement, $12,500; improving Salkiehatchie River, to complete existing project, $5,000; improving Santee River, continuing improvement, $30,000, to be used in snagging and in making new cut between Estherville and Minim Creek, as recommended by the engineer in charge of the improvement of said river; improving Waccamaw River to Waccamaw Lake, North Carolina to South Carolina, continuing improvement, $12,500; improving Wapoo Cut, continuing improvement, $10,000; improving Wateree River, completing improvement, $12,500: *Provided*, That no part of said appropriation shall be expended until the Wilmington, Columbia and Augusta Railroad Company and the Camden branch of the South Carolina Railroad Company shall have built suitable draw-spans in their bridges over said river, to be approved by the Secretary of War. Improving Congaree River, continuing improvement, $5,000: *Provided*, That no part of said appropriation shall be expended until the South Carolina Railroad Company have built a suitable draw-span in its bridge over said river, to be approved by the Secretary of War. Improving Mingo Creek, continuing improvement, $5,000; improving Clark's River, continuing improvement, $2,500; improving Little Pee Dee River, continuing improvement, $5,000; improving Beaufort River, or that part of it known as Brickyard Creek, at the point called Brickyard, near Coosaw Mouth, $12,500.

Improving harbor at Charleston, including Sullivan's Island, continuing improvement, $370,000, of which $5,000 shall be expended on Mount Pleasant shore of inner harbor of Charleston; improving harbor at Georgetown, continuing improvement, $8,000; improving Winyaw Bay, continuing improvement, $100,000.

GEORGIA.

Improving Altamaha River, continuing improvement, $15,000; improving Chattahoochee River, Georgia and Alabama, continuing improvement, $20,000; improving the Coosa River in Georgia and Alabama, between Rome, in Georgia, and the East Tennessee, Virginia and Georgia Railroad Bridge, in Alabama, continuing improvement under approved existing project, $150,000; also for improving said river between Wetumpka, in Alabama, and said East Tennessee, Virginia and Georgia Railroad Bridge, work to be commenced at Wetumpka end, $150,000, of which so much as may be necessary is authorized to be expended in acquiring, by purchase or condemnation under the laws of Alabama, the lands needed in making such improvement, as the same become necessary; such improvement to be made in harmony with the existing approved project for the improvement of the Coosa River between Rome and said bridge; locks to be 40 feet wide and 210 feet between miter sills; improving Flint River, continuing improvement, $20,000; of which $5,000 are to be expended between Albany and Montezuma, and $15,000 below Albany; improving Ocmulgee River, continuing and extending improvement, $30,000, of which $15,000 are to be expended between Macon and Hawkinsville, and $15,000 between Hawkinsville and its mouth; improving Oconee River, continuing and extending improvement, $25,000, of which $5,000 are to be expended between Milledgeville and the Central Railroad Bridge; improving the Savannah River, between Augusta and Savannah, continuing improvement, $25,000; improving Jekyl Creek, continuing improvement, $7,500.

Improving harbor at Brunswick, continuing improvement, $35,000; improving Cumberland Sound, Georgia and Florida, continuing improvement, $112,500; improving harbor at Savannah, continuing improvement on extended project, $350,000; improving harbor at Darien, $25,000.

FLORIDA.

Improving harbor at Apalachicola Bay and the mouth of the river, continuing improvement, $20,000; improving harbor at Cedar Keys, continuing improvement, $2,500, a part of which may be expended at Derrick Island Gap on the inside channel from Suwanee River; improving harbor at Pensacola, continuing improvement, $25,000; improving harbor at Tampa Bay, continuing improvement, $25,000; improving entrance to harbor at Key West, $40,000; improving, dredging, and deepening the channel of Charlotte Harbor and Pease Creek, $35,000; improving harbor at Saint Augustine, to complete protection from erosion, $20,000; improving Apalachicola River, to maintain existing works, including Lee's Slough, $2,000; improving Choctawhatchie River, Florida and Alabama, continuing improvement under existing projects, and to secure low-water navigation between Geneva and Newton, $12,500: *Provided*, That no part of said sum shall be expended above Hollis' Bridge until a draw, approved by the Secretary of War, is put in said bridge; improving Escambia and Conecuh Rivers, Florida and Alabama, continuing improvement, $7,500; improving Manatee River, continuing improvement, $6,000; improving Saint John's River, from Jacksonville to the ocean including the channel over the bar at the mouth, continuing improvement, $170,000; improving Suwanee River, continuing improvement, $3,000; a part of which may be expended on the inside channel to Cedar Keys; improving Volusia Bar, for repairs, $500; improving Withlacoochee River, completing improvement, $5,400; improving Caloosahatchee River, to complete improvement, $3,600; improving La Grange Bayou, continuing improvement of Holmes River, $3,000; improving Ocklawaha River, to Leesburgh on Lake Griffin, $10,000; improving Sarasota Bay, from Tampa Bay to Sarasota, as recommended by W. M. Black, Captain of Engineers, $5,000.

TEXAS.

Improving Buffalo Bayou, continuing improvement, $25,000; improving Cedar Bayou, by removal of bar at the mouth of said bayou, where it empties into Galveston Bay, completing improvement, $18,150; improving Trinity River, continuing improvement, $10,000; the Secretary of War is hereby directed to cause a survey to be made of Cypress Bayou and the lakes between Jefferson, Tex., and Shreveport, La., in order to ascertain if the navigation of the said bayou and lakes can be materially and permanently improved by the construction of such dams, and locks and dams, as may be necessary, and if found practicable the probable cost thereof, and for this purpose the sum of $10,000, or so much thereof as may be necessary, is hereby appropriated.

Improving harbor at Sabine Pass, continuing improvement, $300,000, and of this amount the Secretary of War may, in his discretion, use $50,000, or so much of said $50,000 as may be necessary, for dredging; improving and maintaining ship-channel in Galveston Bay, from Bolivar Channel through Morgan's Cut and Morgan's Channel constructed through Morgan's Point to the San Jacinto River, $40,000; improving entrance to Galveston Harbor, continuing improvement, $500,000; *Provided*, That contracts may be entered into by the Secretary of War for such materials and work as may be necessary to carry out the plan contained in the report of the Chief of Engineers for 1886.

ARKANSAS.

Improving Arkansas River, Ark., Indian Territory, and Kansas, continuing improvement from Wichita, Kansas, to its mouth, $180,000; improving St. Francis River, continuing improvement, $4,000; improving Arkansas River, Ark., Indian Territory and Kansas, from Wichita, Kansas, to its mouth, for operating snag-boats and removing obstructions, $20,000; improving Red River above Fulton to complete, $2,000; improving Black River, Arkansas and Missouri, maintaining existing works, $5,000; improving White River, continuing improvement, $30,000; improving Fourche River, completing improvement, $7,500; improving Ouachita and Black Rivers, Arkansas and Louisiana, continuing improvement, $15,000.

TENNESSEE.

Improving Big Hatchie River, continuing improvement, $5,000; improving Caney Fork River, continuing improvement, in accordance with last survey, $2,500; improving Clinch River, continuing improvement, $4,000; improving Cumberland River, Tennessee and Kentucky, continuing improvement above Nashville, $250,000: *Provided*, That in the discretion of the Secretary of War $50,000 of this sum may be expended in commencing the improvement of said river at Smith's Shoals. Improving Cumberland River, Tennessee and Kentucky, below Nashville, continuing improvement, $40,000, $30,000 of which to be used in improving the mouth of the river; improving French Broad River, continuing improvement, $10,000; improving Hiawassee River, to complete improvement, $1,500; improving Forked Deer River, continuing improvement, $2,500; to be expended on the North Fork From Dyersburg to the main river, and thence on the main river to its mouth; improving Tennessee River above Chattanooga, continuing improvement, $30,000, of which $15,000, or so much thereof as may be necessary, shall be used in making a careful and comprehensive survey of said river from Chattanooga to the junction of the Holston and French Broad Rivers, with a view of ascertaining to what extent the navigation of the river is capable of improvement, and the cost of the same, and the preparation of suitable plans therefor; improving Tennessee River, below Chattanooga, including Colbert Shoals and Bee Tree Shoals, continuing improvement, $475,000, out of which $25,000 may be used at Livingston Point at the mouth of said river, in accordance with the recommendation of the engineer in charge of that portion of the river.

MISSISSIPPI.

Improving Big Sunflower River, continuing improvement, $5,000, of which $1,500 is to be used between Woodburn and Lehrton; improving Noxubee River, continuing improvement, $3,000: improving Pascagoula River, continuing improvement, $20,000; improving Pearl River, between Edinburgh and Carthage, to complete improvement, $5,000; improving Pearl River, between Carthage and Jackson, continuing improvement, $3,000; improving Pearl River, below Jackson, continuing improvement, $20,000, $5,000 of which shall be used for dredging at the mouth; improving Steele's Bayou, including Washington Bayou, continuing improvement, $2,500; improving Tallahatchie River, continuing improvement, $5,000; improving Tchula Lake, continuing improvement, $3,000; improving Yazoo River, continuing improvement, $25,000, of which $5,000, or so much as may be necessary, shall be used in making a survey of the Yazoo River from the bridge of the Louisville, New Orleans and Texas Railway to its mouth, for the purpose of determining in what manner the mouth of the river can be so improved as to freely permit the passage through the same, at all seasons of the year, of vessels engaged in the navigation of the river; and said survey shall also include an investigation into the feasibility and advantages of making a new mouth or outlet for said river, by way of Chickasaw Bayou, or otherwise, together with an estimate of the cost of the same; improving Bluff Creek, to complete improvement, $1,000; improving Chickasahay River, by the removal of logs, snags, and overhanging trees, from the mouth up to Railroad Bridge, near Shubuta, $5,000; improving Leaf River, from its mouth to the mouth of Bowie Creek, $5,000; improving Big Black River, the sum of $5,000, heretofore appropriated for the improvement of this river, may be expended in the improvement of said river, notwithstanding the proviso contained in the act of 1886 making said appropriation.

Improving harbor at Biloxi, continuing improvement, $9,000.

MINNESOTA.

Improving harbor at Duluth, continuing improvement, $100,000, of which sum $40,000 shall be expended on the harbor basin and new channel east of Rice's Point, and in the preservation and maintenance of the canal and piers at the harbor entrance, and $60,000 shall be expended on the channel west of Rice's Point and from thence along the northern shore of Saint Louis Bay to Grassy Point; improving harbor at Grand Marais, continuing improvement, $22,350; improving harbor at Agate Bay, continuing improvement, $25,000. Improving Red River of the North, continuing improvement, $25,000.

MISSOURI.

Improving harbor at St. Louis, $182,000; improving Mississippi River from the Head of the Passes to the mouth of the Ohio River, including salaries, clerical, office, traveling, and miscellaneous expenses of the Mississippi River Commission, continuing improvement, $3,200,000, which sum shall be expended under the direction of the Secretary of War in accordance with the plans, specifications and recommendations of the Mississippi River Commission, for the general improvement of the river, for the building of levees for surveys, including the survey from the head of the Passes to the head waters of the river, for the work at the harbors at Hickman, Ky., at New Madrid, Mo., at Helena, Ark., at Greenville, Vicksburg and Natchez, Miss., at New Orleans, La., at the head of the Atchafalaya and the mouth of the Red River, and at other localities, in such manner, to such extent, and in such proportion as in their opinion shall best promote the interests of commerce and navigation, provided, that the amount expended from such sum for work at the harbors aforesaid shall not exceed $600,000, and the amount expended at the head of the Atchafalaya and the mouth of Red River for the rectification thereof pursuant to the plan heretofore adopted, including keeping open a navigable channel through the mouth of Red or Old River into the Mississippi River shall not exceed $250,000; improving Gasconade River, continuing improvement, $4,000; improving Little River, from Hornersville to its junction with the Saint Francis River, completing improvement, $3,000; improving Saint Francis River, from Greenville to the Arkansas line, continuing improvement, $10,500; improving the Osage River, $55,000, of which sum $5,000 is to be used for snagging, and $50,000 is to be used in commencing the construction of a lock and dam at or near the mouth of said river; improving Black River, continuing improvement, $7,000; improving Missouri River from its mouth to Sioux City, Iowa, inclusive, embracing office, clerical, traveling and other expenses of the Missouri River Commission, surveys, permanent bench marks and gauges, $800,000, to be expended by the Secretary of War in the systematic improvement of the river from its mouth up according to the plans and specifications of the Missouri River Commission, to be approved by him in reaches to be designated by them, provided, that in the discretion of the Commission such portion of said sum and of all unexpended balances from former appropriations during the last four years for the improvement of the Missouri River below Sioux City, or any part thereof, not exceeding $200 and $3,000, as they may deem proper shall be expended in the protection of harbors and localities on any part of the river within said limits; improving Missouri River between the foot of the Great Falls of the said river in Montana and Sioux City, $300,000, to be expended in the discretion of the Secretary of War, and he is authorized to use so much thereof as may be necessary for the providing of two ice harbors, to be located by him.

CALIFORNIA.

Improving Sacramento and Feather Rivers, continuing improvement, $30,000; improving Napa River, completing improvement, $10,000; improving San Joaquin River, continuing improvement, $75,000, of which sum $23,750, or so much thereof as may be necessary, shall be expended in closing Laird's Slough and Paradise Cut, and $24,000, or so much thereof as may be necessary, shall be expended in dredging, and $27,250, or so much thereof as may be necessary, shall be expended for cutting off Head Reach; improving Petaluma Creek, continuing improvement, $4,000; improvement of Redwood Creek, to complete dredging, $8,000.

Improving harbor at Humboldt, continuing improvement, $80,000; improving harbor at Oakland, continuing improvement, $250,000, one-half of which may, in the discretion of the Secretary of War, be expended in dredging the entrance to the harbor; improving harbor at Wilmington, continuing improvement, $34,000; improving harbor at San Luis Obispo, continuing improvement, $40,000; improving harbor at San Diego, $60,500, of which sum $500 shall be expended for repairs, $8,000 for dredging, and the remainder to commence construction of jetty on Zuninga Shoals. That the Secretary of War is authorized and directed to appoint a board of three engineer officers of the United States Army, whose duty it shall be to examine the Pacific Coast between Points Duma and Capistrano with a view to determining the best location for a deep-water harbor. The said board shall report to the Secretary of War a project for said harbor, with the estimated cost of the same, who shall lay said report before Congress at its next session, with the views of the commission and of the Chief of Engineers of the United States Army thereon; and the sum of $5,000, or so much thereof as may be necessary, is hereby appropriated for the purpose.

OREGON.

Improving canal at the Cascades, continuing improvement, $435,000; improving Upper Columbia, including Snake River, Oregon and Washington, continuing improvement, $20,000; improving the mouth of Columbia River, continuing improvement, $475,000; improving lower Willamette and Columbia Rivers in front and below Portland, continuing improvement, $100,000; improving Willamette River above Portland, $11,000, of which sum $5,000, or so much thereof as may be necessary, may be used, in the discretion of the Secretary of War, for improvement of the river at Clackamas Rapids and Ross Island; improving Coquille River; continuing improvement, $30,000, not exceeding $3,000 of which may, with the approval of the Chief of Engineers, be used for snagging; improving Umpqua River, to complete, $9,000; improving the mouth of Siuslaw River, to commence construction of jetty, $50,000; improving Youngs and Klaskuine Rivers, to complete, $1,600.

Improving entrance to harbor at Coos Bay, continuing improvement, $125,000; improving harbor at Yaquina Bay, continuing improvement, $165,000; improving harbor at Tillamook Bay, completing improvement, $500; improving entrance to harbor at Nehalem Bay, $10,000 for commencement of jetty construction.

WASHINGTON.

Improving Columbia River from the head of Rock Island Rapids to the foot of Priest Rapids, $70,000, of which $10,000, or so much thereof as may be necessary, may be used in the survey of the Columbia River from the international boundary to Rock Island Rapids; improving Chehalis River, continuing improvement, $3,000; improving Cowlitz River, continuing improvement, $8,000; improving Shagit, Stielaquamish, Nootsack, Snohomish and Snowqualme Rivers, continuing improvement, $12,000; the Secretary of War is authorized and directed to appoint a board of three officers of the Corps of Engineers of the United States Army, whose duty it shall be to select and survey the most feasible location, and estimate the expense of construction of a ship canal to connect the waters of Lakes Union, Washington and Samamish with Puget Sound, and the sum of $10,000, or as much thereof as may be necessary, is hereby appropriated for its expenses.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTERREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE.

For works for which proposals are requested see also the "Proposal Columns, pages i-ii-288.

WATER.

For Additional Water Items see Proposal Columns.

KANSAS CITY, MO. — The Kansas City *Times*, of September 25, prints the following: "At the next meeting of the Common Council some action will be taken in reference to the water-works matter. The passage of the amendment, giving to the city the power to issue bonds, has placed the situation in a different light, and the Common Council may now treat with the water-works company. President Cannon, of the Upper House, yesterday expressed himself as being in favor of issuing bonds for the erection of new works. Other members of the Council, however, are not inclined to place themselves on record yet."

WATERTOWN, WIS. — The water-works project at his place has been killed by the people.

STROMSBURG, NEB.—The people of this place defeated the water-works proposed by refusing to appropriate $30,000, the amount necessary.

HUNTINGTON, L I.—The taxpayers of this place have united, and are making a determined effort to have a system of water-works.

GREELEY CENTER, NEB.—The proposed system of water-works for this place will probably be established at once.

MORRISTOWN, TENN.—Plans are now ready for a system of water-works for this place.

OENAVILLE, TEX.—A system of water-works is, it is reported, to be established here at once.

FORT WAYNE, IND. — Additional water mains will be laid here, at a cost of $20,000

LOWELL, MASS.—The sum of $60,000 has been voted for additional pumping machinery for the local water-works.

CONWAY, ARK.—This place has decided on establishing a system of water-works, and operations will commence soon.

TROY, N. Y.—Extensions are to be made to the water-works system at this place.

FLATONIA, TEX.—It is proposed to establish a system of water-works at this place, and the plans of the plant are now being prepared.

MASON, TEX.—A water-works system is to be established here by the proprietors of the projected ice factory.

STANLEY, VA.—The Stanley Land and Furnace Company can furnish particulars regarding a system of water-works projected for this place.

ELIZABETH, PA.—A movement towards establishing a system of water-works has developed at this place.

GREENVILLE, TEX.—Improvements are to be made to the plant of the Greenville Water and Electric Light Company of this place.

NORTHAMPTON, MASS.—Extensions to include 2,000 feet of pipe are to be made to the local water-works plant. Address the Water Commissioners, as above.

FRANKLIN, IND.—Improvements are shortly to be made to the plant of the Franklin Light and Power Company. Address the Secretary, as above.

TOLEDO, IOWA.—The following proposals for the construction of a system of water works at this place were opened September 23: W. G. Sherlock & Co., Kansas City, Mo., $16,734; National Tube Works, Chicago, Ill., hydrants, $2,883; Fairbanks, Morse & Co., St. Paul, Minn., $16,284; G. C. Morgan, Chicago, Ill., $16,548; F. Turner, Nevada, Iowa, $18,344. Plans by Geo. C. Morgan, to whom the contract was awarded.

HUNTINGTON, N. Y.—The question of making an appropriation for a water supply is to be brought before the people of this place October 6.

ELWOOD, IND.—It is proposed to expend the sum of $20,000 on a water-works system for this place.

HAMILTON, MASS.—This place is to have a system of water-works at an early date.

HENDERSON, MINN.—The system of water-works projected for this place will soon be established.

EDDY, TEX.—The people of this place have decided to establish a system of water-works.

SEQUATCHIE, TENN.—A system of water-works is to be established at this place by the Sequatchie Water Co.

HARDWICK, VT.—A complete system of water-works is to be established at this place as soon as the preliminary arrangements can be made.

JOLIET, ILL.—The city has decided to have a public fountain erected, to cost $5,000 or more. Address Charles C. Wilcox, City Clerk, for information. The Water-Works Company will take steps to procure two new boilers.

NASHUA, N. H.—The Pennechuck Water Company have consulted with M. M. Tidd, C. E., of Boston, in the matter of enlarging the water-works of this place by the addition of new pumping machinery, laying new mains, etc.

BRECKINRIDGE, TEX.—It is said that the people of this place favor establishing a system of water-works and that the Mayor can furnish particulars.

HAMILTON, MASS.—The Town Clerk at this place writes: "We have circulated paper for signers for water-works project."

ANTRIM, N. H.—Commissioner S. R. Robinson writes: "George C. Patten, C. E., East Deering, N. H., is making surveys for us but has not yet completed the same. He is drawing plans for bringing water from springs 1¼ miles west of village; reservoir 181 feet higher than Main Street. Cannot tell at present whether the works will be put in or not."

MILFORD, MASS.—Water-Works Superintendent A. A. Jenkins writes: "Voted to put up stand-pipe and a committee appointed for that purpose, to get specifications, etc. Also to put in more pumping capacity if needed when stand-pipe is built. Add to water supply also."

RITZVILLE, WASH.—Town Clerk S. S. Crons writes: "Nothing as yet has been done towards water-works. I do not think there will be anything done for some time yet—probably not this year."

PULLMAN, WASH.—Town Clerk Thomas Neill writes: "Election for $9,000 bonds, 15 years, at 6 per cent., will be held October 21, 1890. A prior election, which was found defective, was unanimous for bonding. The system is the reservoir and steam pump, so as to give either hydraulic or steam power."

ARKADELPHIA, ARK.—City Recorder A. S. B. Green writes: "We have appointed the Finance Committee relative to having water-works at this place, which is open for contractors."

EUSTIS, FLA.—It is probable that immediate steps will be taken towards the construction of a system of water-works at this place.

ISLIP, N Y.—At a recent meeting of the Islip Town Board the Great South Bay Water Company's plant was accepted, the only point of difference to be settled being as to when the town shall commence paying for the use of its fire hydrants.

BABYLON, N. Y.—The question of establishing a system of water-works at this place is to be decided at a special election to be held October 11.

TOLEDO, IOWA.—The following bid for constructing a complete system of water-works were received by Mayor A. M. Beal, September 23: George C. Morgan, Chicago, $16,538. Contract let as per above bid.

LOWELL, MASS.—Our correspondent writes: "The water-works are to have a $60,000 pumping engine, in addition to the two others."

TOPEKA, KAN.—A charter has been filled with the Secretary of State, for the Kansas Water Company, which proposes to build water-works in this city. The company is composed of J. B. Bartholomew, A. B. Quinton and others. The capital stock is $750,000. The ordinance provides that water is to be supplied from the Kansas River, and that the water-works are to be constructed of not less than 3,000,000 capacity, fire pressure, in 24 hours.

GREENVILLE, S. C.—The water-works system proposed for this place is now a certainty.

ADAIRSVILLE, GA.—Town Clerk G. B. Casny writes: "The water-works matter is under consideration, in fact a committee has been appointed to devise or say what style, etc."

CINCINNATI, O.—John W. Hill, Consulting Engineer, writes: "Plans for Eaton, O., water-works now under way, and when ready will be glad to give you a synopsis of the work."

PASADENA, CAL.—The Pasadena Land and Water Company intends to lay about a mile of 12-inch water pipe, maximum pressure about 7 feet. They may use salt-glazed vitrified clay pipe.

TACOMA, WASH.—The *Pacific Lumberman*, of San Francisco, prints the following: "The preliminary surveys for the new gravity supply from the Green River are nearly completed. The intention is to take water from the river at a point about 32 miles from the city, starting with an elevation sufficient to carry the water 500 feet above the tide in Tacoma. A new 25,000,000 gallon reservoir has been proposed for the middle service, and a 9x125-foot iron stand-pipe now under construction will supply the high service. The old reservoir will supply the low service. The estimated cost of the various improvements is $1,400,000. Charles P. Darrach, of Philadelphia, is engineer for the new works."

ALLEGHENY, PA.—The following proposals for a new pumping station, reservoir, filters and $8\frac{74}{100}$ miles of 60-inch water conduit, were opened by the Water Committee, October 1. Filtering system: National Pumping Co., $240,000; American Filtering Co., $260,000; Hyatt Filter Co., $369,429.60; Holly Manufacturing Co., $165,000; E. P. Alles & Co., for pumping station, $145,000, and for boilers, $30,000. The other bids were for $8\frac{74}{100}$ miles of 60-inch water main: T. P. Gillespie, $22.25 per foot, or $1,026,770.75 for the whole if steel, and $996,775.25 if iron; Fred Gwinner, for conduit, $1,010,000; for reservoir, $1,059,900; for buildings and engines, $724,000; whole plant, $2,825,000, excepting filters: Porter Manufacturing Co. for conduit, $845,000, and $2.50 per yard for all rock excavated; Oliver Iron and Steel Co., for conduit, $911,849; Butts & Kauffman, for pumping station, $565,000; Harold & McDonald, pumping station, excepting iron, steel and brickwork, $299,900; for battery of boilers of 1,500 horse-power, Carroll-Porter Boiler Co., $30,000; Abendroth & Root Company, $32,000; Sterling Co., $26,375 and $19,125; J. B. Sheriff Sons & Co., $32,784; Porter Boiler Manufacturing Co., $28,975; John Elgell, Jr., $25,500 and $24,700; Campbell & Zell Co., $31,570; for six stop-gate valves, Rensselaer Manufacturing Co., $1,950 each; Ludlow Valve Manufacturing Co., $1,845 each; Specialty Manufacturing Co., $960 each; T. F. Keating, $11,400 for all; R. D. Wood & Co., $1,300; Eddy Valve Co., $2,625 each; Coffin Valve Co., $18,000 for all. The Municipal Water Co. made two bids on the building and filter, one for $347,000, which called for a very imposing structure, and another for $280,000. A sub-committee has been appointed to tabulate each bid before the contract will be awarded.

CENTRALIA, WASH.—J. A. Miller, who is interested in the water-works franchise, reports that the engineers have almost completed surveys, and that work will be begun at an early day. The water will be brought from the Newaukum River and stored on Seminary Hill in a 5,000,000 gallon reservoir, 230 feet above the level of the Northern Pacific Railroad.

MANCHESTER, N. H.—An official of this place writes as follows: "We are making surveys for a high service and have not decided on anything yet, and of course are not sure that any will be built, on account of cost of same. It all will depend on surveys."

JACKSONVILLE, FLA.—Riverside, a suburb of this place, is to have a system of water-works, to be established by the Riverside Artesian Well Co. Address S. E. Foster, Secretary, as above.

COLDWATER, MICH.—The following proposals for the construction of water-works at this place were opened September 16, by J. D. Cook, Consulting Engineer:

Pipe and specials: Dennis Long, Louisville, Ky., $35,415.80; Detroit Pipe Foundry, Detroit, Mich., $35,353.15; Lake Shore Foundry, $34,688.76; Addyston Pipe and Steel Co., $35,593.30; Jackson & Woodin, $39,490.68.

Pipe laying: Walson & Moran, $13,111.50, $4.50 each for boxes; W. H. Longham & Co., $10,824.85; Snyder & Williams, $10,753.57; T. C. Crooks, $12,198.20; Dogiach Construction Co., $14,445.50; R. B. Caruthers, $12,859 50; J. W. McLane & Co., $13,226.87; A. H. Phillips, $12,093.80; Moffitt, Hodgkins & Co., $15,863.90.

Complete plant: Moffett, Hogdkins & Clark, Syracuse, N. Y., $82,065; Geo. C. Morgan, $68,047.

The remainder of the figures on the plant will be published next week.

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Troy, N. Y.; Dallas City, Ore.; New York City; Ellsworth, Kan.; Vancouver, Wash.; St. Louis, Mo.; Austin, Tex.; Berryville, Va.; Toronto, Can.; Rushville, Ind.; Ashland, Ky.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

WILLIAMSPORT, PA.—The local officials have adopted plans for a system of sewers.

COLUMBUS, GA.—Immediate operations are expected on the proposed system of sewers for this place.

WHEELING, W. VA.—The local sewerage system is to be improved.

SCRANTON, PA.—It is proposed to make an expenditure of $75,000 on improving the sewerage system at this place.

STUTTGART, ARK.—The sewerage system, which has been spoken of for this place for several months, is about to be established by the Stuttgart Improvement Company.

HOBOKEN, N. J. — Plans have been completed for a system of sewers for this place, which is to cost $250,000.

ROCHESTER, N. Y.—Numerous sewer extensions are to be made at this place.

OMAHA, NEB.—Additional sewers are to be established at this place.

AKRON, O.—An exchange prints the following: "State Engineer John Myers and Samuel Bachtell, have been in Summit County looking over the ground in the vicinity of Wolf Creek lock in Norton Township, with a view to the drainage of the Pigeon Creek and Wolf Creek flats. The investigation of Messrs. Myers and Bachtell resulted in their determination to begin this fall the construction of an aqueduct for Wolf Creek under the canal, and to apply the $4,000 already appropriated for that purpose, on condition that $6,000 additional should be made up by parties immediately interested. This latter sum has already been pledged, and the work will go forward at once. The plan proposes dredging Tuscarawas River for a distance of seven miles below the junction of the canal with Wolf Creek."

DENNISON, O.—The City Council wants estimates for the sewerage and paving of certain streets.

PAWTUCKET, R. I.—Improvements are to be made to the sewerage system of this place. A R Sweet can furnish particulars.

CINCINNATI, O.—The Board of Public Improvements has ordered the construction of numerous sewer extensions.

East Portland, Ore.—Messrs. Hamand & Kelly, of this city, are preparing plans for a sewerage system for the city of Eugene, Ore.

Peoria, Ill.—King & Dickerson, sanitary engineers and contractors, of this place, have the contract for the construction of a sewerage system at Cedar Rapids, Iowa, and W. A. Dickerson has just left for the latter city to superintend the work.

Red Oak, Iowa.—The taxpayers of this place have decided to undertake the building of a sewerage system at once.

Jamestown, N. Y.—By vote September 26, the taxpayers of this city decided to issue bonds in the sum of $90,000 for a system of sewers.

Brooklyn, N. Y.—The estimated cost of the new sewers ordered October 1, by Commissioner Adams, to be constructed under the Eighth Ward Improvement Act, is placed at $60,000.

Columbus, Ga.—Mayor D. P. Dozier writes: "The city has had prepared plans, maps, etc., for a thorough system of sanitary sewerage, to cost about $100,000. This sewerage, no doubt, will be commenced during this fall or winter and finished as soon as it will be possible to do it. Bids will be advertised for later."

Victoria, B. C.—This place has, by a popular vote, decided to have sewers.

Sewers.—See our Proposal Columns for information regarding sewer work at the following places: Detroit, Mich ; Dubuque, Iowa; Toronto, Can.; Chicago, Ill.; Dayton, Ohio.; Westchester, N. Y.; Denver, Col.; Albuquerque, N. M.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns

Midlothian, Tex.—It is proposed to erect a bridge over Soap Creek, near this place.

Round Timber, Tex.—An iron bridge is to be placed over Spring Creek, in Bayler County.

Hardeman County, Tex.—A bridge is to cross the Red River, connecting Hardeman and Greer Counties.

Norfolk, Va.—Reports say that a bridge to cost $35,000 is to be erected over Smith's Creek, at this place.

Zanesville, O.—The plans for a high bridge over the Muskingum River at Fifth Street, Zanesville, O., have been approved by the U. S. Engineers.

Chicago, Ill.—The city has let a contract for the superstructure of the Weed Street bridge, over the North Branch Canal, to the King Iron and Bridge Manufacturing Company, of Cleveland, for $15,500. The other bids were: Kimbell & Cobb Stone Company, of Chicago, $17,250; and Shailer & Schnighan, Chicago, $26,000.

Also the city has let a contract for the Ninety-fifth Street bridge superstructure over the Calumet River, to the Chicago Forge and Bolt Company, for $11,050. The other bids were: Milwaukee Bridge and Iron Company, $11,300; A Gottlieb & Co., of Chicago, $11,625; Bender & Seifert, of Chicago, $13,250; King Bridge and Iron Manufacturing Company, Cleveland, $15,300; Chicago Bridge and Iron Company, $16,500.

Also a contract for a viaduct for the Canal Street bridge to A Gottlieb, for $11,989. The other bids being: Bender & Seifert, Chicago, $13,000; Chicago Forge and Bolt Company, $13 380; King Iron and Bridge Manufacturing Company, $14,645; Chicago Bridge and Iron Company, $14,949; Milwaukee Bridge and Iron Company, $19,850.

Also a contract for a plate-girder viaduct at Washington Street (the superstructure to be the present Madison Street bridge, revamped), to the King Iron and Bridge Manufacturing Company, of Cleveland, for $16,685; the competitors being the Chicago Bridge and Iron Company, $18,400; A, Gottlieb & Co., $18,563; Kiter & Conley, Pittsburg, $18,760; and the Chicago Forge and Bolt Company, $20,685.

Bayonne, N. J.—The Central Railroad of New Jersey will ereet two new bridges.

Lockport, Ill.—The contract for the construction of the iron work of a bridge at this point will be awarded October 6. Contract for the masonry has just been awarded to R. C. Morrison for $6,000. The estimated cost of the entire structure is about $20,000. N. Whitley, civil engineer, of Joliet, Ill., has the plans.

Columbus, O.—It is reported that the City Engineer will prepare plans for a railway bridge at High Street.

Clifton Forge, Va.—A bridge will be built over Smith Creek, at this place.

Jefferson County, W. Va.—A new bridge is to be constructed over the Opepuan River, connecting Jefferson and Berkley Counties.

Dayton, Tenn.—Reports say that bids will soon be wanted for the construction of two iron bridges at this place.

Augusta, Ga.—Beaver Dam Creek, at this place, is to be bridged.

Baltimore, Md.—The plans and specifications for the Monroe Street bridge are being drawn, and as soon as they are completed proposals for the construction will be advertised for. Mayor Davidson can furnish particulars.

Charleston, W. Va.—Reports say that a bridge is to be erected over the Elk Two-Mile River, at this place.

Dayton, N. C.—Two new iron bridges are to be erected at this place. Address W. Engee, for particulars.

Atchison, Kan.—The following bids for the construction of two iron span bridges were received by W. S. Purcell, Chairman County Commissioners, September 16: King Iron Bridge Co., Weston, Mo., bridge No. 1, Engineer's estimate, $1,515; let for $1,220; Kansas City Bridge Co., Kansas City, Mo., bridge No. 2, $1,198; let for $922.

West Bay City, Mich.—The plans for a bridge across Saginaw River in the first ward are now being drawn, and the building of it is an assured fact. The estimated cost of the bridge is $41,000.

Lincoln, Neb.—Two new bridges are to be erected in this city.

Bridges.—See our Proposal Columns for information regarding bridge work at the following places: Lafayette, Ga.; Spring Valley, Ill.; Greenville, S. C.; Helena, Mont.; Dublin, Ga.; Houston, Tex.; Philadelphia, Pa.

GAS AND ELECTRIC LIGHTING.

Lykens, Pa.—The Williams Valley Light, Heat and Power Co. has been incorporated here, with a capital stock of $40,000. Directors: A. F. Engelbert, F. M. Williams, J. I. DeLancy, and others.

Weldon, N. C.—The people of this place are taking steps towards having an electric light plant.

Frackville, Pa.—The Frackville and Gilberton Light, Heat and Power Co. has been incorporated here, with a capital of $40,000.

Polk Rapids, Iowa.—The Northwestern Gas Light and Heating Co. has been incorporated, and will establish a plant at this place.

Stanley, Va.—An electric lighting plant is to be established at this place.

Reidsville, N. C.—This city is about to purchase the plant of the Danville Electric Light Co., and it is probable that after the transfer improvements will be made.

Fredonia, N. Y.—All the bids received for putting in an electric light plant at this place have been rejected, as excessive, and another set of plans and specifications will be prepared, after which new proposals will be wanted.

Montreal, Canada.—There is some talk of establishing a new gas company at this place.

Jamestown, N. Y.—The taxpayers of this place have voted the sum of $30,000 for the purpose of establishing an electric lighting plant.

Modesto, Cal.—The City Trustees have granted a franchise for an electric plant for Modesto to A. C. Swain, of Merced.

Electric Railways.—New electric railways will be constructed, and improvements will be made to those already established at the following places: Kinkora, N. J.; Washington, Pa.; Burlington, N. J.; Glens Falls, N. Y.; Madison, Wis.; Chicago, Ill.; Los Angeles, Cal.; South Manchester, Conn.; Allegheny, Pa.; Duluth, Minn.; Bridgeport, Conn.; Houston, Tex.; Salt Lake City, Utah; Fargo, Dak.

Seattle, Wash.—The City Clerk has been ordered to advertise for street lights, those of intensity of 16 candle-power, 30 candle-power, and arc lights of 2,000 candle-power.

STREET-WORK AND PAVING.

St. Paul, Minn.—Plans and specifications will soon be prepared by the City Engineer for the improvement of five miles of streets.

Marion, N. C.—The sum of $10,000 is to be expended in improving the public streets of this place.

Oakland, Cal.—Many of the streets of this city are to undergo extensive improvements.

Kansas City, Mo.—It is proposed to expend the sum of $100,000 on street improvements for this place.

BIDS OPENED.

St. Paul, Minn.—The court-house and city hall commission have awarded contracts for storm sash and doors for the new building to J. H. Donohue for $3.475. Other bids were: Corlies, Chapman & Drake, $6,400; Lenn, Fawcett & Johnson, $4.199.52; Bohn Manufacturing Company, $6.495; William Lettan, $5,577.

GOVERNMENT WORK.

Washington, D. C.—D. J. Curtis, of Springfield, Mass., has been awarded the contract for the construction of the Troy (N. Y.) public building, at his bid of $32,200.

Port Townsend, Wash.—The following proposals for iron columns, iron and wood floor and roof construction, terra cotta arches, etc., for the custom house, post office, etc., at this place, were opened September 30, by the Supervising Architect of the Treasury Department: Clark, Raffen & Co., Chicago, Ill.; $39,340; John Field, Omaha, Neb., $43,850, F. J. Myers Manufacturing Co., Covington Ky., $50,500.

Nashville, Tenn.—The following bids for the part construction and completion of Lock No. 1, Cumberland River, near this city, were opened by J. W. Barlow, Lieutenant-Colonel of Engineers, U. S. A., Sepsember 23: Henry F. Holmes, Nashville, Tenn., $35,490.50; L. M. Petitdidier, Cincinnati, O., $43,204.

Washington, D. C.—Bids were opened at the Navy Department, October 1, for building three armored battle ships of 9,000 tons displacement, and one protected cruiser of 7,500 tons displacement. The first bid was that of the Union Iron Works, of San Francisco, who offered to build one battle ship on the Department's plan for $3,420,000, or two for $3,200 000 each, making a total of $6,400,000. Cramp & Son, of Philadelphia, bid 2,990,000 for one battle ship on the Department plan, or $3,120,000 on their own plan, and for two on the Department plan at $2,890,000 each. They also bid $3,020,000 each for the ships on their own plans. The Bath Iron Company made one bid, that for the battle ship on the Department plan, for $3,149,000. The Risdon Iron Works, of San Francisco, also bid for the battle ship on the Department's plan, their proposal being $3,275,000. The next bid was for protected cruiser No. 12. The Union Iron Works bid $3,025,000, and Cramp & Son $2,725,000, both on the Department plans. The Bath and Risdon companies did not bid on the cruisers.

INDUSTRIAL.

Long Branch, N. J.—Percy Dobbins submitted the plans and profile of the proposed improvements to Ocean Avenue to the Long Branch Commissioners at their last meeting. Mr. Dobbin's project contemplates the erection of jetties from 50 to 100 feet seaward, 300 feet apart, and bulkheads of 4-inch planking driven slanting as deep as they can be forced The bulkheads and jetties will extend from Elberon to North Long Branch. The Commissioners gave their assent to the adoption of the plans, and he will proceed with the work as soon as the contracts can be completed and the specifications filed. The Commissioners propose to macadamize or asphalt the Ocean Avenue drive, and to put down flagging or other acceptable material on the 4-foot wide promenade on the bluff.

Duluth, Minn.—At a meeting of the City Council, held September 29, a resolution was adopted instructing the Board of Public Works to correspond with tunnel engineers with the aim of getting at the cost, length of time required and feasibility of placing a tunnel under the ship canal across Minnesota Point.

PROPOSALS.

(Continued from page ii.)

TO CONTRACTORS.

Department of Public Works,
Bureau of Surveys,
Philadelphia, September, 30, 1890.

PROPOSALS FOR CONSTRUCTING wrought-iron approaches to Walnut Street **BRIDGE**, and for bituminous concrete, will be received by LOUIS WAGNER, Director of the Department of Public Works, at this office, until 12 o'clock noon, MONDAY, October 27, 1890.

Proposals must be accompanied by a certificate that a bond for $500 has been filed in the Department of Law, Sixth and Locust Streets.

Blue prints copies of the plans on exhibition here may be obtained by those first applying upon payment of five dollars to the Receiver of Taxes.

J. MILTON TITLOW,
Principal Assistant Engineer.

Notice to Contractors.

SEALED BIDS FOR THE **GRADING, SEWERING, DRAINING, MACADAMIZING**, and otherwise improving the streets and avenues of PELHAM HEIGHTS, WESTCHESTER CO., N. Y., in accordance with the contract and specifications to be furnished by the Engineer in charge, No. 152 Prospect Avenue, Mt. Vernon, N. Y., until 12 o'clock M. of WEDNESDAY, October 15, 1890.

No bids will be received unless accompanied by a certified check for five hundred dollars as a guarantee of signing contract if bid is accepted.

All bids must be made upon the blank forms furnished by the engineer.

The owners reserve the right to reject any or all bids or parts of bids. Bids must be made for the whole work.

The sewers are to be pipe sewers. The property is situated at Pelhamville Station, N. Y., N. H. & H. R. R.

The following is a general summary of the estimates:

Grading	81,399	cubic yards.
Macadamizing	78,615	square yards.
Gutters	49,930	lineal feet.
Sidewalks	27,693	square yards.
Sodding	35,903	" "
Trees to be planted	1,645	
Sewerage	30,318	lin. ft. of pipe with accessories.
Drainage	13,000	" " "
Water pipe	30,986	" " "
Gas pipe	30,000	" " "

Plans can be seen, and specifications and other printed forms obtained upon application to the Engineer in charge.

BEN. L. FAIRCHILD,
GEORGE B. CRUMBIE, } Owners.

John F. Fairchild,
Engineer in Charge. 18

AQUEDUCT, New York City.—Proposals are wanted until October 8, for building 11 head-house superstructures, etc., for the shafts of the new Croton Aqueduct. Address John C. Sheehan, Secretary of the Aqueduct Commission, as above.

PUMPING ENGINES, Toronto, Can.—Proposals are wanted until October 20, for furnishing two duplex pumping engines, with a 10,000,000-gallon capacity, also the necessary boilers, etc., for the same. Address William J. Hill, Chairman Committee on Water-Works, as above.

DREDGING, New York City.—Proposals are wanted until October 13, for dredging for proposed bulkhead wall at East One Hundred and Second Street section on the Harlem River. Address the Department of Docks, Pier A, North River, as above.

STATE CANALS, Albany, N. Y.—Proposals are wanted until October 6, for doing certain work on the State canals. Address Edward Hannan, Superintendent of Public Works, as above.

187 buildings costing less than $7,000.

COLUMBUS, O.—12 dwells; cost, $25,000.

DETROIT, MICH.—Jefferson av, bet St Aubin av and Dubois st, 2-story br and s res; cost, $13,000; o, M Marts; a, Gordon W Lloyd; b, individual contracts.

4th st, bet Plum and Cherry sts, 2-story br double res; cost, $8,000; o and b, Robt Bed; a, Harry J Rill.

Ferry av, bet Chene st and Grandy av, 6 2-story fr res; cost, $9,000; o, R White; b, individual contracts.

Kirby and Grandy avs and Chene st, 6 2-story fr res; cost, $9,000; o, R M Bahan; b, as above.

GALVESTON, TEX.—Ave H and 20th st, electric light station for Galveston Electric Street Car Railway; cost, $20,000; o, William H Sinclair; a, N J Clayton & Co.

HARVEY, ILL.—Church and school; cost, $13,000; a, Flanders Zimmermann.

Hotel; cost, $16,000; o, C G French; a, Sprague & Newell.

LEWISTON, ME.—Chestnut st, 4-story fr block; o, Geo A Wiseman; a, Coburn & Sons.

LOWELL, MASS.—Westford st, fr store and ten bldg; cost, $15,000; o, C I Hood; b, not let.

The Massachusetts Corporation is to build an addition to one of its mills.

Plans have been submitted for a new depot at the Middlesex st station by the Boston and Maine R R Co.

READERS of **THE ENGINEERING AND BUILDING RECORD** interested in the Contracting News Department of that paper are respectfully requested to examine those columns every week, and advise the Editor of any item which they may find that, in their judgment, is of no value to any one other than the person mentioned.

BUILDING INTELLIGENCE.

MANAYUNK, PA.—Cor Main and Robinson, 5-story br store bldg; cost, $16,000; o, A & P Roberts; a, L S Jacoby; b, not yet contracted for.

MERIDEN, CONN.—Liberty st, 4 2-story tenement houses; cost, $18,000; o, C N Cahill; a, D Bloomfield; b, not let.

Main st, residence; cost, $10,000; o, I Lewis; a, H M Jones; b, not let.

MILWAUKEE, WIS. — Cor Martin and Marshall, residence, cost, $20,000; o, Ed R Bacon; a, Ferry & Close; b, Val Maudt.

Grove nr Walker st, store; cost, $15,000; o, J Katz; a, H P Schmetzky; b, W Zeimann.

NORTH WALES, PA.—A college building is to be erected here, to cost $50,000.

NEWARK, N. J.—Architects Schweitzer & Deimer have made plans for a 3-story brick building, to be erected at 54 15th av, to cost about $12,000; Jeremiah O'Rourke has made plans for a row of brick dwellings; the same architect has made plans for a 3-story brick store and dwelling.

ORANGEBURG, S. C.—The Knights of Honor and Edisto Rifles are soon to erect a lodge room and armory, at a cost of $10,000. For further particulars, address L H Wannamaker, as above.

PHILADELPHIA, PA.—S s Paschal st, nr 48th st, 8 dwells; o, W S P Shields.

E s 15th st, n Dauphin st, storehouse; o, C C Haines.

Kip and Kambria sts, 8 dwells; o, Thos McFarland.

N w cor 18th st and Penn av, factory; o, J M Charest.

S s Washington av, w 20th st, factory; o, Phospher Bronze Smelting Co.

E s Woodland av, n 73d st, dwell; o, J Welsh.

52d st, w of Media st, machine shop; o, Chambers Bros.

S w cor 11th st and Colon av, depot; o, S Hart & Son.

E s 12th st, w of Cambria st, hotel; o, W W Binder & Son.

S e cor 25th st and Sederlby av, office; o, W C Merritt.

N s Manheim st, e Wissahicokon av, club house; o, Brennfuger & Ploucher.

9th and Somerset sts, 22 dwells; o, J M Sharp.

PORT DOVER, ONT.—4-story br hotel; cost, $50,000; o, Syndicate, (Thos Hyland, Detroit, Agent); a, W P Clarke, Detroit; b, not let.

READING, PA.—11th and Windsor, stone church; cost, $12,000; o, Reformed Congregation; a, Mr Fry; b, J Angstadt.

Benjamin and 4th, br church with stone trimmings; cost, $10,000; o, Reformed Congregation, Rev McCauley, Pastor; a, Mr. Mull.

Greenwich and 5th, Queen Anne cottage; cost, $7,500; o, J Mishler; a, Smith Bros; b, J Koch.

ROCHESTER, N. Y.—Harper st, 4 fr and cut stone bldg; cost, $4,500 each; o, Wheeler & Wilson; a, H B Gleason.

Harber st, fr bldg; cost, $3,500; o, I Miller: a, same as above.

Edgewood Park, fr and cut stone bldg; cost, $3,000; o, T Chamberlain; a, same as above.

Thayer st, fr bldg; cost, $3,000; o, Wm Oviatt; a, same as above.

SNOW HILL, MD.—A hotel, to cost $20,000, is to be erected at this place.

SALT LAKE CITY, UTAH.—Main st cor 3d st, S, 3-story br store, cost, $60,000; o, Walker Bros; a, Carroll & Kern.

ST. PAUL, MINN.—7th nr Robert, iron, brick and glass arcade; cost, $50,000; o, W P Murray.

The St. Paul Building and Improvement Company have filed plans for a 3-story brick block on Arkwright and Case sts. The structure will cost $50,000.

BUILDING INTELLIGENCE.

ST. LOUIS, MO.—10th and Victor sts, br stable; cost, $9,000, o, St Louis Brewing Co; b, C Weking.

Cote Brilliante and Grand avs, br dwell; cost, $8,000; o, Mrs C Laumann, b, Goesse & Remmers.

Lucas and Grand avs, br dwell; cost, $13,200; o, R H Stockton; b, J H Bowler.

N e cor Kings Highway and Pac R R, br planing mill; cost, $10,000; o, Lohse Pat Door Co; b, sub let.

Manchester Rd and Papin av, br warehouse; cost, $10,000; o, H Bischoff; b, sub let.

TAMPA, FLA.—A court-house, to cost $75,000, is to be erected at this place.

WALTHAM, MASS.—River st, fr box factory; cost, $8,000; o, Boston Manufacturing Company.

Cor Prospect and Russell sts, 2-½story double fr dwell; cost, $10,000; o, Elijah Anderson; b, L W Martin.

WYANDOTTE, MICH.— 3-story br 'bus and lodge bldg; cost, $7,000; o, A O of U W; a, Malcomson & Higginbotham, Detroit; b, not let.

YORK, PA.—Cor Geo and Market sts, s br and iron hotel, 7 stories high; cost, $90,000; o, York Hotel Co; a, J A Dempwolf; b, Menough & Slagle.

THE CONTRACTING NEWS DEPARTMENT of **THE ENGINEERING AND BUILDING RECORD** is edited with a view of giving space to no item that does not indicate where professional services or supplies may be needed in the near future, the prices bid for work or supplies, and the correction of false or misleading reports in some papers, that may subject readers to needless trouble and expense in going after something that does not exist.

DENVER, COL.—S 15th, bet 14th av and Colfax, br dwell; cost, $9,000; o, P V Carlin; a, Gwdovant Bros.

California, Cor 22d st, br terrace; cost, $27,000; o, Lenoard & Motgomery; a, Barresen Bros.

Broadway, bet 17th and 18th avs, interior hotel finish; cost, $125,000; o, Bush & Morse; a, L M Wood.

Corona, bet 19th av and Colfax, 2 br dwells; cost, $8,000; o, G W Huntington.

Curtis st, bet 12th and 13th sts, br store; cost, $7,000; o, J H Montgomery; a, M Merideth.

Market st, bet 38th and 40th st, br hotel; cost, $20,000; o, B M Williams; a, W T Nelson.

28th st, bet Calif and Stout sts, double br dwell; cost, $8,000; o, W R Carr; a, Alex Cuzin.

MINNEAPOLIS, MINN.—7th av, s e 2d st, br machine shop and foundry; cost, $45,000; o, Herzog Mfg Co; a, F J Llwelyn.

324–28 N 1st, br warehouse; cost, $35,000; o, Wood & Moses: a, W C Whitney; a, Haglin & Morse.

4113–17 18th av, S, fr ten; cost, $9,500; o, S Ahlman.

3d av, N, bet 2d st and Washington av, add to Power House; cost, $10,000; o, Minneapolis Street Ry Co; a, C Wise; b, I M Libbey.

BUILDINGS.—There is nothing over $7,000 in value to report at the following places: Pottstown, Pa.; Pottsville, Pa.; Harrisburg, Pa.; Montclair, N. J.; Geneva, N. Y.; Zanesville, O.; Charleston, S. C.; Chester, Pa.; Worcester, Mass.; Minneapolis, Minn.; Poughkeepsie, N. Y.; Pasadena, Cal.; Fitchburg, Mass.; Wheeling, W. Va.; San Antonia, Tex.; Wilkes Barre, Pa.; Dennison, O.; Clinton, Iowa; Springfield, O.; Canton, O.; Dayton, O.· Topeka, Kan.; Findlay, O.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

NOW APPEARING IN THE ENGINEERING AND BUILDING RECORD.

I.—Introduction. Issue of November 27, 1886.

II., III., IV.—Erection of the Towers of St. Patrick's Cathedral in New York City. Seven Illustrations. Issues of December 4, 11, and 18, 1886.

V —Improvements in Dredging Machinery. Thirteen Illustrations. Issue of December 25, 1886.

VI.—Dumping-Scows. Thirteen Illustrations. Issue of January 1, 1887.

VII., VIII., IX., X., XI.—The Equitable Building in New York City. Thirteen Illustrations. Issues of January 8, 22, 29, February 5 and 12, 1887.

XII.—Carson's Trench Machine. Four Illustrations. Issue of February 19, 1887.

XIII.—Raising the Old Court-House in Boston. Three Illustrations. Issue of March 5, 1887.

XIV.—Cram's Steam Pile-Hammer. Five Illustrations. Issue of March 12, 1887.

XV.—The Equitable Building, New York City. Three Illustrations. Special Hoisting Engine and Derrick. Issue of March 26, 1887.

XVI.—The Equitable Building, New York City. One Illustration. Shoring of Column. Issue of April 9, 1887.

XVII.—Bridge-Erecting and Hoisting-Engine used on the Suburban Elevated Railway, New York City. Three Illustrations. Issue of April 30, 1887.

XVIII.—Traveler for Erecting Columns and Transverse Girders, Kings County Elevated Railway, Brooklyn, N. Y. Four Illustrations. Issue of June 4, 1887.

XIX.—Excavating Apparatus used on the Tancarville Canal and Sewer, Havre, France. Three Illustrations. Issue of July 2, 1887.

XX.—Tipple Cars on the New Croton Aqueduct. Six Illustrations. Issue of August 13, 1887.

XXI.—Derrick, Foot Block and Sheaves at Shaft 14 on the New Croton Aqueduct. Two Illustrations. Issue of September, 17, 1887.

XXII.—The Potomac Flats Dredging Plant. Nine Illustrations. Issue of October 8, 1887.

XXIII.—The Tube-Riveting Machines at the Forth Bridge. Two Illustrations. Issue of October 22, 1887.

XXIV.—The Lockwood Dredge. Cape Cod Ship Canal. Eight Illustrations. Issue of November 5, 1887.

XXV.—Location of Plant at Shafts on the New Croton Aqueduct. Two Illustrations. Issue of November 12, 1887.

XXVI.—Material Lock used in the Pneumatic Caissons at the Forth Bridge. Illustrated. Issue of December 3, 1887.

XXVII.—Six-Ton Universal Traveling Crane for Elevated Railroad Erection. Illustrated. Issue of December 17, 1887.

XXVIII.—Head-House on the New Croton Aqueduct at Shaft 22. Illustrated. Issue of December 24, 1887.

XXIX.—The New Harlem River Bridge. Illustrated. Issue of January 21, 1888.

XXX.—Erection of Poughkeepsie Bridge, No. I. Illustrated. Issue of March 3, 1888.

XXXI.—Oil Rivet Furnace at the Forth Bridge Works. Illustrated. Issue of April 21, 1888.

XXXII.—Erection of Poughkeepsie Bridge. No. 2. Masonry. Illustrated. Issue of May 5, 1888.

XXXIII.—Erection of Poughkeepsie Bridge. No. 3. False Work. Illustrated. Issue of May 12, 1888.

XXXIV.—Erection of Poughkeepsie Bridge. No. 4. Travelers. Illustrated. Issue of May 19, 1888.

XXXV.—Erection of Poughkeepsie Bridge. No. 5. Riveting Traveler, Derrick, and General Plant. Illustrated. Issue of May 26, 1888.

XXXVI.—Erecting Traveler on Kettle Creek Trestle. Illustrated. Issue of June 2, 1888.

XXXVII.—Erection of Central Viaduct, Draw Span, Cleveland, O. Illustrated. Issue of June 9, 1888.

XXXVIII.—The 70-foot Caissons at the Forth Bridge. Illustrated. Issue of June 9, 1888.

XXXIX.—Raising an Engine at Poughkeepsie Bridge erection. Illustrated. Issue of June 16, 1888.

XL.—The Hydraulic Spade at the Forth Bridge Works. Illustrated. Issue of June 30, 1888

XLI.-XLVI.—Harlem River Bridge Erection. No. 2. Masonry. Illustrated. Issue of July 7, 1888.—No. 3. Cement and Concrete. Illustrated. Issue of July 14, 1888.—No. 4. Hoisting Apparatus; Revolving Derrick. Illustrated. Issue of July 21, 1888.—No. 5. Hoisting Apparatus; Floor Travelers. Illustrated. Issue of July 28, 1888.—No. 6. Derrick Details and Shipping. Illustrated. Issue of August 11, 1888.—No. 7. Support of Segments, Field Riveting, etc. Illustrated. Issue of September 1, 1888.

XLVII.—Head-House on New Croton Aqueduct at Shafts Nos. 1. 2. Illustrated. Issue of September 8, 1888.

XLVIII.—Lever Truck for Handling Bridge Material. Illustrated. Issue of September 15, 1888.

XLIX.—Bismarck Bridge. Erecting Traveler. Illustrated. Issue of November 3, 1888.

L.—Details of Head House, New Croton Aqueduct. Illustrated. Issue of November 17, 1888.

LI —Suspended Tipple for Dumping Cars on the New Croton Aqueduct, N. Y. Illustrated. Issue of December 15, 1888.

LII.—A Viaduct Erecting Traveler. Illustrated. Issue of December 22, 1888.

LIII.—Ropes and Tackle. Illustrated. Issue of December 29, 1888.

LIV.—Power used for Operating Plant on the New Croton Aqueduct. Issue of January 19, 1889.

LV.—Special Methods of Handling Material on the New Croton Aqueduct. Issue of February 16, 1889.

LVI. Railway Bridge Erection in Peru. Part I. The Erection of a 200-foot Span. Illustrated. Issue of February 23, 1889.

LVII.—Railroad Bridge Erection in Peru. Illustrated Issue of March 2, 1889.

LVIII.—Erection of Omaha Bridge. Part I. General Description and Erecting Travelers. Issue of March 9, 1889.

LIX.—Erection of Omaha Bridge. No. II False Work in Channel Span. Illustrated. Issue of March 16, 1889.

LX.—Building the Centre Pier of Railway Drawbridge. Illustrated. Issue of March 23, 1889.

LXI.—The Sugar River Bridge Erection. False Work. Illustrated. Issue of March 30, 1889.

LXII.—Erection of Canadian Pacific Railway Depot, Montreal, P. Q. Illustrated. Issue of April 20, 1889.

LXIII.—Erection of a Plate Girder Bridge. Illustrated Issue of May 18, 1889.

LXIV.-LXV.—The Boylston Street Bridge, Boston, Mass. Illustrated. Issue of June 8 and 22, 1889.

LXVI.—Erection of Harvard Bridge, Boston, Mass. Illustrated. Issue of June 29, 1889.

LXVII.—False Work of St. Peter's Bridge over the Dadore. Illustrated. Issue of August 10, 1889.

LXVIII.—Methods of Timbering Shafts on the New Croton Aqueduct. Illustrated. Issue of August 17, 1889.

LXIX.—The Erection of Machinery Hall at Paris Exposition. Illustrated. Issue of August 24, 1889

LXX.—Hoisting Cages on the New Croton Aqueduct Illustrated. Issue of August 31, 1889.

LXXI.-LXXIII.—Erection of Machinery Hall, Paris. Issue of September 7, 21 and 28, 1889.

LXXIV.—Standard Cars used on New Croton Aqueduct. Illustrated. Issue of October 12, 1889.

LXXV.—Erection Adjustment of the Kanawha River Bridge. Illustrated. Issue of October 26, 1889.

LXXVI.—An Adjustable Pile Driver and Derrick. Illustrated. Issue of November 9, 1889.

LXXVII.—Construction of Inverts and Side Walls on New Croton Aqueduct. Illustrated. Issue of November 16, 1889.

LXXVIII.—Erection of Buffalo Truss Viaduct. Illustrated. Issue of December 14, 1889.

LXXIX.—Construction of Arches on the New Croton Aqueduct. Illustrated. Issue of December 14, 1889.

LXXX.—Erection of St. Paul High Bridge. Part I. General Diagram and Viaduct Erecting Traveler. Illustrated. Issue of December 21, 1889.

LXXXI.—New Croton Aqueduct Compressed Air Plant. Illustrated. Issue of December 28, 1889.

LXXXII.—Erection of St. Paul High Bridge. Part II. False Work and Traveler for River Spans. Illustrated. Issue of December 28, 1889.

LXXXIII.—Lighting the Croton Aqueduct. Issue of January 11, 1890.

LXXXIV.—Erection National Gallery, Berlin. Illustrated. Issue of January 11, 1890.

LXXXV.—The Van Buren Bridge Piers. Part I. General Description of Location, Structure, Methods, Progress and Materials. Illustrated. Issue of January 11, 1890.

LXXXVI.—Ventilating Croton Aqueduct. Illustrated. Issue of January 25, 1890.

LXXXVII.—Van Buren Bridge Piers. Part II. Illustrated. Issue of February 8, 1890.

LXXXVIII.—Croton Aqueduct Pumps. Experiments relating to Hydraulics of Fire Streams. Issue of February 22, 1890.

LXXXIX.—European Bridge Erection. Illustrated. Issue of March 1, 1890.

XC.—Erection of Court Street Bridge at Binghamton, N. Y. Illustrated. Issue of March 8, 1890.

XCI.—Sidewalk Protection during Building Construction. Illustrated. Issue of March 15, 1890.

XCII.—House Builder's Derrick. Illustrated. Issue of April 5, 1890.

XCIII.—Drilling, Blasting and Timbering the Croton Aqueduct. Illustrated. Issue of May 17, 1890.

XCIV.—Raising a Block of Brick Houses. Illustrated Issue of May 31, 1890.

Nos. I. to XVII. only obtained in Vol. XV. of THE ENGINEERING AND BUILDING RECORD. Price $3.00.

ADDRESS, BOOK DEPARTMENT,

THE ENGINEERING AND BUILDING RECORD,
277 PEARL STREET, NEW YORK.

THE frequent receipt of requests from all sections of the country for copies of the Architectural Supplements that have appeared during the past few years in THE ENGINEERING AND BUILDING RECORD's critically selected architectural series, has induced us to collect all available original sheets of these special illustrations, as issued with each number, and to offer them for sale in lots of twenty, neatly and carefully rolled and sent postage free, on receipt of one dollar in postage stamps or by postal order.

Address, BOOK DEPARTMENT,

THE ENGINEERING AND BUILDING RECORD,
277 Pearl Street, New York.

BRUCE PRICE, New York, on January 28, 1886, *wrote*: "*The illustrations issued in your publication are the best to my mind published in this country, and must, as a critical resource, be of the greatest service to my profession.*"

THE ENGINEERING & BUILDING RECORD
AND
THE SANITARY ENGINEER.

A JOURNAL FOR THE ARCHITECT, ENGINEER, MECHANIC, AND MUNICIPAL OFFICER.

Entered according to Act of Congress in the year 1890, by HENRY C. MEYER, in the Office of the Librarian of Congress at Washington, D. C.

VOLUME 22. NUMBER 19. PUBLISHED EVERY SATURDAY. 277 PEARL ST., NEW YORK.

NEW YORK, OCTOBER 11, 1890.
LONDON, OCTOBER 25, 1890.

SINGLE COPIES, TEN CENTS. Subscription, $4.00 per year in advance, post paid. IN AMERICA.
Subscription, 25*s*. per annum in advance, post paid IN GREAT BRITAIN.

THE ENGINEERING & BUILDING RECORD, *conducted by* HENRY C. MEYER, *is published every Saturday at* 277 *Pearl Street, New York* (*P. O. Box* 3037). *Its opinions upon all technical subjects are either prepared or revised by specialists.*

OFFICE IN GREAT BRITAIN,
92 & 93 FLEET ST., LONDON.
PHILADELPHIA OFFICE 1050 DREXEL BUILDING.
TERMS, $4 PER YEAR, IN ADVANCE.
25*s*. in GREAT BRITAIN. Other Foreign Countries $6.
Postage Paid.

SPECIAL OFFERS.

DOUBTLESS many of our subscribers have a friend who thinks of subscribing to THE ENGINEERING AND BUILDING RECORD for the coming year, and as every paper, however successful it may be, desires to increase the number of its subscribers, the following offers are made, to hold good during October, November and December:

First.—Any present subscriber can have his subscription extended one year by sending us $7.25, accompanied by the name and address of a new subscriber who is not now buying THE ENGINEERING AND BUILDING RECORD of a newsdealer.

Second.—Any present subscriber can, under the conditions mentioned in first offer, have his own yearly subscription for $2 by sending us, with his renewal, two *new* names and $10, or for $1, by sending three new names and $13.

THE ENGINEERING AND BUILDING RECORD,
P. O. Box, 3037. 277 Pearl Street, New York.

THE PRESENTATION OF PAPERS BEFORE ENGINEERING SOCIETIES.

A NOTEWORTHY circumstance, connected with the New York meeting last week, of the American Institute of Mining Engineers and of the British Iron and Steel Institute, was the distribution, immediately before each session, of printed copies of some of the papers which had been prepared. So far as we are aware this was the first time in the history of the Institute of Mining Engineers, at least, that anything of this kind had been attempted, and it must be regarded as a decided step in advance of the customary and still partially retained practice of this and nearly all other engineering societies, of reading the papers in full at the sessions, and of being content with the necessarily limited and imperfect discussion of points which may suggest themselves to the attending members during the reading.

There seems, fortunately, to be a gradually growing appreciation of the fact that intelligent and comprehensive discussion of a professional paper cannot be conducted on the spur of the moment, but requires careful study of the subject, and that this can be made possible only by making the papers available previous to the time during which they are to be presented. The distribution of printed copies, as in this instance, secures not only this object, but further, makes it unnecessary to needlessly take up time at a meeting by allowing a paper to be read from beginning to end by its author. A brief abstract, setting forth the salient features, is all that is necessary.

In connection with this we cannot too strongly commend to the attention of all engineering societies the plan adopted several years ago by the American Society of Mechanical Engineers, and which has been found to give excellent results. All papers to be presented before that society must be submitted to a publication committee several weeks before the meeting for which they are intended. Upon acceptance, printed copies are prepared and distributed among those members desiring them, several days in advance of the meeting. A good opportunity is thus given for a careful study of the subject, and for preparing written discussions if desired. At the meeting, the author of each paper is permitted to present only an abstract of it, to take up not more than ten minutes, and in the resulting discussion each speaker is limited to five minutes. For written discussions ten minutes are allowed, and for the closing remarks the author is granted an additional period of five minutes. The advantages of this system have been demonstrated in the most striking manner. Every one who has attended one of the meetings of the American Society of Mechanical Engineers cannot have failed to be impressed with the thoroughly business-like character of the sessions, and the large amount of work which is crowded into a comparatively short period of time in virtue of this arrangement. The discussions, based upon mature consideration of the subject, are animated and to the point, and there is no flagging of interest brought about by long drawn out readings of papers which, however valuable they may be, cannot usually be intelligently followed if presented in the customary manner, and, therefore, of necessity must become somewhat wearisome.

The attempt at reform made last week by the American Institute of Mining Engineers has, undoubtedly, been prompted by the success of the Mechanical Engineers' methods and ought to meet with hearty encouragement. Other engineering societies, having a comparatively large number of papers to dispose of at their meetings, would also find it advantageous to follow the same plan. It enables the ready handling of a great volume of business in a short time, adds to the interest and value of the proceedings, and impresses upon the members the conviction of having spent the available time in the most economical and profitable manner.

THE RELATIONS OF CONSUMPTION TO WIDTH OF STREETS.

THE word "consumption" in the above title does not refer to expenditure of money, or to the rapidity of wearing out of pavements or of vehicles; but to the popular term for the disease known to physicians as "phthisis," or more specifically as "pulmonary tuberculosis." It destroys more lives in the United States in the course of a year than does any other disease, and in our large cities it causes about 14 per cent., or over one-eighth, of all the deaths. It is well known that the mortality from this cause is greater in some parts of cities than it is in others, and the reasons for this are of much practical interest.

Dr. H. S. Anders, in a paper recently published in the *University Medical Magazine*, calls attention to the fact that the width of streets seems to have some connection with local death-rates from consumption, basing his conclusions on a study of the deaths from this disease which have occurred in the Fifteenth Ward of Philadelphia during the fifteen years from 1874 to 1888. This ward includes an area of about one square mile, lying north of Vine and west of Broad Streets, and bounded on the west by Fairmount Park and the Schuylkill River. Most of it is well elevated and fairly drained. It presents great variety in the width of its streets, and the number of deaths reported as due to phthisis is comparatively large. Taking a map of this region, Dr. Anders marked upon it the precise location of 1,665 cases of death from consumption, and then, comparing the frequency of these with the width of the streets upon which they occurred, obtained the following results: "The number of deaths from phthisis on a very wide street is proportionately small as compared with those occurring upon almost any narrow street, and the same is true with reference to the aggregates of several wide and narrow streets. The mortality was low in streets of medium width, but very high in certain groups of small streets, and especially so in narrow streets closed at one end. Even narrow streets, only a block in length, show a remarkably large death-rate from phthisis." He refers to similar investigations, leading to similar conclusions, made some years ago by Dr. Arthur Ransome, in Manchester, England, and concludes that it is the defective change in the air in narrow streets which is the chief cause of the increased mortality, and that, therefore, street ventilation should be given special consideration by municipal engineers.

We have no doubt that the death rates are generally lower on wide streets and in houses facing open spaces than they are on narrow streets, alleys, and nearly inclosed courts, or *cul* *de sacs.* The English statistics on the healthfulness of large cities in England long ago demonstrated that the mortality was greatest where the houses are most closely packed, and Dr. Farr expressed this mathematically, by saying that the mortality in different localities is in proportion to the sixth root of their densities of population. We now know that this relation between death rates and densities of population is by no means a necessary and inevitable one within the ordinary limits, and that defective amount of open air space acts prejudicially in several ways besides merely preventing rapid change of air.

Phthisis is caused by the development and growth in the air passages of a minute vegetable organism, which forms rods, each about one ten-thousandth of an inch long, and is called *bacillus tuberculosis.* It can be cultivated on various substances if kept very warm, but so far as we know it does not grow naturally except in the living bodies of warm-blooded animals, including man. In many men and animals it does not grow at all under ordinary circumstances. It is transmitted to men and animals chiefly by its spores contained in matter spit up by men, or animals, affected with the disease. It may be transmitted by the flesh or milk of tuberculous animals, but so far as pulmonary tuberculosis is concerned, it is due in almost every case to the inhalation of dust carrying with it dried and pulverized sputa which contained the bacillus when it was expectorated. One of the things which strongly affects this bacillus is light. In the dark it can maintain its vitality for a long time, months at least, even when quite dry; but a few hours' exposure to full sunlight kills it, and so does a few days' exposure to full daylight. The illumination of living rooms, therefore, has an important influence on their healthfulness so far as phthisis is concerned, and this is one reason why narrow streets and alleys and back-to-back houses show high death rates from this cause.

Another reason is that in such narrow streets and alleys live the poorer classes, who shun ventilation of their living rooms in order to save fuel, and in whose families, crowded together in a few rooms, a single person affected with the disease is a specially dangerous source of infection. But if we cannot assign the precise share which impure air, insufficient light, uncleanly habits, etc., have in favoring the development of tuberculosis, it is at least fortunate that abundance of fresh air and light usually go together, and that in securing the one we usually obtain the other. Many poor families in cities cannot, unfortunately, have as much of these two great needs in their living rooms as they ought to have, but they can at least avoid the special danger which arises from allowing the sputa of a consumptive member of the family to dry upon the floor and to be scattered in dust through the apartment.

AN ELECTRIC CENSUS.

THE following electrical statistics are given in a recent issue of London *Iron*:

In 1837 the first practical telegraph was worked in England, after a crude attempt made in 1835 on a line of 13 miles between Paddington and Drayton. In 1884 a telegraph line was opened between Washington and Baltimore. In 1850 a copper wire insulated in gutta-percha was submerged between Dover and Calais, and the first submarine telegraph was laid by the late Mr. T. R. Crampton. There are now 942 submarine cables, exclusive of the seven Atlantic cables, with an aggregate of 112,740 nautical miles. The overland telegraph is already a world-wide institution, in which there is a total of 1,680,900 miles of wire, enough of the attenuated metal to go around the equatorial belt of the globe just thirty times. The number of words transmitted, the miles traveled, and the cash changing hands would tax the enumeration table. The United States have 776,500 miles of wire, and in 1889 no less than 56,000,000 messages were sent through the country. France has 220,890 miles of wire, on which in 1889 were transmitted 30,050,000 dispatches. Great Britain has 180,000 miles of metal line, and in 1889 sent 50,000,000 messages. Russia has spun out 170,500 miles, and in 1889 gave the operators 10,280,780 messages to dispatch. Australia has strung no fewer than 105,360 miles of wire across its surface, and transmitted in one year 12,000,000 messages. Italy has 19,500 miles, and has made an annual record of about 7,000,000 electric messages. Canada has 58,500 miles of wire, and did a business in 1889 of 4,027,581 dispatches. Egypt has 5,500 miles, and is in connection with India and England by submarine cables on which last year 1,600,205 communications were carried from one end of the world to the other. China has 5,500 miles of wire across Mongolia, and Japan owns no less than 16,500 miles, over which 5,000,000 messages were sent in one year. New Zealand has strung itself with 11,375 miles of metal cord, and dispatched 1,835,394 messages. Tasmania has 2,500 miles of telegraph wires. Persia claims, in partnership with European wires, about 6,124 miles. South Africa has a credit of 4,310 miles, and even St. Helena, the island prison of the great Corsican, has 13 miles of the universal wire cobwebbing its rocks. The telegraph systems of the world have unrolled the wire reel without stint, and if we add to the 1,688,900 miles used for telegraph purposes the wholesale appropriation by the telephone system, the sum total would be enormous.

AN HYDRAULIC CALCULATING RULE.

AN hydraulic calculating rule, invented by an English engineer, Arthur Honeysett, and made by W. F. Stanley, Holborn, W. C., England, is described in the London *Building News*.

The rule is made of boxwood, graduated with great nicety, and is about 16 inches long and 2 inches broad. It appears to be a very useful instrument, as it will greatly facilitate the labors of the engineer in calculating the velocities and discharge of sewers and pipes. Eight scales are marked on the rule, A, B, C, D, E, F, G, and H, the four last ones being made to correspond to four classes of co-efficients, according to the nature of the channel, the first class being for cement or smooth pipes, the second class for brick or ashlar, the third for rubble masonry, and the fourth for earth, river courses. By a sliding index the figure (marked 100) is brought opposite the value of the hydraulic mean depth on one of the lower scales corresponding to the nature of channel, then on another scale (marked D) will be found the velocities in feet per second due to the inclinations given on the slide, which comprise falls from 1 in 6 to 1 in 2,000, though inclinations flatter than the last can be obtained. To aid in adjusting the sliding index over the lower scales, a piece of talc, marked with a line, slides over the rule. By another adjustment of the slide the quantity discharged can be found. Scale A gives the square root of the fifth powers of values, by means of which the diameter of a pipe to discharge a given quantity can be found. Other tables at the back of the rule enable the engineer to find the area and hydraulic mean depth of segments of circular and oval conduits.

NOTES.

THE construction of the Niagara tunnel was commenced, with appropriate ceremonies, on Saturday last, October 4, C. B. Gaskill, President of the Niagara Power Company, turning the first sod.

SEVERAL disastrous explosions occurred at the Dupont Powder Works, near Wilmington, Del., on the 7th inst. A number of buildings were wrecked, and several lives lost.

THE work of the Mississippi River Commission, which has been sitting at New York, was completed on the 4th inst. Over $3,000,000 has been apportioned for the improvement of the lower Mississippi and its tributaries. The work of improvement will be begun as soon as the Secretary of War has approved the apportionment.

CHIEF ENGINEER FTELEY has reported to the New York Aqueduct Commissioners that a structure of less magnitude than the Quaker Bridge Reservoir, but large enough to furnish ample storage capacity for the next twenty years, can be built at smaller cost. The site he suggests is about a mile below the Croton Dam, and he recommends that such a dam as is proposed be built there immediately. The Aqueduct Commissioners will give a public hearing in the matter on October 27.

MEETINGS OF ENGINEERING SOCIETIES.

The AMERICAN SOCIETY OF CIVIL ENGINEERS holds its regular meetings on the first and third Wednesday in each month, at the House of the Society, 127 East Twenty-third Street, New York.

The BOSTON SOCIETY OF CIVIL ENGINEERS holds its regular meetings at the American House, Boston, at 7.30 P. M., on the third Wednesday in each month.

The WESTERN SOCIETY OF ENGINEERS holds its regular meetings at its hall, No. 67 Washington Street, Chicago, at 7.30 P. M., on the first Wednesday in each month.

The ENGINEERS' CLUB OF ST. LOUIS holds regular meetings in the club's room, Laclede Building, corner Fourth and Olive Streets, St. Louis, on the first and third Wednesdays in each month.

The ENGINEERS' CLUB OF PHILADELPHIA holds regular meetings at the House of the Club, 1122 Girard Street, Philadelphia.

The ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA holds regular meetings on the third Tuesday in each month, at 7.30 P. M., at its rooms in the Penn Building, Pittsburg, Pa.

The ENGINEERS' CLUB OF CINCINNATI holds its regular meetings at 8 P. M. on the third Thursday of each month at the Club rooms, No. 24 West Fourth Street, Cincinnati.

The CIVIL ENGINEERS' CLUB OF CLEVELAND holds regular meetings on the second Tuesday of each month, at 8 P. M., in the Case Library Building, Cleveland. Semi-monthly meetings are held on the fourth Tuesday of the month.

The ENGINEERS' CLUB OF KANSAS CITY meets in Room 200, Baird Building, Kansas City, Mo., on the second Monday in each month.

The ENGINEERING ASSOCIATION OF THE SOUTHWEST holds regular meetings on the second Thursday evening of each month at 8 o'clock, at the Association headquarters, Nos. 63 and 64 Baxter Court, Nashville, Tenn.

The CIVIL ENGINEERS' SOCIETY OF ST. PAUL meets at St. Paul, Minn., on the first Monday in each month.

The MONTANA SOCIETY OF CIVIL ENGINEERS meets at Helena, Mont., at 7.30 P. M., on the third Saturday in each month.

The CIVIL ENGINEERS' ASSOCIATION OF KANSAS holds regular meetings on the first Wednesday in each month at Wichita, Kan.

The NEW ENGLAND WATER-WORKS ASSOCIATION holds quarterly meetings in Boston at Young's Hotel.

THE CANADIAN SOCIETY OF CIVIL ENGINEERS holds its regular meetings on each alternate Thursday, commencing with the 9th of October, at the House of the Society, 112 Mansfield Street, Montreal.

The convention of the American Institute of Architects will be held in Washington, D. C., beginning on October 22, and continuing until the business has been completed.

A QUANTITY of mining machinery, comprising air compressors, rock drills, etc., was shipped to the Jehu Mines in China, last week, by the Ingersoll-Sergeant Rock Drill Co., of New York. Jonas Crabtree, an experienced mechanical engineer, was engaged by the company, and is now on his way to China to erect and operate the machinery.

A GOVERNMENT appropriation has been made for exhaustive trials of the Ericsson submarine torpedo gun.

OBITUARY

MARTIN ALLEN, Superintendent of Section 3 of the Erie Canal, died on the 8th inst., of pneumonia, aged 51 years.

THOMAS THOMPSON, one of the oldest architects in Elizabeth, N. J., died on Sunday, October 5. He was 71 years old, and had designed many fine houses in Elizabeth and its vicinity.

ANDREW PERRIN, died on October 7, at Rochester, N. Y. He was born in Conesus, Livingston County. He lived many years in Oil City and Titusville, Pa., where he served as Mayor two terms, and was favorably known throughout the oil country. He was 41 years old. Mr. Perrin owned large business interests in the oil country, and was manager of the Seaboard Pipe Line Company.

PERSONAL.

D. C. DUNLAP was recently appointed City Engineer, of Rockford, Ill.

SETH GREGORY, architect, of Aurora, Ill., will spend the winter in Tacoma and other cities in Washington.

HENRY C. ALLEN has been appointed to temporarily fill the office of City Engineer of Syracuse, N. Y., during the absence of H. W. Clarke, necessitated by ill health.

THE IRON AND STEEL MEETING.

As ALREADY stated in our last issue, the American Institute of Mining Engineers, with its British and German guests, left New York for Philadelphia on Saturday, October 4, Philadelphia being the first stopping place on the extended trip West, North and South, for which arrangements have been made.

Saturday was spent in visiting the Disston Saw Works, at Tacony, near Philadelphia, and in a trip by boat to Chester, Pa., and Wilmington, Del.

The special feature of Monday, October 6, was the excursion to the works of the Phœnix Iron Company, at Phœnixville, Pa. A train, furnished through the courtesy of the Reading Railroad Company, left Philadelphia in the morning, and a special train had also been arranged to leave New York, to convey a number of New York representatives of the iron trade and of the engineering and architectural professions to the works.

Those who did not go to Phœnixville visited a number of other establishments in and near Philadelphia, among them the Camden Iron Works, at Camden, N. J., the Baldwin Locomotive Works, at Philadelphia, the Edgemoor Iron Company's Works at Wilmington, Del., and the Southwark Foundry and Machine Company's Works, at Philadelphia.

Early on Tuesday, October 7, the engineers left Philadelphia for Lebanon and Harrisburg, visiting the various large iron and steel works at these places,

Wednesday was devoted to the industries of Altoona and Johnstown, prominent among them the Pennsylvania Railroad Company's shops at the former, and the Cambria Iron Works at the latter town. Pittsburg was reached in the evening.

On Thursday and Friday mornings, sessions were held at Pittsburg, for the reading and discussing of professional papers.

THE Inca's Bridge in the Andes, as described by Theodore Child in *Harper's Magazine*, is simply an arch of stratified shingle, cemented together by deposits and petrifications from the hot springs which bubble up all over the neighboring bluff, the river Cuovas having eaten its way through the shingle and falling in a cascade below. The bridge is 66 feet high, 120 wide, and varies from 20 to 30 feet in thickness, and seen from below the bridge it is found to be covered with yellowish stalactites, more curious than beautiful.

BOOK NOTICES.

THE THAMES RIVER BRIDGE AND APPROACHES AT NEW LONDON, CONN. By Alfred P. Boller, Chief Engineer. Size, 10½x14 inches; 60 pages.

We are indebted to Mr. Alfred P. Boller, Chief Engineer of the Thames River Bridge, at New London, Conn., for a copy of the above volume, which has just been issued, and which, virtually, is his report upon the construction of the bridge and its approaches to the General Manager of the New York, Providence and Boston Railroad, for which it was built.

Concerning the bridge itself we need say nothing here, as comprehensive extracts from the book are given elsewhere in this issue. The work opens with an historical account of the enterprise from its inception; this is followed by a general illustrated description of the bridge and of the methods of construction followed, while eight appendixes and 13 folding plates of illustrations make up the concluding portion. To the engineer the appendixes are of more than general interest, being, with a few exceptions, devoted to copies of the specifications covering the construction of the superstructure and of the foundations and the masonry, and to a mass of highly interesting and valuable figures, in tabulated form, giving the weights of metal in the different truss spans, and the results of tests of the structural material used.

The tables represent a prodigious amount of testing work, and their importance can scarcely be overrated, placing, as they do, within reach, in condensed form, a large quantity of data on the physical and chemical properties of the metals employed. Thus, Appendix No. 7 contains the results of 33 tests of full-sized ¾ inch. open hearth steel eye-bars, giving all the particulars obtained which are likely to be of any possible practical value; and Appendix No. 8 is devoted to tests of finished material, embracing open hearth and Bessemer steel bars, plates, L's, channels, and I-beams, and to tests of the iron used. The peculiar value of these tables to the engineer who is interested in structural iron and steel work scarcely needs pointing out.

The folding plates, already mentioned, illustrate various details of the bridge, both superstructure and foundation work, profiles of soundings across the Thames River, and of part of the line from New London.

The importance and value of the report make it all the more to be regretted that the binding is not of a more substantial and protective character, being practically ordinary trade catalogue binding. This defect, however, can be easily remedied at slight expense by the purchaser.

THE RAIYAN CANAL.

A PAPER on the Raiyān Canal was contributed to the British Association for the Advancement of Science, at its last meeting, by Mr. Cope Whitehouse.

The general character of this canal, which it is intended to construct between the Valley of the Nile and the Raiyān depression, at a point about 80 miles south of Cairo, was explained at a previous meeting. The proposed works have now been elaborated in detail, (1) the size of the basin; (2) the section of the canal: (3) the water-surface levels of the Nile; (4) the minimum level of the Nile in flood; (5) the works to the west of the Nile Valley—excavations, earthworks, pitching, and masonry; (6) the works in the Nile Valley for the passage of existing canals, drains and railways under and over the Raiyān flood-canal; (7) the time required to fill the reservoir; (8) the quality of the water stored, tables, maps, sections, photographs exhibited, and estimates given. With an 80-meter wide canal the flood could be lowered at 50 centimeters per 24 hours, and the reservoir, 250 square miles in area, and 220 feet in maximum depth, filled to the level of + 27 meters above sea in three years.

The total cost is estimated at less than £1,589,000. The duty of the reservoir would be to raise the minimum flow of low-Nile from about 9,000 feet per second to 30,000, and fix a maximum for high-Nile. The results anticipated would be practically to double the present cultivated area and agricultural output, with large extension of internal navigation in the Delta.

AT the meeting of the Executive Committee of the Grant Monument Association on the 6th inst., at New York, the special Committee on Site reported in favor of a plot on Riverside Drive at One Hundred and Twenty-third Street. It is only a short distance above the place where the General's body now rests.

THE scant water supply of Waterbury, Conn., is said to occasion some anxiety. The present reservoirs were built 20 years ago, and were calculated to supply all demands for 10 years. The city is claimed to be more than three times as large as it was then, and still there has been no increase in the water supply.

THE A. L. HOLLEY MEMORIAL.

ONE of the features of last week's meeting at New York of the American Institute of Mining Engineers and the British Iron and Steel Institute was the unveiling, on Thursday afternoon, of the bust of Alexander Lyman Holley, at Washington Square.

In a brief speech, as the chairman of a committee representing the American Institute of Mining Engineers, the American Society of Mechanical Engineers and the American Society of Civil Engineers, ex-President Bayles of the Health Board, formally presented the memorial to the city of New York. After Mr. Bayles had spoken, and while the Seventh Regiment band played "America," Alexander Holley Olmstead, the six-year-old grandson of Mr. Holley, pulled the cord and the American flag fell to the ground, revealing the clear-cut features and fine proportions of the bust. Then Mr. Gallup, the President of the Park Boark, in behalf of the city, accepted the gift in a brief speech.

Previous to the ceremony an address on Alexander L. Holley was delivered at Chickering Hall by Mr. James Dredge, one of the editors of *Engineering*, of London. Mr. Dredge prefaced his address with the reading of letters in praise of Alexander L. Holley from James Forrest, the Secretary of the British Institution of Civil Engineers, and Sir Henry Bessemer. From the address we extract the following:

> In 1857 I was the first person to shake hands with Holley on his arrival in England. Twenty-five years later I was the last Englishman to shake him by the hand in London, when we said our final farewell. You cannot imagine the effect which the sudden apparition of the two young Americans, Holley and Colburn, in the gloomy London office, had upon me. They appeared to me like beings from a superior world, so unlike were they to any persons I had ever met before. Even with my untutored and crude power of perception, I could feel that they were surrounded with an atmosphere of energy and intelligence; that they were overflowing with vitality. The one seemed to me a spirit of darkness, the other a spirit of light; and both so immeasurably my superiors that I could do little more than gaze on them in wonder.
>
> When their brief visit came to an end, and they returned to New York, most of the light went out of my life, though their influence remained behind, especially that of Holley, whose bright individuality rested with me as an ideal, which I might, perchance, with time and constant effort, feebly imitate. The following year Zerah Colburn returned to London alone. He became the editor of *The Engineer*, and I, having sought him out, had the privilege of being closely and intimately associated with him until the curtain fell upon his tragic end. As no doubt you know, after he returned to England in 1858, he made his permanent home there, with the exception of a few months in 1860, which he passed in Philadelphia. You are also aware that it was he who founded *The London Engineering* in 1866. Into the management of this journal he threw, for the first three years, the whole force of his great erratic powers. After their first visit to London, and their joint publication of the volume on European railways, Holley and Colburn, without becoming actually estranged, had but little in common. The dark and fiery genius of the one was, in fact, so opposed to the trained talents and noble soul of the other, that it was impossible for any real and lasting sympathy to exist between them.
>
> With Holley's return to America in 1858, or shortly afterward, began the journalistic epoch of his career. For some years he was a valuable and industrious contributor to the New York *Times*, and certainly never before or since has any daily newspaper been so fortunate in the services of an engineering contributor. In 1859, and again in 1860, he visited England, chiefly to write upon a subject which was then attracting the attention of the civilized world—the "Great Eastern." This business brought him into intimate contact with the engineers of that vessel, Brunel and Scott Russell; with the last named the acquaintance ripened into a warm personal friendship which always remained. The New York *Times*, *The Railway Review*, inventions connected with the steam-engine and permanent way, and miscellaneous literary employment kept Holley closely occupied, and brought him plenty of reputation, though but little money, until the War of Secession. It is needless to say that Holley, like a good patriot, offered his able services to the Government, and it is interesting to add that his offers were uniformly declined. It was during this great national crisis that Holley, while still holding on to his main support—a brilliant and facile pen—had the opportunity of taking up work more congenial to him. He was employed by Mr. Stevens in 1862 to visit Europe in order to obtain information that might be useful in the construction of the Stevens battery, on which so much time and money, as well as skill, were wasted. Mr. Scott Russell, who at that time had considerable interest in naval and military circles, rendered Holley good service in obtaining for him introduction and information, while his own presence of mind and coolness often stood him in good stead in obtaining access to places the official doors of which were closed against him. It was this new connection that turned his mind to the production of that important hand-book on "Ordnance and Armor," which, when completed, was destined to remain for so many years the standard book of reference on the subject. Like every piece of work to which Holley set his hand, this treatise bears on every page evidence of his capacity for taking infinite pains. The objection has been made by friendly critics in this country, that "Ordnance and Armor" was scarcely worthy of its author. I do not agree with this criticism, and in this I am sustained by one of the ablest practical designers of artillery in the world, M. G. Canet.
>
> When this book was published, the art of heavy gun construction was far more tentative and experimental than it is now, and the classified collection of all information available up to the date of its publication served as a great aid in advancing a science then in its infancy. The strictly literary period of Holley's career was now drawing to a close, and though he could never, as long as he lived, abandon his innate love for writing, he was no longer compelled to rely on his pen as a means to live. In May, 1863, he finally decided upon turning his talent and energies into another channel, one that was destined to lead him to fame, and moderate prosperity.
>
> The practical value of the Bessemer process for manufacturing steel had by this time become widely recognized, and it followed almost as a matter of course that Holley, who was always on the lookout for some new and good thing, felt intuitively that the time for which he had so long waited had at last arrived. The story of the Bessemer process was at that time no new one. Seven years before, at the Cheltenham meeting of the British Association for the Advancement of Science, Mr. Bessemer had made the first public announcement of his invention. The title of the paper excited derision; its reading, wild enthusiasm. Mr. James Nasmyth said of the samples shown to the astonished audience, "Here are true British nuggets." A wave of excitement passed over the country; one result of this paper was that almost immediately a sum of $250,000 was offered for the English patents; another, that within a month £28,000 had been paid for licenses to work the process in Great Britain alone. Then swiftly followed a fierce reaction, consequent on failures due to hasty experiments and crude trials. Abuse of the inventor was as hearty as the praise had been fulsome a few weeks before.
>
> The Sheffield Bessemer Works in 1864 were on a very small scale; they comprised only two three-ton converters and a corresponding plant. Holley came from America upon this business as the representative of Messrs. Corning, Winslow & Co., a firm that was afterward changed to Winslow, Griswold & Holley. His mission was to purchase the Bessemer patents for the United States; to learn the process; and afterward to inaugurate the new industry at home. As he said, that journey was no pleasure trip; but he came back successful on all points, and the following year the works at Troy were built.
>
> As is the case with so many great inventions, a number of active minds were turned toward the manufacture of steel, stimulated thereto by Bessemer's success and his reputed failures. Prominent among these in the United States was W. Kelley, of Eddyville, Kentucky, and your talented countryman, W. F. Durfee, addressed himself to the practical development of this invention; it was he who constructed the experimental steel works at Wyandotte, Mich. This was in 1862, the year of the great international exhibition in London, where Holley had ample opportunity of studying the products of the Bessemer converter. We may be certain that what he saw there convinced him of the importance of the process for the United States. His judgment was confirmed by that of Zerah Colburn, who, with his usual foresight, had some time before become a strong advocate of the process. Writing in *The London Engineer* in 1862, Zerah Colburn said: "The fact that as a substitute for wrought-iron, at least where facility of welding is not of a special consequence, the Bessemer metal is now known to be of established, trustworthy character, is of itself a most important one, and as those who fully know the process are aware that ingots can be turned out by it at £6 a ton, and finished rails at less than £10, we have only to await the time when through competition this metal has been cheapened to an extent which will insure its general application for the many purposes to which it is so admirably fitted."
>
> After the return of Holley to America in 1864 the Troy works were started, and the first charge of Bessemer metal was made on February 16, 1865. Let me refer you to R. W. Hunt's interesting paper on the original Bessemer steel plant at Troy, read before your Society of Mechanical Engineers in 1884. You will see from it that Troy was only a small works with two 2-ton converters, but such capital steel was produced that enterprise and capital were convinced. During the month of May, 1865, less than twelve weeks after the works were started, eighty charges were made, giving 118 tons of steel with 16.7 per cent of loss; immediately after this the works were extended by the installation of a plant that included two 5-ton converters; Mr. Z. S. Durfee assumed the charge of the establishment, and Holley proceeded to construct steel works in other parts of the country, commencing with those of the Pennsylvania Steel Company at Harrisburg.
>
> The thorough efficiency of the Bessemer process having been thus demonstrated, there was no limit to the supply of capital required for the erection of steel works, and Holley rapidly found himself almost unable to satisfy the demands made upon him for designing and starting new establishments. He, however, never knew what it was to have too much occupation, and the finest steel works in your country bear evidence of his skill and industry, those of North Chicago and Joliet; the Edgar Thomson Works at Pittsburg; the Vulcan Works at St. Louis; the Cambria, the Bethlehem, the Scranton and other works, were built under his instruction and from his plans. But more than this, Holley completely modified the details of the Bessemer process as he had learned it in England; he adapted it to the special requirements of the American manufacturer, who was enabled, through the modifications he designed, to produce those stupendous outputs of steel the records of which were so long received in England with incredulity.
>
> So the busy years passed, bringing with them a rich, if tardy, harvest of fame to Holley. He continued to be recognized as the one great authority in America on Bessemer steel; in Europe his reputation stood nearly, if not quite, as high. We all remember the prominent part he took in the Centennial Exhibition of 1876; his admirable reports on the iron and steel exhibits of that year, and which were followed by a long and masterly series of articles on the steel works of the United States—a series which unfortunately remained unfinished. Some of us have had the privilege of studying his annual and confidential reports on the steel manufacture of the world. The reports are marvels of technical skill and labor; they attest also the unlimited confidence which he commanded both at home and abroad; in the steel works of Europe as well as those of the United States. They were the result of periodical visits to England and the Continent, and were, during the last years of his life, prepared solely for the use of the Bessemer Association, with which he had entered into confidential relations. The gates of every steel works in Europe were open to him, and from him no manufacturers' secrets were withheld. It was quite a unique position which he then occupied, one for which his long training, high intelligence and perfect integrity absolutely fitted him. Manufacturers knew well that their secrets were safe in his hands; that if they gave him much, he brought still more to them; that his visits were always useful and suggestive, and that the exchange of American experiences for their own never left Holley their debtor. There was also another aspect to these annual visits. Time, hard work, and the cares of a busy life, had never withered the great charm of Holley's character, but, on the contrary, his personal influence and indefinable power of attraction had increased with years. He was loved as much as he was admired; he was as popular in France, in Germany and in Belgium, as he was in England or the United States.
>
> The professional honors that were so fully his due fell thickly enough on him during the later years. He was elected president of your Institute of Mining Engineers in 1875; he was vice-president of your Society of Civil Engineers in 1876; he founded your Society of Mechanical Engineers, of which society you did me the high honor to elect me an honorary member; in 1877 he became a member of the Institution of Civil Engineers, a body which we in England are proud to regard as the parent of all the Anglo-Saxon engineering societies.
>
> Holley was proposed as a member of the Institution of Civil Engineers by the late Sir William Siemens, and was seconded by a long list of well known and famous men in the profession; they were F. J. Bramwell, E. A. Cowper, T. R. Crampton, James Ramsden, J. T. Smith, Alexander Brogden, B. Baker, John Hawkshaw, W. H. Barlow, Charles Hutton Gregory, Douglass Galton, I. Lowthian Bell.
>
> Holley was also a member of the Iron and Steel Institute of London In 1875 he was appointed a member of the United States Board for testing structural materials; in 1879 he became a lecturer on the metallurgy of iron and steel at Columbia College, and in 1878 he was given the degree of Doctor of Laws.
>
> It was early in the summer of 1880 when Holley received the first warning that his career was drawing to a close. Twenty-five years of life at high pressure had told on his constitution, though his energy and magnificent mental powers remained unaffected.
>
> It was my privilege to pass many hours by Holley's bedside during this long period of trial, and if my presence and his knowledge of the constant solicitude of his very numerous friends in London afforded him some consolation; his fortitude, his patience and his calm endurance not only called forth our constant admiration, but taught a lesson I can never forget; an example few of us can hope to follow. It was very long before the faintest ray of hope threw a gleam upon that sick bed; not until after he had been absolutely condemned by the highest medical opinion. I believe that nothing but his indomitable determination, which never flagged, saved his life. He had from the first a fixed resolution to live, and I think he never once lost confidence. Some of you at a later time saw a similar scene enacted, but then, alas! he was able only to keep death at arm's length for a few hours instead of repelling it altogether. It was during this period that I learned the inner aspect of Holley's character. It was no seamy side that was thus exposed to me; but, on the contrary, great and gentle virtues, combined with an absolute trust that all was well, which showed the noble gentleman and the true Christian. The closer death approached, the more resigned he grew. "So far as I am concerned," he would say, "it matters nothing; I have done my best with the powers that I possessed, not for money or ambition, but because I just had to do my best. And it is impossible for me to die for another 18 months; those I leave behind me must be provided for, and I can do that easily in a year and a half."

THE TRANS-ANDINE RAILROAD.

THE year 1892 will probably be signalized in South America by a most interesting event in civil engineering and in international overland commerce. This will be the completion and opening of the Trans-Andine Railroad, the first across the continent of South America. It is 19 years since this work was begun, and it is now confidently expected that it will be finished by the beginning of 1892. The road is to run from Buenos Ayres to Valparaiso, a distance of 871 miles. There are now 640 miles of it finished at the Buenos Ayres end and 82 at the Valparaiso end. Of the remaining 149 miles about one-third is practically complete and the rails laid. The passage of the Andes is accomplished at the Cumbre Pass, which is 13,045 feet above the sea level. The railroad, however, does not reach the summit of the pass, but pierces the mountains by means of a tunnel more than three miles long, at an elevation of 10,450 feet above the sea. The grades are, of course, very steep; for a considerable distance the rise is more than 422 feet to the mile, or one foot in every 12½. On this portion of the line a rack rail is employed similar to those on the Hartz and other mountain roads. One unfortunate feature of the road is the diversity of gauges adopted. The different sections of the road have been built by different companies, and each company has its own gauge.

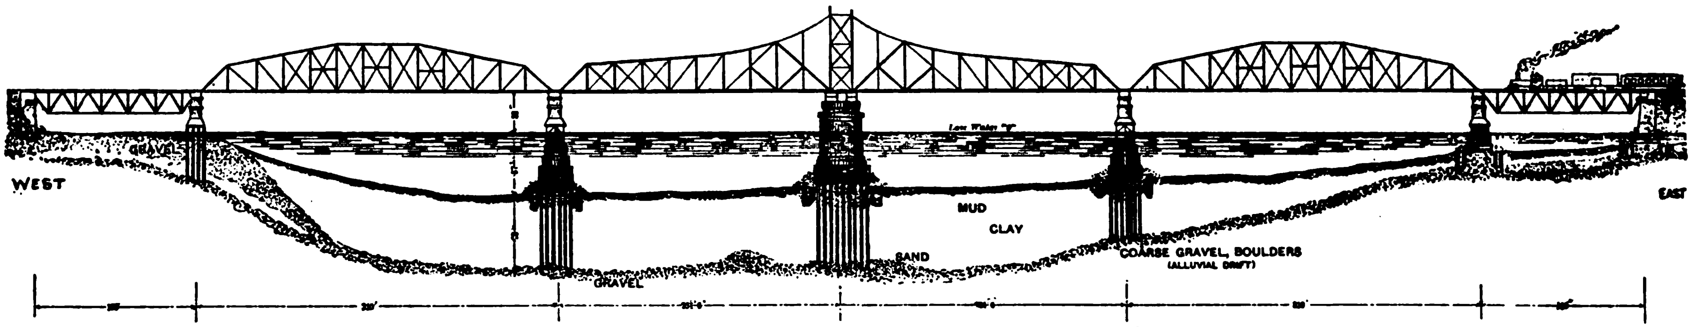
Architecture and Building, of October 4, 1890, is a special issue, devoted, in a great part, to the subject of modern school-house design. Besides a large amount of descriptive matter on the subject, there are 13 plates of illustrations showing various proposed and executed designs.

THE THAMES RIVER BRIDGE.

FROM the just-issued report of Alfred P. Boller, Chief Engineer of the Thames River Bridge, at New London, Conn., to J. W. Miller, General Manager of the New York, Providence and Boston Railroad, on the construction of the bridge and its approaches, we take the following particulars:

Ever since the establishment of the "Shore Line route" between New York and Boston, about 1860, the desire to replace the ferry over the Thames River, at New London, with a bridge has been ever present with the interested corporations forming the line. Thirty years ago, the then engineer of the "Stonington Road," Mr. A. M. Matthews, was engaged in making surveys for the purpose, and did locate a line of approach from the Stonington road to the most probable location of the bridge crossing, dictated by local and topographical considerations. The soundings made through the ice by Mr. Matthews, during the winter of 1859, disclosed such a depth of water and of mud before hard bottom was reached as to force the abandonment of the project, it being one beyond the engineering and financial resources of the day. Nothing further was done in the matter until the winter of 1882, when the great development of the Shore Line traffic impelled the group of roads forming the line to make another effort to attain the long desired bridge, which the marvelous development of modern engineering and the command of large financial resources made now a possible enterprise. Application was made, accordingly, to the General Assembly of the State of Connecticut, for authority to bridge the Thames River, and, on April 6, 1882, a bill was finally approved, "Authorizing the New York, Providence and Boston Railroad Company* to bridge the Thames River and extend its lines."

THAMES RIVER BRIDGE,
N. Y., PROV & BOSTON R. R. NEW LONDON, CONN.



The whole work, including right of way,* was estimated to cost one and a quarter million dollars, the plan of the bridge being for single track, and the approaches double track. All technical and legal questions being settled, the financial one alone remained for solution, and negotiations were commenced between the several interests involved for an apportionment of cost of building the bridge, and other matters incidental to a joint ownership of such a structure. Finally, through the exertion of Mr. George M. Miller, Vice-President of the New York, Providence and Boston Railroad Company, that corporation determined to shoulder the whole financial burden of building the bridge, and in February, 1888, notified Mr. Boller to at once prepare for the commencement of the work, and to make comparative estimates for both single and double track structures, as it was exceedingly desirable to avoid a break in the double track line. As the original estimate for a single track structure had been made on a most liberal basis, on higher market prices than now ruling, and as the substructure work and masonry only required a slight expansion to meet double track requirements, to say nothing of the advance in the art of bridge building and the use of steel, even in the short interval of four years, it was computed that a double track bridge could be covered very nearly, if not quite, by the original estimate. The plans and specifications were modified accordingly, and invitations to tender for the whole work on a unit basis were issued to a selected few of the bridge building firms of the country. After a careful canvas of the bids submitted, the work was awarded to the Union Bridge Company, of New York, under a contract dated April 6, 1888.

During the succeeding summer, a relocation of the approaches was made, purchases of right of way vigorously prosecuted, and the whole work put under contract in the early fall, the company reserving to themselves the ballast-ing and track laying.

GENERAL DESCRIPTION.

The Thames River is properly an arm of Long Island Sound, extending some fourteen miles inland up to the city of Norwich, at which point empty into it the Shetucket and Yantic Rivers, draining steep and precipitous water-sheds, as does the Thames River itself, on either side, to within a short distance of its mouth. The Thames is a broad stream, with irregular shore lines for about one-third of its length from its mouth, whence it rapidly contracts to its head at Norwich. Winthrop's Point juts out into the river about three miles from the Sound, contracting the stream to a width of about 1,500 feet, and affording an upper and lower harbor, in either one of which the deepest draught vessels can anchor. The current is purely a tidal one, save when increased at the surface during spring freshets, or seasons of heavy rainfall, when the tributary streams are running abnormally full.

The rise and fall of the tide between mean high and low-water mark is $3\frac{1}{10}$ feet, with an extreme of about 6 feet at spring and neap tides. The bottom of the river is that characteristic of a tidal estuary, commencing with mud, stiffening through various degrees of consistency into clays, clay and fine sand mixed, clay, sand and shelly fragments, into pure sand, thence into gravel, increasing in coarseness until the boulders of the alluvial drift are reached, or ledges of the underlying rock, hard bottom in consequence being very irregular.

These borings and soundings were performed by Messrs. Spielman & Brush, civil engineers, of Hoboken, N. J., and were made on the driven well principle of forcing a jet of water down a small pipe within a pipe of larger bore, the jet returning upward in the annular space between the pipes, carrying with it the material penetrated, which may be caught in vessels for examination and record. The pipes used were of ¾ and 2 inches bore for the inner and outer pipes respectively. This method, while a dangerous one to draw deductions from under many circumstances, where fine material may be washed up with no suggestion of a coarser one through which the tube might be passing, and by the washed-up samples being of an entirely different consistency from the material in *place*, still, in cases of this kind, the method serves an admirable purpose, since the geological character of the crossing could be determined from the surrounding country and from the well-known laws that govern deposits in streams. The extent of the deposits could be accurately determined, while their consistency could be judged in the light of the geological facts, and driving of test piles. The method is a rapid one, the deepest borings not requiring over a day, while from two to five borings were made where shallower. When the work was actually commenced, the upper mud proved to have much greater consistency than the borings indicated. It is of a peculiarly tenacious character, and stood readily on a slope of one to one, when dredged out for settling the cribs.

Teredo and Limnoria.—The operations of these destructive creatures are most entirely confined to the lower harbor, and even there they are only moderately active. In the waters in and around New York, creosote has proved a perfect barrier against them. But it is essential that the creosoting should be properly done, and preferably a product of coal tar, there being a considerable difference of opinion about the efficacy of that obtained from wood distillation. The creosoted material used in the Thames River Bridge is impregnated with fourteen pounds of the oil to the cubic foot, under a pressure of 150 pounds per square inch, after the timber had been heated up to 250° Fahr. in a vacuum of 26 inches.

Location of Piers.—Less than three deep-water piers were unavoidable, involving at best long spans which would be in harmony also with probable government requirements. The arrangement of piers adopted provides for a Draw span 503 feet long, flanked on either side by a span of 310 feet and 150 feet, respectively, center measurements.

Foundations.—The financial limits, within which the enterprise would be a feasible one, made the study of the piers and their founding of the leading importance, involving questions of the gravest consideration. The stability and permanence of foundations in water are of the first importance, involving the placing of materials at great disadvantage as compared with work on land, and in them a close economy cannot prevail. The west abutment foundation and that for Pier I. are simple in their character, requiring no special comment. In building the foundation for Pier V. and the east abutment the soft material was dredged to hard bottom (boulders and gravel), solid double walled square timber curbs were sunk surrounding the foundation area, which was filled in with concrete, lowered in wedged-shaped buckets of a cubic yard capacity, placed and leveled by means of a diver. The submarine concreting was carried up to the level of the original river botton, and surfaced off for the reception of the masonry platform. This concrete was made extra rich, two and one-half barrels of Portland cement to the yard of gravel being used, instead of two barrels, as provided for in open air concreting. The borings had only reached rock or boulders, under Piers II. and IV., and then at depths of 130 feet, and 100 to 120 feet respectfully, below datum (mean low water), with deposits of from 60 to 75 feet overlying the rock. At Pier III., the borings were carried to gravel and boulders, without reaching any suggestion of ledge rock, and the different borings taken were of very irregular depth. To reach the hard bottom, as the borings disclosed, by any of the pneumatic methods (excepting possibly at Pier IV.), was out of the question. Human labor could not be carried on under the enormous pressures involved, to say nothing of the prodigious cost if practicable. To reach hard bottom through an open caisson either of metal or timber, sunk by means of internal dredging and weighting, and filling up the voids created with concrete deposited through the water was prohibited through the cost, if indeed there were not grave questions as to the integrity of the concrete so deposited, and the great difficulty, if not impossibility, of dredging to a satisfactory bottom, particularly at Pier III., where the boulders were very irregular. To have stopped short of the gravel, boulders or rock, would involve a foundation on clay, which was not considered prudent. The use of isolated cylinders was considered and abandoned, if for no other reason than the great unbraced depth there would be from low water, to where they would be firmly held in the river bottom, some 70 to 80 feet. The only remaining method of founding which could be considered, and which was adopted, was that of a pile foundation, on which the masonry should be sunk in open caissons, which, owing to the unprecedented depth of water and material, involved novel methods of procedure. The piles must be driven from 100 to 130 feet below water—they must be driven true and straight; and cut off horizontally from 45 to 60 feet below water. They must be grouped in such a mass as to act as unit, and well collared at their upper ends, through the upper stratum of the mud, too soft for lateral support. They must be protected against the possibility of attack by marine worms. It was deemed judicious to adopt ten tons as the extreme loading on the piles, and to drive them with 4,000-pound hammer, with a short fall and rapid blows. The plan contemplated the sinking of a massive square-timbered, double wall curb, some 18 to 20 feet below the bed of the river, and surrounding the piled area, the mud within the curb being dredged out, and replaced with sand filling after the piles were driven. Such a filling thrown in loosely from above, would run in and fill every crevice and void among the piles, and embraced by the crib. The compacting of the bottom by closely driven piles, and the frictional support the piles afford to the narrow columns of sand, will, it is believed, prevent any substantial subsidence of the sand through the stiff mud and clay on which it rests. It was the original intention, when this plan was first thought out and adopted, to handle the work from a subsidiary staging, surrounding the foundation area on three sides, and by means of overhead trusses, to control the various operations of dredging, sinking the curbs, etc. But as that was a great expense, it was concluded, upon the revival of the enterprise, to abandon such temporary aids and save the cost towards the double track structure now desired, and boldly perform the work in the open river, with such aids as the permanent guard fenders would afford. In settling the curbs, it was first thought practicable to weight them down into place by dredging the material from within, but after testing the question on the curb for the east abutment, that method of procedure was abandoned, as the mud proved more tenacious, and had greater supporting power than the original borings indicated—and to have carried out the above plan would have involved extensive ballast pockets being built up on top of the curbs.

---

*The Boston and Providence Railroad was completed to Providence in 1852. The Stonington Line to New London in 1858. The Shore Line, from New Haven to New London, was opened in 1852.

The dredging was therefore performed as an independent preliminary operation, with a clam-shell dredge, and carried down 18 to 23 feet below the river bottom, the material standing on a slope of one to one—being below datum (mean low water), 77 feet at Pier II., 68 feet at Pier III., and 58 feet at Pier IV.

The curbs are framed from 12x12 hemlock timber, thoroughly drift-bolted together, and consist of a double-walled rectangular frame work surrounding an open area to contain the piling. These walls are 8 feet apart, and form, with a uniting bottom, a ballast chamber for sinking. This bottom flares downward from the inner to the outer wall, the voids between the timbers being well packed in with gravel and stone chips to solidify the mass and gain sinking weight. The outer walls are 23 feet deep, while the inner walls finish off on top, 4 feet less. The curbs are strengthened and stayed by transverse partition walls, forming interior cells, in which the piling is driven. The curb for Pier III. is 71 feet square, with 16 interior cells 12 feet square, while the curbs for Piers II. and IV. are 50x80 exterior dimensions, with 8 cells 15 feet square.

As these curbs would finish at or below the river bottom, for the convenience of their handling and control, as a guide for the piling operations and regulation of the masonry caissons, a stout and well-braced temporary framework was carried up from the partition points of the inner and outer walls, to finish about one foot above high water, when the curbs were settled in place. One side of this framework was kept down sufficiently low to take the draught of the masonry caissons. Some little anxiety was had regarding the control of these curbs during sinking, as to place and level, since the leeway or clearance for the succeeding work was not over 3 feet in any direction, and a comparatively small difference of level at the bottom would have a very marked effect upon the verticality of such a great depth of framework at the surface of the water. This sinking was performed, however, with great success, with the aid of the pile-driving machines and falls attached to the fenders, occupying but a few hours for either curb. So soon as the curbs were settled in place, the pockets were filled with ballast sufficiently to hold them against any possible displacement, and so distributed as to correct irregularities of level as much as possible.

Piling.—The piles used were Michigan white pine and Southern yellow pine, as straight as it was possible to get them, and from 85 to 95 feet long. They held their size remarkably well, few measuring less than 9 inches at the point, and were 15 to 20 inches when cut off. The pile-driving scow used was 23 feet by 48 feet, with 70 feet leaders, and a 4,000-pound hammer run by a double drum Mundy 30 horse-power engine, with 10x16 cylinders. The first curb ready to receive the piling was that for Pier III. (center pier), in which piling was commenced August 27. This curb was to contain 640 piles, or 40 piles to a cell. Long as the piles were, when driven they would be from 30 to 40 feet below water, which involved the use of some kind of follower arrangement.

After several trials with ordinary socket connections between follower and pile, it was found impossible to keep from smashing the sockets, and before resorting to a more complicated system of following, a trial was made with a simple ringed oak follower, 10 inches square, with a 2-inch dowel in the end. This method proved so successful that it was adopted and carried out through the rest of the work. It was found that by carefully steadying the machine, holding the follower firm in the leaders and keeping it plumb, the descent of the pile was conveniently controlled under the *short*, quick blows of the hammer. The method adopted for the above foundation was to plant all the piles (excepting in one cell, left for introducing the saw), and then drive them to bearing. There was just hold enough in the bottom to support the piles, leaving their heads above, or even with, the water. The planting and driving of these piles occupied about 20 days, barring one cell of 40 piles, which had to await the cutting off of the piles driven, after which this vacant cell was filled and cut.

As no sawing was ever performed in such deep water (from 47 to 51 feet according to stage of tide), the commencement of that operation was awaited with no little anxiety, not only as to the operation itself, but also maintaining a reasonable level plane of cut off, under the swells produced by tide and wind, at times quite heavy. The vertical saw shaft of 3-inch steel, was solidly backed by two 14x14 yellow pine timbers, well bolted together, to within 8 feet of the saw. This back-bearing timber was slung in the leaders of the pile-driver and hoisted up and down, according to the stage of the tide. The saws were 50 inches in diameter, three-eighths of an inch thick, with the usual teeth.

The driving pulley attached to upper end of shaft was 15 inches in diameter, and was driven direct from a 48-inch pulley on the engine shaft through a 10-inch belt. The shaft was run at a speed of about 400 revolutions. It was soon demonstrated that there would be no difficulty cutting off the piles, but it was also demonstrated that hunting up the piles to cut, with no visible guide to locate them, was quite a different matter. The saw would get started into two or more at a time, and the shaft would jam against the upper part of the pile. Backing out was not always an easy thing to do among piles so thickly driven, and the breaking of saws was becoming a serious annoyance. Resort was had to divers, two being constantly at work in alternate shifts. Their mission was to go down and locate the piles in reference to position of saw, attach a line to each pile that was to be sawed, come up and report direction in which to move the machine. After a little experience, piles began to come up with a reasonable speed, as high as 34 being cut off in one day (which was the exception), some days none, when the saw would get jammed, with resulting trouble and delay. Keeping the cut-off level was an exceedingly troublesome matter—there was no way of sighting from shore, the distance was too great, besides the shifting of the machine in every direction would be continually cutting off the view of the shaft. A level board was therefore attached to one side of the temporary framework that had been carried up from the curbs, with a mate on the opposite side, across which the ring on the shaft was sighted. By this method the piles were eventually cut off. As many of the yellow pine pile tops sank when cut, it was difficult to tell whether any had been missed, and the machine was passed back and forth in two directions, at right angles, shifting two feet each time.

The experience gained in the piling for foundation of Pier III. suggested certain modifications of procedure for Piers II. and IV., the building of their curbs, and their placing, being carried on during the piling operations at Pier III. Each of these piers were to have 368 piles, those for Pier II. being cut off 60 feet below high tide, and those for Pier IV. 43 feet below. This last pier followed the center pier, and instead of filling all the cells before cutting, the piles were planted and driven in rows lengthwise with the curb, commencing at one side, each row being cut off as soon as driven before another row was started. To each pile was attached a line, which was fastened to a guide timber stretching from end to end of the curb and resting on the framework. This timber was shifted as each successive row was completed. It was found that by starting the saw at one end of the row and following the line as indicated by the attached cords, the work could be rapidly and continuously performed without the aid of divers, and none were again employed throughout the remainder of the piling. The leveling was sighted from carefully placed sight-boards fastened to the fenders outside the curb at either end, having a long slit one-eighth of an inch in width. The observer, standing on the fenders, could comfortably and with great accuracy keep the elevation ring on the saw shaft always in exact line, as was proved by the perfect level to which the masonry platforms settled for these two piers. The sawing off the piles at 60 feet was as readily performed as at 43 feet.

Sand Filling.—As the foundation piles for each pier were finished, the whole interior of the curbs and ballast chambers were filled with bank sand in which more or less gravel was intermixed. This filling was at first spouted in through 9-inch tubes reaching nearly to river bottom, but they were soon abandoned for the more expeditious method of shoveling the sand overboard, the current being too sluggish to carry it off from where it belonged, care being exercised to unload at either end, as the tide ebbed or flowed. After the above interior filling, the space between the dredged excavation and the sides of the curb were likewise filled, partly with sand and partly with material dumped from scows brought down from the upper river, where the channel was being deepened by the Government. After the piers were built, this sand filling was carried five to ten feet up the sides of the masonry platforms, covering the outer walls of the curbs, and which the current is too feeble to scour or displace.

The Caissons.—During the progress of the foundation work the caissons were being prepared. The caissons for Pier III. were 50 feet square and 50 feet deep, while for Piers II. and IV. they were 30x60 feet square, and 59 feet and 45 feet deep, respectively. The depth of the platforms or bottoms of the boxes were regulated by the maximum it was deemed desirable to load the piles—viz., ten tons each, and by the practicable height of sides over which to hoist the heavy ashlar stones, many of four and five tons weight, which was fixed at 35 feet. Even with this height of sides it was found convenient to have a door in the upper portion of one of the sides for about one-third of its descent. It would be a great convenience to build the sides of such deep caissons in two stories, erecting the second after the first had been sunk to within five or more feet of the top. These platforms were composed of 12-inch square hemlock timbers, laid in transverse courses. They were started on launching ways, until four courses were put together, when they were launched and finished afloat. The courses were securely drift-bolted together with ⅞ square by 20-inch bolts, particularly around the sides, for four courses in, where every timber was bolted to each alternate under timber. The final course of the platform, on which the masonry was to be started, consisted of a 6-inch calking deck of creosoted Carolina pine, very thoroughly spiked with 12x⅝-inch spikes, special care being given to the portion extending beyond the masonry. This deck was laid in Portland cement mortar, spread over the preceding course, which, in turn, was well calked with cotton yarn, which swells when wet. The finishing deck was calked with oakum. The squared-up ends and sides of the platform were cased in with two courses of 2 inch creosoted plank, breaking joint with each other, and secured in place with 6x⅜-inch ship metal spikes.

The caisson sides were very stoutly built, as they might be subject to very rough handling during process of sinking. All these caissons proved exceedingly tight, only a little leakage taking place through an occasional sun crack in the siding or a loose knot.

The class of masonry adopted is quarry faced Ashlar in 2-feet courses for all face work, the hearting being concrete well rammed in place, except for the abutments, where rough backing was used, with concrete rammed in all voids. The concrete was made from coarse beach pebbles, beach sand, with Burram Portland cement below water, and improved Union cement above. Two barrels of cement and six barrels of sand being used for each yard of gravel, with an additional half barrel of cement for concrete deposited under water. Mixtures were made in 2-yard batches, gauged by a frame on deck of the concrete scow, all mixing being performed by hand. The moisture was regulated with careful supervision, and applied by sprinkling pots so that the mortar should be thoroughly damp without being wet. The pebbles were all wetted before applying the sand and cement previously mixed dry. The weight of the concrete so made was 135 pounds per cubic foot, and the solid piers averaged below water 150 pounds per cubic foot, deduced from the flotation of the caissons.

SUPERSTRUCTURE.

The superstructure, built for double tracks, is of the American type pin connection work, intended to cover the best results of modern practice, built wholly of steel, excepting lateral rods and a few minor parts, which are of wrought iron. It consists of two deck spans of 150 feet, and two fixed spans of 310 feet, symmetrically disposed on either side of the great swing draw span of 503 feet in length, forming the central feature of the work. The deck spans of three trusses, 20 feet deep and 9 feet centers (so spaced that the tracks on 12 feet centers will bring an equal load on each truss), are designed on the triangular system. The through fixed spans consist of two trusses on the Whipple system, 28 feet 4 inches centers. The swing span, with the same depth of truss at the ends as the adjacent fixed spans, slopes upwards towards the center where it attains a height of 71 feet, two-fifths the slope on either side of center being in a parabolic curve, the balance being a straight incline. The loads for which all the spans were proportioned, in addition to their own weight, consisted for each track of two consolidated engines with tenders covering a space of 103 feet, and weighing 171 tons, followed by train assumed to weigh 3,000 pounds per foot.

The steam power of the draw span consists of a pair of oscillating cylinders, 10 inches in diameter, with 7-inch stroke, setting at an angle of 120 degrees and working upon one crank shaft, running at a maximum velocity of 200 revolutions (averaging about 170), applying the power through two Frisbie friction clutches, the one driving the unlocking shaft, the other the turning shaft. The turning shaft, of $4\frac{7}{16}$ inches diameter, runs at a speed of nine turns per minute, gearing direct through a pair of beveled gears into the vertical drum shafts. The unlocking and rail lifting shaft is three inches in diameter, speeding 60 revolutions per minute, and gears by transverse shafting at the bridge ends into the pedestal feet, screwing up and down in the hub of a beveled gear wheel, forming a fixed nut. The minimum time of operating the draw is fifteen seconds for lifting rails and raising end screws, and two and a half minutes to open, which is varied at will of operator, more time being consumed in starting and slowing up in high winds.

The signaling mechanism of the bridge, devised by the Union Switch and Signal Company, is governed from a cabin erected in the bridge tower, and is an interlocking system, with electric safeguards which prevent the movement of the switches or signals after a train has entered the section protected.

The steel used is low grade or soft steel, that is, a metal not running over 65,000 to 68,000 pounds per square inch breaking strength. In the draw span the Bessemer was confined to the vertical and inclined posts at center and center section of bottom chord. Open hearth steel was preferred on account of the process insuring a uniform product and the control of its composition.

Protection fenders are built around Piers II., III. and IV., with flaring wings and pointed ends. Those for the rest piers are 180 feet long, while that for the draw pier is 570 feet long. They consist of a system of piling and framework of yellow pine timber, sheeted vertically with 4 and 6 inch plank, corners being protected with boiler-plate armatures.

The disbursements made in execution of this work, up to subgrade and laying of track, when the work was handed over to the regular organization of the company, amounted to $1,293,939.90.

On the completion of the bridge, the following test was made under the direction of Mr. E. P. Dawley, Chief Engineer of the N. Y. P. & B. R. R., which, although below the basis of the design, employed all the available engines that could be spared for the purpose. Two trains were made up on the east side of the river and driven over the structure side by side. That on the west-bound track was composed of three engines in a space of 150 feet, and weighing 235 tons, followed by 155 feet of loaded passenger cars, weighing 59½ tons, or a total of 294½ tons in 305 feet. That on the east-bound track was composed of three engines, weighing 221 tons in 160 feet, followed by 330 feet of passenger cars, weighing 139 tons, or a total of 360 tons in 490 feet—of the passenger car load 150 feet weighed 59½ tons, or same as on west-bound track. For both tracks, the total load with 150 feet of cars, was therefore 575 tons, in a space covering a 310-feet span—the engines on the two tracks being *vis-à-vis* with each other, as near as practicable. The greatest deflections recorded were as follows:

	N. Truss.	S. Truss.	
Easterly 310′ span.....	2⅜"	2¼"	Recovery perfect.
East arm draw, 240′ ..	1⅝"	2¼"	" "
West arm draw, 240′...	1¼"	1⅜"	Recovery perfect. less ⅛" for S. Truss.
Westerly 310′ span....	2⅜"	2¼"	Recovery perfect, less ⅛" for N. Truss.

The easterly 148-foot deck span deflected $\frac{11}{16}$ inch and the westerly deck span 1 inch.

The maximum raise of unloaded draw arm was 2½ inches—the opposite arm being loaded with six engines, with about 90 feet of cars. The 160-feet two truss through span on the west approach over the New London northern tracks—deflected 1⅛ inches for north truss, and 1 inch for south truss, with complete recovery, lacking $\frac{1}{16}$ inch for north truss.

The bridge was open to travel, with imposing ceremonies, on October 10, 1889, 16 months after the commencement of the work.

TESTS OF WATER AND OTHER PIPES.

IN discussing a paper by Mr. T. W. Yardley, on "Specifications for Cast Iron, Coated Water Pipe," read several months ago, before the American Institute of Mining Engineers, and presented also at the Chicago meeting, last May, of the American Water-Works Association,* Mr. James C. Bayles said:

"I should in every case demand that the pipe be tested before it is coated. This is especially true of cast iron. Any form of coating suitable for a pipe which is to be shipped and handled will conceal a multitude of small defects in casting, such as blow holes, sand holes, and even small shrinkage cracks. In 1887 the Commissioners of the Health Department of New York City found it necessary, in the discharge of their responsibilities relative to the plumbing of new buildings, to amend the plumbing code by the insertion of a clause forbidding the use of dipped, varnished or painted pipes. The reason for this action was the discovery that even a thin coating, of very little value as a protection for the iron, could be made to conceal so many foundry defects, and permitted so much carelessness on the part of makers, that sound pipes were the exception rather than the rule. The value of such a coating in enabling pipes to pass a test is shown in much of the light riveted pipe in the market. I have seen a pipe put together with small, cold rivets, headed by pressure, which, after coating with coal tar and asphalt, has shown in the testing machine a capacity to carry without leaks a test pressure much higher than Mr. Yardley prescribes for the strongest and heaviest cast-iron pipes he mentions † Before coating, the seam would have shown a continuous leak from end to end. The fact that a coated pipe will hold water under a considerable pressure in the testing machine seems to me to speak more for the coating than for the pipe. A cork inserted in the end of a gun barrel will usually be found in place when the explosion of the charge has burst the barrel. Experiments show that a plug of mud, or even of snow, will do the same. As a manufacturer of pipes, I should be very much pleased to have consumers specify that none should be tested until they had been coated. We should have very few wasted. For cast-iron pipes the test pressures prescribed by Mr. Yardley seem to me much higher than is necessary. The calked joint is not adapted for high pressures, and cast-iron pipe is seldom employed under pressure greater than a lead calking will stand. It is not unusual in water-works practice for the lead to blow out of pipe joints at pressures much below those which the pipe will carry safely and comfortably. This is especially true if opportunity is offered for such changes of temperature as will produce a measurable contraction and expansion with the changes of the seasons. The strength of the pipe cannot be greater than the strength of its joints, and with the hub and spigot connection the usefulness of cast-iron pipes as a pressure conduit has well defined limitations. In buying it for any purpose for which that kind of pipe is adapted, I should be content with half the test pressures prescribed by Mr. Yardley, but should insist on having the test made before the pipe was dipped — and, for that matter, I should require a very much better coating, after testing, than a coal pitch varnish applied at 300° Fahr."

Replying to the above, Mr. Yardley said:

"Cast-iron pipes for water-works were first used by the New River Water-Works Company, of London, England, in the year 1810. In 1822 the greatly increased demand for water made it necessary for the company to enlarge the mains. In taking up some of the pipe laid in 1810, many were found rusted so much that they were unfit for future use. This fact coming to the notice of Dr. Angus Smith, he commenced a series of experiments in the preparation of a coating of varnish to be applied to the inner and outer surfaces of pipe to be used for carrying water. His experiments demonstrated the fact that his varnish would not stop the rust when it had once commenced, notwithstanding the rust was covered by the varnish. It was then he adopted the system of coating pipe as soon after cleaning as was practicable, and requiring the pipe to be heated to 300° Fahr. before immersing it in the bath.

"In 1858, some of the pipe being taken from the trenches in which they had been underground for 30 years, the varnish was found hard and bright, and the pipes that were broken gave no sign of rust. So satisfactory was this result that the English Government gave a patent therefor to Angus Smith, and his process has since been used by all makers of cast-iron pipe for water-works. In making my specifications I have followed what I believe to be the recognized practice of the best hydraulic engineers of this country, and I know I have the indorsement of many. I was not aware until Mr. Bayles made the statement that tar coating possessed so much strength. If he is correct, would it not be more economical for water-works companies to have the iron shell of the pipe much thinner than now used and give the pipe greater thickness of tar? In regard to the hydraulic test, I have the best authority for the pressure required for all pipe above 16 inches diameter. The increased pressure is specified for the smaller diameters, because the water test is the only one used. It would be very inconvenient, as well as quite expensive, for the makers if they were required to take test bars for so great a number of pipes as the foundry could turn out daily of the smaller size."

THE WATER SUPPLY OF PALERMO, SICILY.

THE sources of the water supply of Palermo, Sicily, and the methods of water distribution are described in a report of the British Consul at that city.

It appears that the deficiency of the supply, especially in summer, has long been one of the great grievances of the Palermo householders. The supply at present is meted out in *penne*—that is, "quills"—of water, a *penna* being a continuous supply of as much water as will run through a pipe of the size of a goose quill. There are houses of three stories in Palermo, inhabited by three or four families, which have no more than a supply of one *penna* of water per day, and even this at times is intermittent, for the men who have the care of the water pipes contrive, when water is required irrigating orange and lemon trees and melons to divert, for a consideration, the water from its proper destination.

The water with which Palermo is mainly supplied comes from the hills near Montreale. The distributing system is very curious and is said to come down from the days of the Arabs. Visitors making excursions in the environs are often puzzled by the appearance along the roads of strange structures in the form of lofty, truncated obelisks. These are called water towers, and some of them are very ancient, built of stone and overgrown with ivy. There is usually an iron ladder reaching half way down, by which the watermen, who carry ladders to be joined to them, can get to the tops. On the top of each tower is a small reservoir into which the water rises, due to its head. From the reservoir the water is distributed in pipes to the neighborhood.

In view of the scarcity of the supply the formation of an Anglo-Palermian company to bring water from a copious source at Scillato, about 20 miles off, has been greeted with much satisfaction.

IRRIGATING DUTY OF WATER.

FROM a paper read before the Denver Society of Engineers, by Mr. G. C. Anderson, it would appear that the irrigating duty of water varies considerably. In Spain the duty is 35 acres per cubic foot per second in Valentia, for rice cultivation, or 101 acres per cubic foot per second for general crops. In Granada it was 286 acres per cubic foot per second. In Elche and Lorca the duties reach as much as 1,072 and 2,200 acres per cubic foot per second. In India a duty of 240 acres was obtained on the Ganges Canal, whilst one of 250 acres has been reached on the Eastern Jumna Canal. In the older canals of California a duty of 555 acres has been reached, but this has now been increased to at least 1,000 acres.

THE new Pennsylvania Railroad passenger station at Jersey City, N. J., will have an iron arched roof like the Grand Central station at New York, but larger. It will be 256 feet wide along the water front, and 600 feet long. This is exclusive of the waiting-room and ferry accommodations.

A 300-FOOT span suspension bridge at San Bernandino, Cal., gave way about two weeks ago, on the application of a test load. The bridge had been pronounced unsafe by several engineers.

---

[*] See THE ENGINEERING AND BUILDING RECORD, July 19, 1890.

[†] Mr. Yardley prescribed from 450 pounds hydrostatic pressure per square inch for 6 and 8-inch pipe, to 250 pounds pressure for 36-inch pipe, and upwards.

THE NEW LONDON, CONN., WATER-WORKS HIGH SERVICE.

THE original water supply of New London, Conn., was by a gravity system. Recently a portion of the water from these low pressure mains has been diverted to a high service system, in which the water is elevated to a tank, and thence supplied to the distribution mains at a pressure about 15 pounds greater than that of the gravity mains.

The delivery of water through the gravity main is made to operate a motor, driving a pump that fills the high service tank. In case of insufficient supply from the high service system, water is admitted through a 12-inch check-valve from the low pressure system.

Figure 1 is a perspective of the motor and pump; Fig. 2 is a plan of the same; Fig. 3 is a vertical elevation corresponding to Fig. 2, and Fig. 4 is a horizontal section through the motor.

The motor A is situated on the line of the 20 inch supply main and about 500 feet from the tower. It consists of a cast-iron cylinder C, 36 inches in diameter and 8 feet long, set at right angles to the line of the main, containing a hollow, air-tight, steel plunger, 24 inches in diameter and 54 inches long, which makes a 36-inch stroke.

On each side of the cylinder are two 24-inch butterfly valves E E, etc., which are connected by means of reducing Y's and 20-inch bends with upright 20-inch Y branches set in the supply main. The pump F is situated at the end of the main cylinder, the pump plunger being on the same rod as the motor plunger D. The stems H H, etc., of the butterfly valves run up through the casing and are connected by means of arms I I, etc., and rods J J, etc., with a wrist plate K on the center of the motor cylinder.

On top of the main cylinder is an auxiliary cylinder L, 6 inches in diameter, taking water through a cylindrical slide valve. On the piston rod M of the auxiliary cylinder is a piston working in an air cylinder N, 10 inches in diameter, which acts as a cushion for the valves. This piston rod is connected with the wrist plate above mentioned. The auxiliary cylinder is actuated by water passing from the low-service main and exhausting into the air, or may, when the tank is full, take water from the high-service pipe and exhaust into the low-service mains. In the first instance the amount of water wasted is 1⅛ gallons per stroke; in the latter case no water is wasted.

The supply main runs under the motor making a by-pass. In the by-pass is a 20-inch check valve which closes by means of a lever, which is weighted so as to offer a resistance of about five pounds per square inch.

The pump is the usual horizontal plunger pattern, with rubber disk valves and air chamber. The pump plunger makes the same stroke as the motor plunger, and is 8 inches in diameter.

The action of the motor is as follows: The water passing to the low-service district is deflected by means of the check valve into the motor, passing through one of the butterfly valves, one on each side being open. The water drives the motor plunger over, which, when near the end of the stroke, moves a tappet, which latter reverses the valve on the auxiliary cylinder. The action of the auxiliary piston reverses the butterfly valves, opening two and shutting two, by this means deflecting the water to the other side of the motor plunger, which reverses the above operation; the water, after driving over the plunger, passing on to be used in the low-service district.

The wearing surfaces of the butterfly valves and the connecting rods are of phosphor bronze, and all parts of the machine are made of the strongest and most durable material. Provision is made for substituting larger motor or pump plungers, if desirable, at small cost, without other changes in the machine, and two-geared 20-inch gates are set to shut the motor out of the system. The present pump delivers 7¾ gallons per stroke, against a pressure of 15 to 20 pounds per square inch, with a loss of from two to three pounds per square inch on the low-service, depending on the velocity.

The motor was built by W. H. Lang, Goodhue & Co., of Burlington, Vt., from designs by W. H. Lang, of that city.

The motor is covered by a brick building 24x38 feet inside. The wall from the floor to the level of the ground, a distance of 5 feet, is 20 inches thick, of heavy stone masonry. This wall is capped by a granite water table on which rests the brick walls, 14 inches thick, including a 2-inch air space. The brick walls terminate 11 feet above

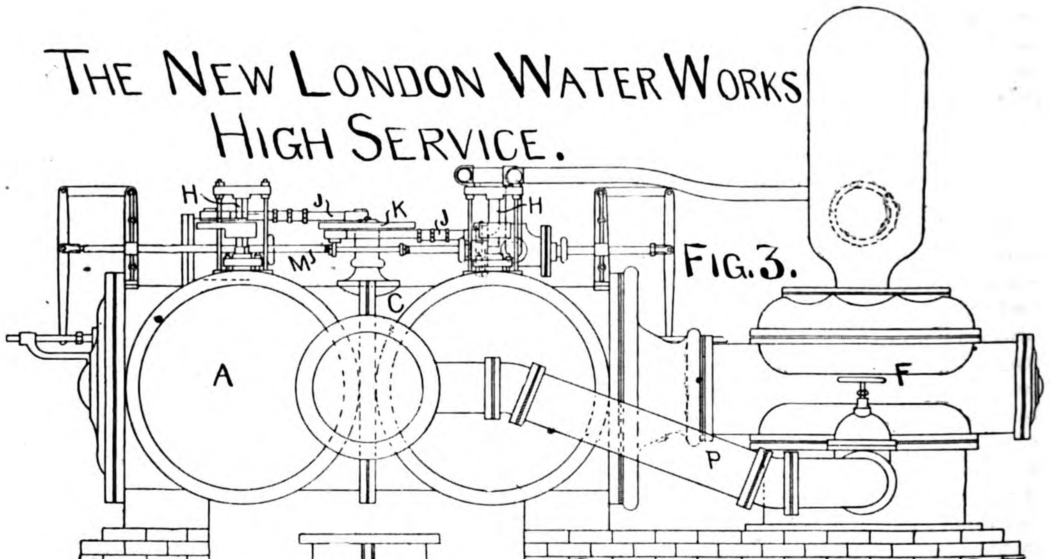

Fig. 3.

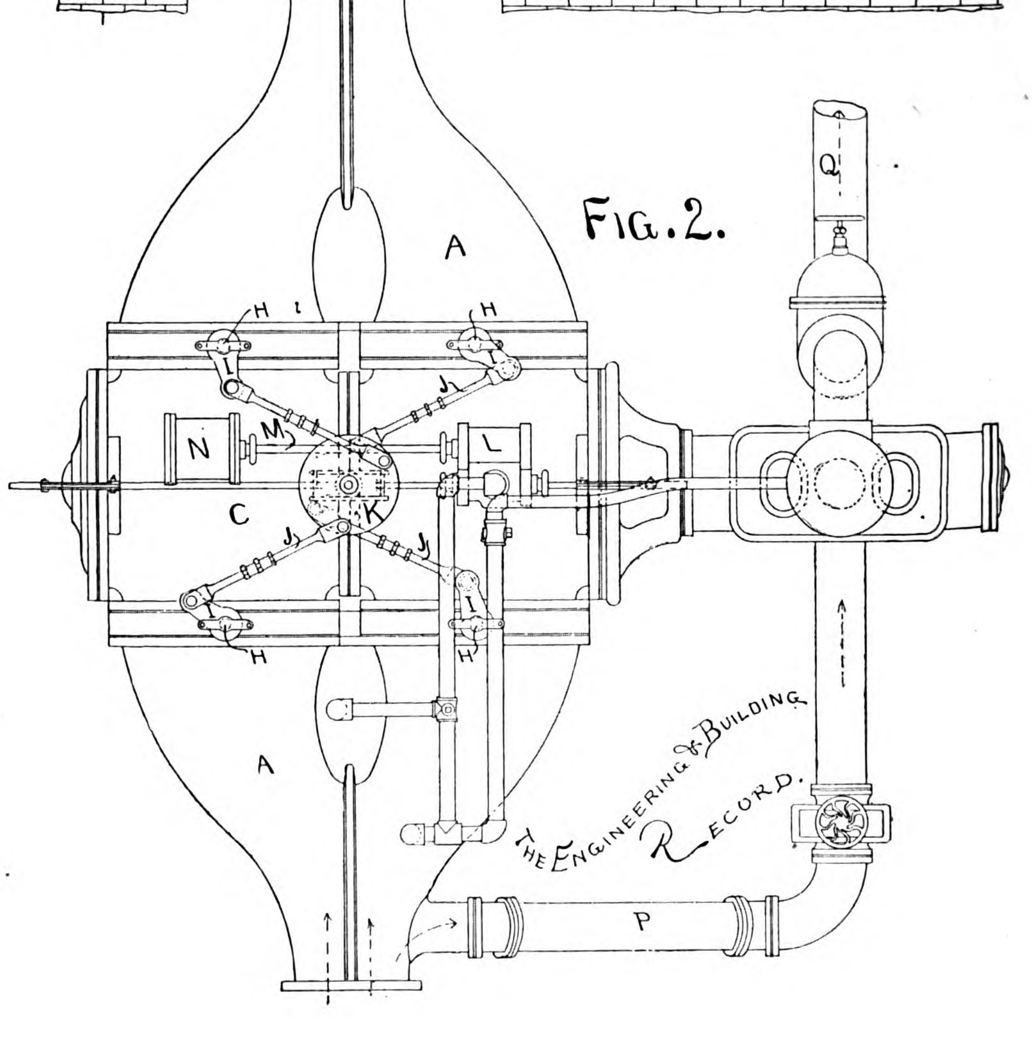

Fig. 2.

the ground, and are surmounted with a trussed roof, covered with slate. The windows are furnished with double sashes, and the doors are of 2-inch cypress. The whole is especially designed to exclude the cold and prevent freezing.

The foundation for the motor house, and also for the tower was built by George Prest; the brickwork by C. P Smith & Co., and the woodwork by A. O. Goddard, of New London. The grading, pipe connections, and concrete floor was done by day work by regular employees of the water works department.

The tower, which is situated on a hill about 120 feet above mean high tide, rests upon four heavy granite masonry piers laid up in cement mortar. These piers are surmounted by pillar blocks of cut stone, 10 inches thick. The piers rest on a clayey hard-pan formation. Two 1½-inch bolts run from the bottom to the top stone, and the iron bed plates are secured to the pillar blocks by four 1-inch bolts running through this stone, the whole structure being thus fastened together.

The tower (Fig. 5) consists of four wrought-iron lattice posts, resting on wrought-iron bed plates which support nine plate girders, four feet in depth. The tower is surmounted by a wrought-iron tank weighing 38,000 pounds, and built up of plates of the following thicknesses: Bottom, ½-inch; first plate, ⅜-inch; second plate, 5/16-inch, and third, fourth and fifth plates, ¼-inch. The vertical seams are double riveted, and the bottom and horizontal single riveted, with ¾-inch and ⅝-inch rivets. A 4x4-inch angle iron is riveted at the bottom, and a 4x3-inch T-iron near the top. Oak plank hewed to fit the laps are placed between the tank and the girders. All the iron used in the structure is of 45,000 pounds tensile strength. A suitable iron ladder runs from the ground to the top of the tank, and the tank is provided with a manhole near the bottom. The supply pipes are of spiral welded steel; these pipes extend up through the bottom of the tank, the supply pipe to within 4 feet, and the overflow to within 1½ feet of the top of the tank. Where these pipes are fastened to the tank, corrugated copper expansion joints are inserted. The water enters the tank near the top and, by means of a check valve, is drawn from near the bottom. All the ironwork is thoroughly painted. The capacity of the tank is 90,100 gallons.

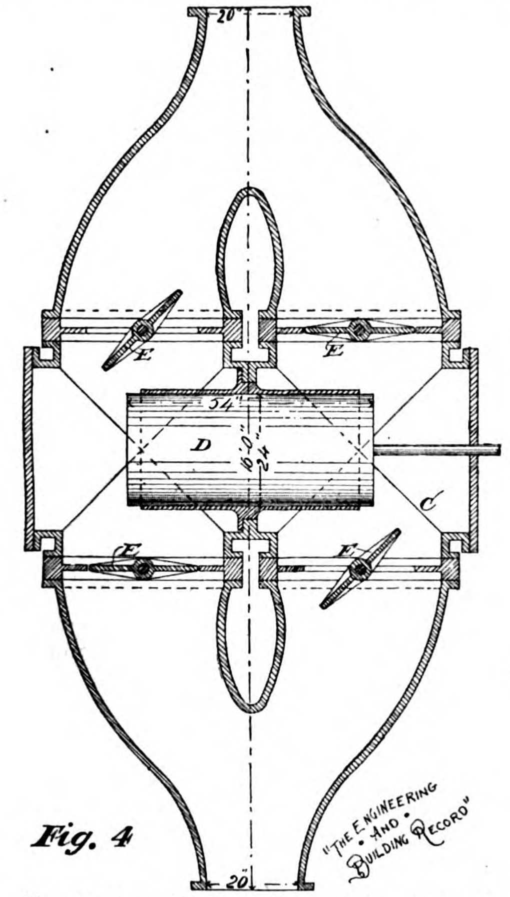

Fig. 4

New London Water Works High Service

The tower and tank were built by the Berlin Iron Bridge Company, of East Berlin, Conn. Chief Engineer W. H Richards acknowledges valuable suggestions regarding the construction of the motor and tank from W. B. Sherman, C. E., Providence, R. I., and commends the efficient work of his principal assistant engineers—G. K. Crandall, in charge of original surveys; G. E. Manning, in charge of pipe inspection and high service, and G. H. Chase, in charge of pipe laying.

AN IMPORTANT NATURAL GAS DECISION.

Judge Lemmon, in the Common-Pleas Court, at Toledo, O., on September 29, rendered a natural gas decision of importance.

The Northwestern Natural Gas Company, which is controlled by the Standard Oil Company, obtained a franchise to lay pipes to furnish natural gas to citizens in the fall of 1886 by ordinance of the City Council, in which certain rates were fixed, to be binding until July 1 last; and it was provided that future rates should be fixed by agreement between the city and the gas company. In March, 1887, the Ohio Legislature passed an act empowering City Councils to fix the price of natural gas to consumers. On August 4, 1890, the City Council by ordinance fixed the price at a rate the gas company refused to accept. The city solicitor then obtained a temporary injunction, restraining the company from furnishing gas at any higher rates than the ordinance permitted, and applied for mandatory injunction to compel them to furnish gas at ordinance rates.

The case was argued at length, and Judge Lemmon decided against the city on the ground that the original ordinance of 1886 and its acceptance by the company was of the nature of a contract, and the subsequent law could not impair the obligation of that contract under the federal constitution, and that if the rates are deemed too high a court must pass upon the question, and not the City Council.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

LIME *VS.* CEMENT MORTAR.

Chicago, September 29, 1890.

To the Editor of The Engineering and Building Record:

Sir: Your extracts from Prof. Ira O. Baker's paper on "Lime *vs.* Cement Mortar," in your issue of September 27, are interesting and valuable in strengthening opinion as to the quality of mortar which it is advisable to use in heavy buildings. Portland cement enters each day to a greater degree into the construction of tall buildings in this city, and its use will undoubtedly continue to increase. I desire, however, to enter a protest against the arbitrary, and I believe, incorrect change in the nomenclature of cements which Professor Baker suggests, or rather, asserts.

By long custom the name Portland cement has come to mean any artificial cement, and is firmly fixed in this meaning in literature and in the minds of engineers. In distinction from this the cements made from rocks, into which enter proportions of lime and clay, producing, in varying degrees, hydraulicity, are called "Natural," "American," "Domestic," and "Roman," as Professor Baker tells us. Professor Baker further tells us that these names are inappropriate, and that they should all be classed as "Rosendale Cement." To my mind, the most appropriate name for a class of cements, the material for which is found in nature ready for manufacture, is "Natural Cements." Further, it would be entirely inappropriate and very confusing to apply to a class of cements, varying through a wide range of hydraulicity and activity, the name of one individual of this class which is, at present, on the market. Such action would lead to endless differences in the interpretation of specifications or would require explicit and lengthy explanation.

This confusion or want of meaning is evident further on in Professor Baker's paper, when he states: "If great ultimate strength is required, then Portland cement must be employed; but if a quick-setting mortar is desired then Rosendale cement must be employed." There is absolutely no such distinction between Portland and natural cements. Greater strength, more even quality and resistance to heat are the distinguishing characteristics of Portland cement mortars. Quickness of setting or activity in any degree is not peculiar to Portland cement, for while in general Portland cement is considered slow-setting, yet the variation is great, depending in part on the freshness of the cement, and it is possible to obtain Portland cement of any desired degree of activity. Nor is activity a distinguishing mark of natural cements, varying in these as it does with freshness or the qualities of the rock. When Professor Baker says, "Rosendale must be employed," does he mean the North River cements, which vary somewhat in activity, or Akron, which must be quicky used, or Utica, which may lie for hours in the box without suffering in ultimate strength? In the light of his first quoted statement he means natural cement mortar; yet see how this varies.

If it were at all desirable to give this class of cements a proper name, "Roman" or "Boulogne" cement would be preferable to "Rosendale," as these names, so far as I know, are no longer used as brands for any cement in the market; but I think that all engineers will agree with me that the term "Natural Cement" conveys the idea clearly as to what cement is desired, and in conjunction with the local name or brand, fixes the quality it is deemed preferable to use.

Wm. S. Mac Harg.

ECONOMICAL FREIGHT TRANSPORTATION.

In his book on famines in India, the late Mr. Thomas, according to London *Engineering*, says: "Perhaps the most economical application of power in the conveyance of goods in the world is that which is to be seen in the canals of Malabar. There a tree, 60 feet long and 2½ feet in diameter, is hollowed into a canoe; the opening above is not wider than a plank would cover. This canoe will carry with ease five tons of grain. It floats on the water like a duck, requires little depth and little width. A boy sits at the helm steering and a man propels it by walking along the plank with a punting pole against his chest. This man and boy take this boat, containing 12 ordinary cart loads of grain, 30 miles in the 24 hours, thus for six annas—9*d.*—doing three days' work of 12 carts with their pairs of bullocks and of their drivers."

At Gothenburg, in Sweden, a number of experimental borings have been undertaken with a view to increase the water supply of the town. The result has, as a rule, been favorable; the water-carrying strata has been met with at a depth of about 100 feet. They consist of sand and gravel, and have in some places reached a depth of some 230 feet, but as a rule rock is met with at a depth of from 125 feet to 150 feet. The water rises in a pipe to about 20 feet, and the temperature is 9° Celsius (48.2° Fahr.)

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department*. Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

MAKERS OF WROUGHT-IRON, CEMENT-LINED PIPE.

THE Connecticut Pipe Manufacturing Company, of New Haven, Conn., write:

"We notice in your issue of September 20, an inquiry from Thomas J. Callahan, of Renovo, Pa., who wishes to know parties manufacturing wrought-iron, cement-lined pipe.

"It is our pleasure to inform you that we are very busy with all sizes of pipe up to 27 inches in diameter, and that we manufacture this pipe of the best wrought iron and pure cement only. Our improvements and success with composite underground conduits has been an inducement to the following parties to manufacture under our patents:

"The Penn Pipe Manufacturing Company, Germantown Junction, Philadelphia; the New York Pipe Manufacturing Company, Hastings on the Hudson, N. Y.; the Illinois Pipe Manufacturing Company, Peru, Ill., and the U. S. Construction and Pipe Manufacturing Company, San Francisco, Cal."

DELTA METAL.

ACCORDING to *Glaser's Annalen*, Delta metal, to which so much prominence has been given in the last few years, is a very old alloy, having been known to the old Egyptians. It was first prepared, however, in a scientific manner by Alexander Dick, a German, in 1882. This metal is an alloy of copper, iron and zinc, resembling aich-metal and sterro-metal, which contain the same elements, and are largely used for heavy guns. The Delta metal is prepared by taking advantage of the fact that melted zinc will dissolve about 9 per cent. of its weight of iron. The saturation point of the zinc depends upon the temperature of the metals during the process—the higher the temperature the greater the amount of iron absorbed. At a white heat nearly 20 per cent. is taken up. The fluid alloy is then mixed with an amount of copper or copper and tin, which varies according to the purpose for which the metal is intended. The oxides present are removed by the addition of a small quantity of manganese, usually in the form of copper manganese alloy.

MINNEAPOLIS, Minn., is now expending $150,000 in the first experiment in paving its streets with Trinidad asphalt.

ELECTRIC MOTORS.

(Continued from page 283.)

THE "C. & C." MOTOR.

The "C. & C." Electric Motor Company, 402-404 Greenwich Street, New York, makes the motor of corresponding name, shown in Figs. 4, 5 and 6. Figure 4 represents the standard form of the motor of three horse-power, Fig. 5 shows it connected to a Lidgerwood hoist, and Fig. 6 shows it in combination with a 30-inch Blackman ventilating fan. For small organs, and where light power is required, a motor and 4-cell battery outfit has been used.

The lower pole pieces of the "C. & C." motor are cast in one piece with the bed, the upper one being a separate block. To these pole pieces are bolted the field magnet cores. The latter are of forged wrought iron, shaped like segments of a circle. This form of magnet construction is claimed to give the shortest possible magnetic circuits, and to thereby reduce the quantity of iron used and the power required to excite the magnets. The motor is a very compact machine requiring but little space. An improved Siemens winding is used, and the armature and commutator are divided into more than the usual number of sections, thereby, it is claimed, diminishing the danger of short circuits in the commutator. The bearings are self-aligning, so that they cannot bind, allowing the armature to be taken out and replaced without trouble. The wearing parts are of hard cast bronze. An improved adjustable feed oil-cup is used. The brush holders are supported on brass rods attached to a rocker arm, which may be tightened or loosened at will. The pressure of the brushes may be adjusted by a slight movement of a single nut. The machine stands on a stout hard wood base provided with three slotted tracks on which the motor can be moved laterally by means of a hand-wheel. The motors are made for both arc and incandescent circuits, and range from ⅛ H. P. to 40 H. P.

In addition to what we have here illustrated, the "C. & C." Motor Company turn out a number of other special motor combinations, among them smaller fan outfits than the one shown in Fig. 6, and blower combinations. The latter were first constructed for ventilating engine and boiler rooms on board ship, and have been supplied to the U. S. cruisers "Baltimore," "Charleston," "San Francisco," "Philadelphia," and "Petrel," where they are reported to have thus far given entire satisfaction.

FIG. 6.—MOTOR AND FAN COMBINATION.

THE "C. & C." MOTOR, MADE BY THE "C. & C." ELECTRIC MOTOR COMPANY, NEW YORK.

Eight sizes of these blower combinations are made, the capacity of the blowers ranging from 450 to 4,840 cubic feet of air per minute.

THE BAXTER MOTOR.

A ¼-horse-power Baxter motor, made by the Baxter Electric Manufacturing and Motor Company, of Baltimore, Md., is shown in Fig. 7. The Baxter motors are made for both constant current (arc light), and constant potential (incandescent) circuits. The very small sizes, $\frac{1}{16}$, $\frac{1}{12}$ and $\frac{1}{10}$ horse-power are made for arc light circuits only, and are specially intended for light-running sewing machines and other similar work. The $\frac{1}{10}$ horse-power motor is in extensive use in driving ventilating fans, pumps, small lathes, scroll saws, etc.

The motors are simple in design and construction, and are claimed to embrace the most careful workmanship. The arc-light circuit motors are supplied each with a switch attached to the base for shutting off the current altogether.

The constant-potential motors are not provided with a switch attached to the base, but in its stead have three binding posts, to which the line wires leading from an independent switch are connected. This independent switch is a combination automatic cut-out resistance-box and hand switch, and is a very valuable adjunct. It enables the operator to perform all the operations necessary in starting a machine of this class by the simple movement of a single lever. When a constant-potential motor is started, the current that passes through the armature is very great, and is only reduced to a safe limit when the machine attains its normal speed. If, on account of overloading or any other cause, the proper speed is not reached very soon, the wire on armature will be burned. If the load is light the start will be very violent, and may do damage either to the motor or machinery it drives. If at any time while the motor is in operation it is loaded down with machinery so as to be compelled to put forth more power than its rated capacity, the current will increase and if it is overloaded enough the increase in current will be sufficient to melt the wire; therefore it is desirable to have some safeguard to protect the machine against such accidents.

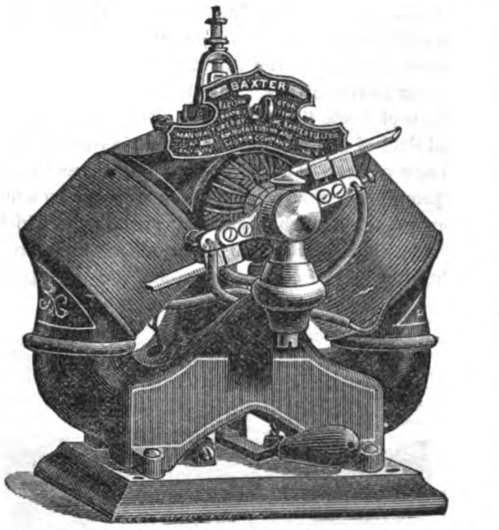

FIG. 7.—MOTOR MADE BY THE BAXTER ELECTRIC MFG. AND MOTOR CO., BALTIMORE, MD.

The Baxter arc light motors range in power from $\frac{1}{16}$ to 10 horse-power, and the incandescent light motors from ½ to 10 horse-power.

(TO BE CONTINUED.)

HOT-WATER HEATING IN AN APARTMENT HOUSE.

FIGURE 1 is a diagram of the heating main, return main and branches, that are supported from the cellar ceiling and connect with the radiators of a five-story house in Brooklyn, N. Y.

H is a No. 131 Gurney hot-water boiler, 40x64 inch, with a 12-inch smoke-pipe and 804 square inches of grate area, catalogued to heat 2,000 square feet of radiator and pipe surface. Owing to a lack of head room the boiler was set in a grouted pit, P, dug for it in the cellar bottom. As the job was needed in a hurry, a boiler was taken from stock which did not have 4-inch couplings to correspond with the direct and return mains R and S, and, to secure full section of connections, each was attached by four 2-inch branches, K K, etc., to the existing couplings. The direct and return branches are of the same sizes at the same places throughout the system, and the lower sections of the risers at A, B, C, D, E and F are of the same size as their connecting branches shown in Fig. 1. N is a 1-inch emptying pipe. The riser A supplies one radiator in the dry room; risers B and D each supply four radiators; risers C and E each supply five radiators; riser F supplies one radiator to warm the halls. The combined net area of radiating surface is nearly 1,400 square feet. All the pipes shown in Fig. 1 are jacketed with asbestos.

The first story of the house is used for a shop, and has only two radiators; the second story is occupied as a residence by the owner, and has four radiators besides that in the hall. Each of the three stories above is occupied by a family, and has four radiators. Figure 2 shows a first floor room arranged as a clothes drying room. It is about 12'x12'x9½' high, and has a set of clothes lines, L L, etc. A simple radiator coil, B, of about 40 square feet surface, is supplied from riser A, Fig. 1, and is designed to heat the room sufficiently to dry the clothes.

Figure 4 shows the connection of the radiators to the risers at E, Fig. 1. Both risers terminate, between the ceiling and floor, in elbows H H, to which the branches F F for radiator A are attached. Below the elbows, and also between the floor and ceiling, are tees to which nipples N N are connected. These have elbows P P, to which the next sections of risers E' E' are screwed. The arrangement is the same at the next floor except that the tees are reversed so as to bring the third set of risers into line with the first, and so on for successive stories, as shown in Fig. 4. These offsets in the risers are made to counteract the tendency that the water would have if the pipe were straight to flow to the top without circulating through the radiator branches.

In Fig 3 the supply to radiator A is through pipe D, which is controlled by valve C; B is an air valve. Figure 5 shows the 25-gallon galvanized iron expansion tank, which is placed in the hall of the upper story. It is connected with one of the fifth story radiators by the 1-inch pipe B, and can be filled from city pressure through the key valve C. D is a 1-inch overflow pipe discharging into an adjacent water-closet cistern.

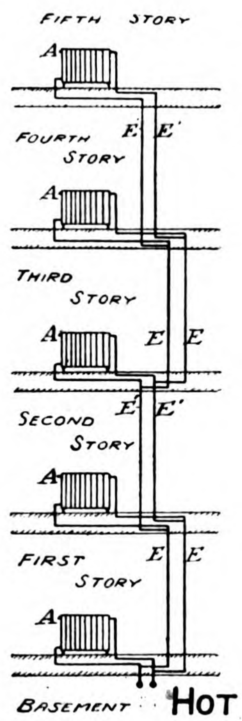
HOT WATER HEATING IN AN APARTMENT HOUSE
"THE ENGINEERING AND BUILDING RECORD"

Fig. 4



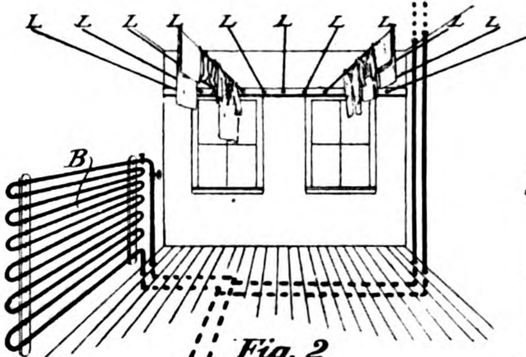


Fig. 2

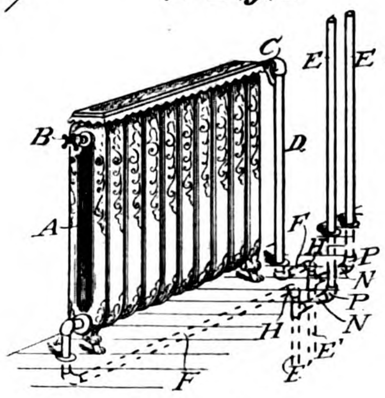

Fig. 3

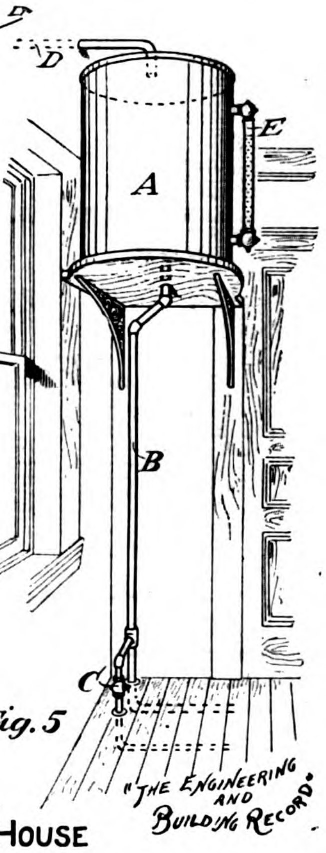

Fig. 5

HOT WATER HEATING IN AN APARTMENT HOUSE

The heating system was designed and put in by Johnson & Co., Catskill, N. Y.

THE interest felt in Europe in the canal system is shown by the international Congress on Inland Navigation, the fourth meeting of which was recently held at Manchester, England, the previous meetings having been at Brussels, Vienna and Frankfort. At this Congress all the leading European nations were represented, and papers were presented bearing on the subject of Inland Navigation in England, France, Belgium, Germany, Austria, Italy, Holland, Russia and America.

PARIS is soon to have its first cable railroad, which will connect the Belleville and Montmartre districts.

THE DANGERS OF ELECTRIC LIGHTING.

IN a paper on the above subject, presented at the recent annual meeting of the National Electric Light Association, Prof. Henry Morton, of Stevens Institute, stated that that part of the electric lighting problem relating to dangers to human life has recently been taken in hand by an organization known as the Employers' Liability Assurance Corporation.

This association, after collecting a mass of material from many sources, has formulated a series of rules for the protection of those employed in erecting and operating electric apparatus involving the use of powerful, and, therefore, dangerous currents. These rules have been generally approved of. From them are quoted the following:

"1st. Do not touch or handle any electric wire or apparatus of any sort while standing on the ground or while in contact with any iron work, gas or water pipe, or stone or brick work, unless your hands are covered with rubber gloves, and you are provided with such properly insulated tools as have been declared to be safe and in good order by the electrician or other competent officer of this company.

"If it is at any time necessary to stand on the ground, or any surface not insulated from the ground, while handling electric wires or apparatus, rubber boots or an insulated stool should be used.

"In moving wires, hanging on or lying over electric light wires, lamps or fixtures, use a dry hand line.

"2d. Never handle any electric wire or apparatus with both hands at once when this can be avoided, and if it is necessary to do so, be sure that no current is present, or that one or both hands are protected by rubber gloves or other efficient insulation.

"3d. When handling line wires, treat each and every wire as if it carried a dangerous current, and under no circumstances allow yourself to make contact between two or more wires at the same time.

"4th. Never open a circuit which has been in use without giving notice to the superintendent, or whoever is in charge, of your intention to do so, and at the same time request that the same line be opened at the main station, and kept open, until you have given notice that your work on that line is complete.

"5th. In the dynamo room never go near the belts or dynamos, nor touch any apparatus unless you are fully informed and instructed how to do so.

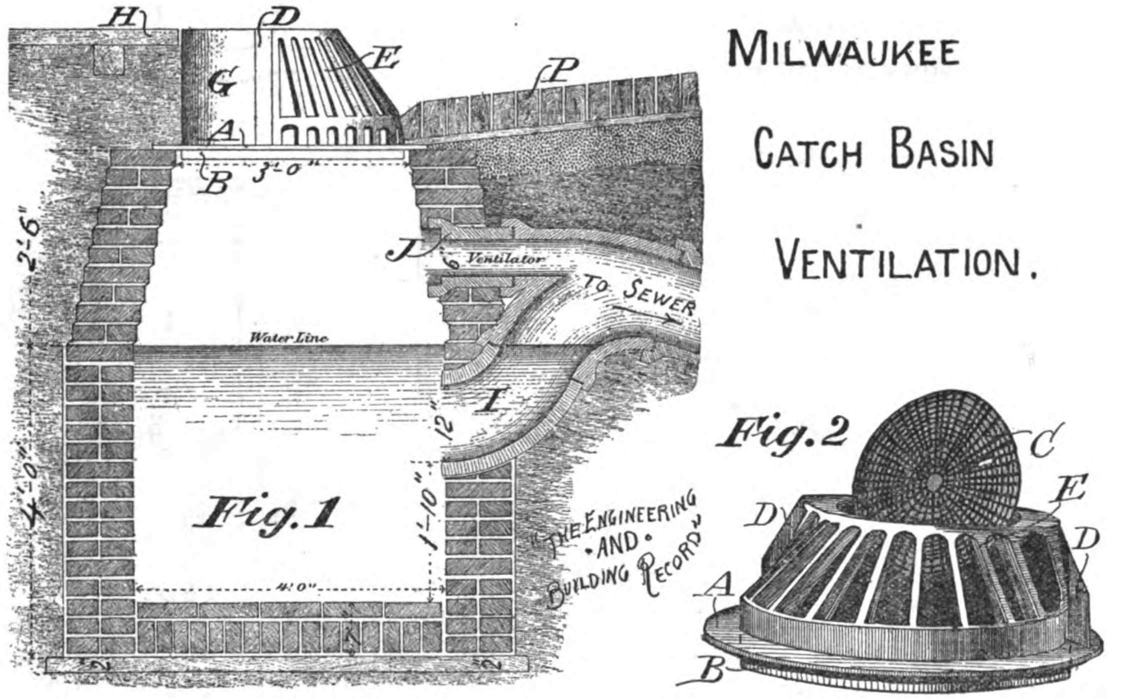
"Tools used by linemen should be provided with insulating handles of hard rubber or other equally good insulator. It is the duty of each lineman to look after his own tools and see that they are in good order, especially as to their insulation.

"6th. Lamp trimmers, and others engaged in the care of lamps, must see that the switch putting the lamp in circuit is turned off before they handle the lamp in any way.

"In construction work a space of at least 20 inches must be left between the holes for pins on the cross arms, so that a lineman may get to the pole and work without danger."

THE UTILIZATION OF FIRE DAMP.

ACCORDING to a report originally appearing in the *Zeitschrift fur das Berg Hutten und Salinenwesen*, and abstracted for the proceedings of the Institution of Civil Engineers, the most elaborate attempt ever made in Europe to obtain from a coal seam a natural combustible gas that should be capable of being used like the natural gas of the American oil region, ended in a conspicuous failure. The mine was situated at Erenenberg, near Aachen, and plenty of gas was apparently forthcoming when it was not wanted. Its systematic removal from the workings, for utilization above ground, was effected by an exhauster connected by a main and branch feeders with every part of the mine. The smallest feeders were 1-inch pipes, which terminated in suction roses perforated on the top side only, which were kept at the top of the levels by means of clamps attached to the timbering. The exhausted gas, which was necessarily a mixture of gases and air, was delivered into a double holder, so arranged that one-half was constantly being filled while the other was emptying. After a time, as this arrangement did not work satisfactorily, the holders were abandoned, and the gas forced by the exhauster directly into the delivery-pipe. The ultimate failure and abandonment of the experiment was due to the irregularity of the gas production in the mine, the air from which sometimes contained as much as 10 per cent. of fire-damp, and sometimes none at all—the variations occurring without any apparent cause, and rendering it impossible to work the exhauster with any reference to the production. The underground collecting arrangements also gave a great deal of trouble, and hindered the work in the headings. The gas, when it could be burnt, was applied to the firing of two boilers; a row of jets being introduced below the firebars from a tube connected with the main, and protected by a water seal. At all the joints of the gas-pipes wire gauze diaphragms, similar to those used in safety lamps, were inserted. The gas did not effect any economy with the boilers. It was also tried as an illuminant with the help of the Fahnejelm magnesia comb; but only the lower third of the rods could be brought to the proper degree of incandescence. The third suggested application of the gas, for driving gas-engines, was not tried.



Novelties.

Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course, be understood that the selection does not imply indorsement.

THE MILWAUKEE CATCH-BASIN VENTILATION.

THE report of the Milwaukee, Wis., Board of Public Works says, in speaking of sewer ventilation:

"The attempt to give an opening for sewer gases by perforating the covers of manholes with two holes of one inch diameter has proved a failure. These openings are too small and too liable to be clogged up by street travel, particularly during the winter months, with snow and ice.

"The simplest and most effective plan appeared to be to ventilate through the catch-basins on the corners of the streets, depending on the multiplicity of the openings and the free diffusion and consequent dissipation of noxious vapor for avoiding any nuisance to street travel.

"The fact that our catch-basins were originally all trapped to prevent floats, such as chips, straw, offal, etc., from finding their way into our sewers without any provision for the free ingress and egress of atmospheric air, made them necessarily a means of concentrating and combining all gases within the sewers.

"It became expedient, therefore, to devise some improvement, if possible, for retaining the usefulness of traps, and at the same time making them a safe and permanent means of ventilation.

"The accompanying drawing (Fig. 1) gives a sectional view of a catch-basin with combined sewer trap, with sewer ventilator attached. The improvement, as shown, consists of a pipe J, constructed in direct combination with the sewer trap I, and molded on to it so as to connect the upper portion of the interior passage of the trap with the interior of the adjacent catch-basin above the water line and with the outer air, thus providing in connection with the trap free ingress of atmospheric air to the connecting sewer and the free egress of noxious air or gas from the sewer, by one integral and economical device. The end of the ventilating pipe extending into the catch-basin is provided with a collar, so that it may be conveniently closed when desired.

"In a total number of 1,818 catch-basins, 199 are thus ventilated, and no complaint having been made against them in all this time, the reasonable conclusion is that they are not offensive to public travel, and that when once generally introduced they must satisfactorily solve the question of sewer ventilation."

The cover shown in the top of Fig. 1 is shown in detail in Figs. 2 and 3.

It has been in use in Milwaukee for several years, and consists of a casting with a round base having a flange A supporting it on the brickwork of the catch-basin. A flange B also extends downward, to prevent the water from washing away the mortar from between the bricks, and holds the cover in place. It is placed at the corner of a street, and forms part of the sidewalk, the back G being closed. The front consists of slanting bars E E, etc., which prevent rubbish from falling direct into the catch-basin. The bars will not hold the rubbish down and clog up like perpendicular bars. The flanges D D are for the pavement or stone to rest against.

When necessary to match the level of the sidewalk H, the height is increased by bolting cylindrical sections to the top, as shown in Fig. 3, the upper one being then fitted with the cover plate C; P, Fig. 1, is the pavement. Slightly modified patterns are employed when the catch-basins are used on the side of the street, not at a corner, or when at a corner not right angled.

The cover is made by G. Campbell & Sons, Centennial Bell and Iron Foundry, Milwaukee, Wis.

TRADE PUBLICATIONS.

THE C. & C. ELECTRIC MOTOR.

The C. & C. Electric Motor Company, 402-404 Greenwich Street, New York, have just completed a new catalogue devoted to the interests of their electric motor and motor combinations. Besides being a very attractive specimen of trade literature, with stiff covers, it contains a good deal of information of the kind in which popular interest now centers. The electric motor business has reached such prominence that particulars of the work to which the motors are adapted, the sizes and capacities in which they are made, their prices, and other allied data, are much sought after by prospective users, and it is to supply such information that the catalogue has been prepared. It is handsomely illustrated, showing different forms of "C. & C." motors and methods of application to various kinds of work, such as hoisting, driving ventilating fans and blowers, working church organ bellows, etc. A number of tables are added, giving capacities, speeds, and dimensions of the motors and special motor outfits. The closing pages contain directions for setting up and operating the motors, and testimonials from a number of users.

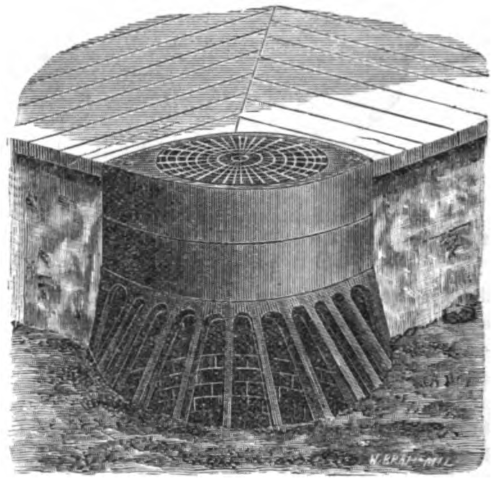


FIG. 3

THE DUNNING STEAM AND HOT-WATER BOILER.

The New York Central Iron Works, of Geneva, N. Y., are sending out a newly prepared circular giving illustrations and particulars of the Dunning boiler made by them. This boiler, as is no doubt well-known to many, is intended for both steam and hot-water heating. Different designs, magazine and surface burning, brick set and portable, are shown, and an extensive table of sizes, capacities, and prices is added. What may be taken as a mark of popularity of the boiler and of a wide circle of its acquaintances is the fact that the maker's name has not been given in the circular. Doubtless, however, this will prove no great obstacle to reaching them.

THE successful completion of the St. Clair Tunnel has stimulated projectors, and a company has been organized to build a similar tunnel under the Detroit River from Detroit to Windsor. This would be about 3,000 feet long under the river, and the approaches would be about 3,000 feet on either side, making a total length of about 9,000 feet. The top of the tunnel would be 48 or 50 feet below the water level, or from 13 to 15 feet below the river bed at the center. The estimated cost is $3,500,000 for a single-track tunnel, and the plan is to have it open to all connecting railroads.

THE pressure of natural gas wells in Indiana and Ohio is steadily diminishing, the diminution having already amounted to between 30 and 40 per cent. Professor Orton urges the imperative necessity of cities and States taking action to restrict wasteful use of gas; but even the strictest regulations, he says, cannot prevent the exhaustion of the supply in a few years.

THE NEW RIVER AND HARBOR BILL

In addition to appropriating money for work, as reported in THE ENGINEERING AND BUILDING RECORD for October 4, the River and Harbor Bill directs the Secretary of War, at his discretion, to cause examinations or surveys, or both, to be made, and the estimated cost of improvement to be estimated, at the following localities:

ARKANSAS.

Clarenden and the lower White River, to determine the effect of back water from the Mississippi River and its cause, and the means and cost of preventing injury therefrom.

ARIZONA.

Colorado River above Yuma to Eldorado Canyon, to determine the advisability and probable cost of improving said river; Sucarnochee River, from its mouth to the Mobile and Ohio Railroad Bridge; Mouth of Gunter's Creek at Guntersville, with the view of ascertaining the practicability and approximate cost of so improving the same as to secure a safe landing above high water mark; Alabama River, to ascertain cost of securing a six foot channel at low water from mouth to Wetumpka.

CALIFORNIA.

Sacramento and Feather Rivers, to be considered by a board of three United States engineers, with a view to project for future improvement; San Rafael River; San Simeon Bay; Alviso Harbor and straightening, deepening, and improving of Alviso Creek; harbor of refuge at Santa Cruz; improving and straightening Redwood Creek; Mokelumne River, for snagging; Redondo Beach Harbor.

CONNECTICUT.

Connecticut River, from Long Island Sound to Hartford, with a view to such improvement as will keep the channel from shifting its course at certain places; Shaw's Cove, New London Harbor; Connecticut River below Hartford; Saugatuck River; Stamford Harbor, Stamford; Cos Cob or Miamus River; Stony Creek River at Stony Creek.

DELAWARE.

Murderkill River; Broad Creek River; Mispillion River, with a view of cutting a canal so as to shorten the distance to the bay, and making an outlet in the bay which would furnish deeper water.

NORTH DAKOTA.

Creel's Bay, Totten Bay, and Minnewauken Shoals, in Devil's Lake, with an estimate of the cost of improving the same by dredging or otherwise, so as to re-establish the navigation of said lake.

NORTH DAKOTA AND MINNESOTA.

Red River of the North, with a view of improving the navigation of the same by the construction of a lock and dam at Goose Rapids in said river.

FLORIDA.

Charlotte Harbor; Peace River; channel lying north and west of the town of Cedar Keys, known as Boat or Number Four Channel; Indian River between Titusville and Jupiter Inlet; St John's River, from Jacksonville to Sanford, to obtain an estimate of the cost of deepening the channel so as to secure navigation for ocean steamers, and to report separately the cost of opening the channel of the river in the vicinity of Orange Mills; the upper part of the St. John's River, from Lake Monroe southward, or in a southerly direction through the river and connecting lakes to the head of steamboat navigation; St. Augustine, for improvement of channel so as to make a deep sea channel over the outer and inner bars.

GEORGIA.

Chattahoochee River, Georgia and Alabama, between West Point and Franklin; the inside route between Savannah, Ga., and Fernandina, Fla., with a view of obtaining a steamboat channel of seven feet depth at mean low water; the inside route between Doboy and Sopelo, with a view of making the same navigable for sea-going vessels; Brunswick Outer Bar, to determine the feasibility and cost of deepening the same to 26 feet at ordinary high water; Yellow River, from the Railroad Bridge near Covington to the Ocmulgee, with a view of obtaining a steamboat channel of five feet deep at mean low water.

ILLINOIS.

Mississippi River at Warsaw, Ill., with a view of removing bar; Slough at Hamilton, with a view to dredging out the same; Illinois River from La Salle to the Mississippi River, as recommended by Capt. W. L. Marshall, corps of engineers, in his report dated March 10, 1890, with a view to ascertaining what lands would be subject to overflow by the construction of a navigable waterway between Lake Michigan and the Mississippi River, but not more than $25,000 of the money appropriated for surveys shall be allotted to this river.

INDIANA.

Wabash River from Terre Haute to La Fayette with a view of removing obstructions of snags and bars and re-establishing the navigation of said rivers between these cities; with a view to improving the Ohio River, between the mouth of Green River, in the State of Kentucky, and the city of Evansville, in the State of Indiana, and confining the waters of the first named river within its present channel, and preventing danger to navigation from any changes therein, the Secretary of War is hereby authorized and directed to make, or cause to be made under his direction, a complete survey of the Ohio River between the points named, together with full estimates of any expenditures that may be necessary to prevent any injuries or threatened injuries to its permanent use and navigation.

IDAHO.

The Upper Snake River, between the Huntington Bridge and Seven Devils Mining District in Idaho, with a view of overcoming obstructions to steamboat navigation.

IOWA.

Mississippi River at and above Clinton, Iowa, with view of removing bars north of Little Rock Island.

KENTUCKY.

Russel's Fork of the Big Sandy River with a view of removing obstructions from the same; harbor of Owensboro, Ky., on the Ohio River; harbor of Smithland, Ky.

KENTUCKY AND TENNESSEE.

Mississippi River from high water mark Lake County, Tenn., to high water mark Fulton County, Ky., north and west of Reef Foot Lake, to ascertain if navigation of the river may not be improved by restraining the flow of water into said lake and adjoining lowlands; Green River, Ky., above the mouth of Big Barren River, completing survey with a view of extending slack-water navigation on Green River; Big Barren River, Ky., above Bowling Green with a view of extending slack-water navigation by additional locks and dams.

LOUISIANA.

Bayou Terre Bonne from Houma to Thibodeaux; Bayou Black to connect with Terre Bonne; Berwick's Bay to the Gulf, with a view of obtaining a deeper channel; Bayou Teche from Saint Martinsville to Port Barre; Bayou Vermillion, bay and passes; Bayou Black for connection between Calcasieu Lake and Sabine Lake; Bayou Des Glaises, with a view of clearing the stream of obstructions from the Atchafalaya River to Cottonport; Mermenton River, including its tributaries and course through Lake Arthur and Grand Lake to the Gulf of Mexico; Bayou Cocodrie, in Saint Landry Parish; Cane River, with a view of improving the same by locks and dams for the purpose of giving permanent navigation the year round; Shoals on Lake Pontchartrain near the Rigolets, known as the "Middle Ground," with a view of dredging a channel ten feet deep and revetting sides of the same; Bayou Castor; Corsica Shoal, situated at the lower end of Lake Huron, near the entrance to the Saint Claire River, with a view to its removal; the American channel of the Detroit River, beginning at the western boundary of the city of Detroit, and from thence continuously in American waters to Lake Erie, with a view to deepening said channel to the same depth as has been attained and is contemplated under present plan in the Canadian channel of said river, the said survey to be made in the channel of said river fronting the towns of Springwells, Ecorse, Monquagon, and Brownstown, and the American shore of said river to such a point in Lake Erie as may be necessary to reach a proper depth of water in said lake to correspond with the increased depth of the river contemplated by this bill; Rouge River, with a view of locating and constructing basin in said river, at a point on the same within four miles of its junction with the Detroit River, convenient for the turning and anchoring of vessels in the same; ship-channel, 20 feet in depth and of a suitable width in the shallows of the connecting waters of the lakes between Chicago, Duluth and Buffalo; Grand River, below Grand Rapids, with a view of determining the existence or non-existence of underlying rock, the hydraulics of the river and the detailed topography of the valley subject to overflow; re-survey and re-location of harbor line in Portage Lake, Houghton County, Michigan, in conformity with the provisions of recent law.

MINNESOTA.

Red River and tributaries above Fergus Falls and Crookston, and of Big Stone Lake, with a view to improving navigation thereon by the erection of suitable dams or by such other means as may be deemed best, together with an estimate of the cost: the Saint Louis River from Grassy Point in Saint Louis Bay to Fond du Lac, or the State line between Minnesota and Wisconsin.

MISSOURI.

Current River, from Van Buren River, Missouri, to its mouth; Missouri River, from the old mouth of the Platte River, Little Point, to a point opposite the city of Leavenworth, also of the river at the city of Western, Missouri, with a view of returning said river to its ancient channel, and the best plan of accomplishing the same.

MONTANA.

Missouri River, between Sioux City and Fort Benton; Missouri River, between Great Falls and canyon next below Stubbs Ferry; Tongue River, with a view of determining the practicability and approximate cost of straightening the channel of said river, immediately west of Miles City and north of the Northern Pacific Railroad track; Nebraska and South Dakota, Missouri River from the mouth of the Big Sioux River to the north line of the State of South Dakota; Yellowstone River, from its mouth to the mouth of Tongue River; Bayou Chevreuil and Bayou Tigre from Lake Des Allemands to points near Vacherie, Chigby and Malagay settlements in Saint James Parish for removal of bars and other obstructions to navigation.

MARYLAND.

La Trappe; Turner's Creek; Rock Hall Harbor; Nanticoke River, the northwest fork of the same; Linchester River; Patapsco River, from the Craighill Channel to the sugar refinery wharves, Curtis Bay; Susquehanna River, above Havre de Grace; Broad Creek; Warwick; Piscataway Creek; Saint Leonard's Creek; Newport Creek, head of Wicomico River, Charles County; Smith's Creek; Eastern Branch of the Potomac River, including that portion in District of Columbia; Saint Jerome Bay.

MASSACHUSETTS.

Canapitsit Channel, between the Island of Cuttyhunk and Neshawana, with a view of deepening the same and clearing the channel from obstructions to navigation; Menemsha Bite, an outlet into Vineyard Sound on the north shore of the island of Martha's Vineyard, with a view of preventing the closing of said inlet; Kingston Harbor, with a view to its improvement; Town River; shoals at the mouth of North River, with a view of removing the same and other obstructions; North River, Solem, from Beverly Bridge to the North Street Bridge; Mystic River, and the Malden River, a tributary of the Mystic, from the bridge of the Boston and Maine Railroad, eastern division, to the head of navigation on said rivers; Weymouth Back River; Essex River.

MAINE.

Kennebec River, from Waterville to steamboat wharf at Augusta, Me.; Sullivan Falls, Hancock County, Me., with a view to its improvement for navigation; Lubec Channel; Harbor of Bluehill, with especial reference to the removal of the ledges known as Middle Ground, eastern and western; Penobscot River; Pepperell Cove, forming the eastern boundary of Portsmouth River Harbor.

MICHIGAN.

Sebewaing River, with a view of deepening the channel from the mouth to the village of Sebewaing to the depth of eight feet.

NEW JERSEY.

Hackensack River, from below the Newark and New York Railroad Bridge, on Newark Bay, to the town of Hackensack; Pensauken Creek; Toms River; Little Egg Harbor Bay and Inlet including Great Bay with reference to establishing a harbor of refuge; Sound between Barnegat Bay and Great Egg Harbor Bay; Shark River; Goshen Creek; Cape May City, for breakwater; thoroughfare from Cape May to the Great Bay north of Atlantic City.

NEW YORK.

Buttermilk Channel and Gowanus Bay channels in New York Harbor, with a view of straightening the same by removing the shoals opposite the southeast side of Governor's Island, protecting the channels by a sea wall on Governor's Island, and to provide for the full width thereof a uniform depth of 26 feet at mean low water throughout these channels along the wharves of Brooklyn from a point opposite Wall Street Ferry to the foot of Bryant Street, Brooklyn; Bay Ridge Channel, with a view of removing the shoal and providing a uniform depth of 23 feet at mean low water opposite the Bay Ridge shore to the 23-foot curve in the New York Harbor; Hudson River at Cornwall from the Moodna River, otherwise known as Murderer's Creek, to the channel or deep water of the Hudson River; Inner Bay near mouth of Saranac River at Plattsburg, for harbor of refuge; Sag Harbor, Suffolk County, for breakwater; Princess Bay, Staten Island, for breakwater; Peconic River, Suffolk County, and Mattituck Bay, Suffolk County, for breakwater; from main channel from Jamaica Bay easterly to Long Beach Inlet, for canal; Champlin's Creek, in town of Islip. That the Secretary of War is authorized and directed to appoint a board of three officers of the Corps of Engineers, United States Army, whose duty it will be to thoroughly examine the obstructions to navigation in the Hudson River, between New York City and the State dam at Troy, New York, and report a project and estimate of the cost of widening and deepening said river between New York City and the city of Albany, and also between New York City and the State dam at the city of Troy for the navigation of sea-going vessels drawing 20 feet of water, and also a separate estimate of the expense of improving the river between Coxsackie and the State dam at Troy, to such an extent as to secure a navigable channel 12 feet deep at mean low water. Said board shall accompany their report with a statement as to the usefulness of such improvements and of their relations and value to commerce, and of the advisability of entering upon the same at this time; and the Secretary of War shall transmit said reports to Congress with his own views and those of the Chief of Engineers, United States Army thereon, and the expenses of said board shall be paid out of the appropriation made in this act for the improvement of the Hudson River, not to exceed $10,000; Boquet River, from mouth on Lake Champlain to Willsborough, New York; Bronx River; Port Day, above Niagara Falls; Westchester Creek, Westchester and New York Counties.

NORTH CAROLINA.

Waterway from Pungo River to the town of Sladesville: Northwest River up to Moyock; Drum Inlet; Waterway between Pamlico River and Bay River; White Oak River from Roberts' Landing to Collins Crossing; harbor of Washington, Pamlico River.

OHIO.

Conneaut Harbor; Grand River between Richmond and the mouth.

OREGON.

Tillamook Bay and Bar; Alsea Bay and River; Coos Bay, for improving upper harbor by removal of shoals and in dredging; the Lower Willamette and Columbia Rivers, with a view of securing 25 feet at low water from Portland to the mouth of the Columbia; the Yamhill River from its mouth to McMinnville, with a view of improving the same by removing snags and other obstructions; Willamette River, deepening channel on west side of Swan Island, improvement of navigation at Clackamas Rapids and Ross Island and near city of Corvallis; Lower Columbia River, on south side, between Astoria and Wood's Landing, for snagging; Young's Bay channel from the ship channel of the Columbia River to the head of Young's Bay, a distance of 1½ miles, with a view to improving the same by dredging, so as to secure a depth of 18 feet at low tide; Lewis and Clarke's River, for snagging; Coquille River, for deepening channel from Coquille City to Myrtle Point to four feet at mean low depth.

PENNSYLVANIA.

Delaware Bay, with a view of determining the best site near the mouth of the same for a National harbor of refuge suitable for deep draught vessels. The examination to be made by a commission of three engineer officers, who will make the examination and submit to the Secretary of War a report thereon with a project and estimate of cost of construction of such a harbor of refuge; the west branch of the Susquehanna River in the State of Pennsylvania, in order to ascertain if the navigation of said river can be materially and permanently improved by the construction of embankments or otherwise; such survey also to be made with a view of ascertaining the best practicable method of confining the waters of said river in times of great flood, to the general course of its channel; Tionesta, from the town of Tionesta, to the village of Balltown, with a view to the improvement and the removal of obstructions.

RHODE ISLAND.

Watch Hill Cove, in Little Narragansett Bay; Narragansett Bay Channel, between Starve Goat Island and the main land, with a view of deepening the same; Newport Harbor, south of Goat Island, with a view to the removal of the Spit at the south end of the Island.

SOUTH CAROLINA.

Wateree River, from Camden to the falls of the Catawba, also of the bend or curve in said river about four miles below Camden, between the plantations of Witte and Williams, to determine if it is advisable in the interest of navigation to make a cut-off across the neck of said bend; Black River, from Kingstree to its mouth.

TENNESSEE.

Obion River, from its mouth to the crossing of the Louisville and Memphis Railroad in Obion County; Little Pigeon River, from mouth to Sevierville; Memphis Harbor, especially for the removal of the bar forming opposite the upper part of the city or the prevention of the river bank taking the form that the natural forces are now giving it.

TEXAS.

Brazos River, from its mouth to Waco; Sabine River, from where said river empties in Sabine Lake to Sudduth's Bluff, on said Sabine River; survey to remove obstructions at mouth of Double Bayou in Chambers County, to remove obstructions; Colorado River, with a view of removing raft at mouth of same; St. Charles Bay, with a view of removing obstructions at mouth of same; Aransas Bay, to remove Half-Moon reef; West Galveston Bay, from Christian's Point, with a view of reopening the channel through West Bay; Trinity River, from its mouth to Dallas.

VIRGINIA.

Waterway to connect Lynn Haven Bay with eastern branch of Elizabeth River; Potomac Creek; Chickahominy River, from Holly Landing to Long Bridge; Tangier Harbor; Wicomico River; Nottoway River, from mouth of river to Courtland; West Neck River, to and beyond Dozier's Bridge; western branch of Elizabeth River; Upper Machodoc Creek; Crane's Creek; Nandua Creek; Piscataway Creek.

WEST VIRGINIA.

Elk River, with a view of improving the same by locks and dams.

WASHINGTON.

Nooksack River, Skagit, Snohomish, D'Wamish, Black, Puyallup, Nasal, North, Gray's Deep, Skamakawa, and Crooked Rivers; Gray's Harbor and Bar, and extending up Chehalis River to Montesano; Gray's River, for snagging; Swinomish Slough, with the view of constructing a ship channel through the same, connecting Saratoga Passage Skagit Bay with Padilla Bay, and to report the most suitable and feasible plan for making such improvement, with the cost of the same; Shoalwater Bay, from and including its entrance to South Bend, about two miles up the Willapah River, and from said South Bend, about ten miles up said river, to Woodward's Landing, with a view to improving the same for navigation; Olympia Harbor, from deep water in Budd's Inlet to Fourth Street Bridge in the city of Olympia, and separately from said bridge to the mouth of the Des Chutes River at Tumwater, and to report as to the most practical and convenient channel and the most feasible, economical, and suitable plan for improving the same for navigation by the class of vessels employed on Puget Sound, and also to cause to be made an estimate of the cost of each of such improvements; Columbia River, from the mouth of Willamette River to the upper limits of the city of Vancouver, with a view of establishing a ship channel; for a ship channel between Port Townsend Bay, Puget Sound and Oak Bay.

WISCONSIN.

Allonez Bay at the west end of Lake Superior, also the Nemadji River for a distance of four miles above its mouth, with a view of determining the best method of improving and making them available as a portion of the harbor system of the city of Superior; Harbor at Hudson, with a view to prevent the city being cut off from the navigable channel of the Saint Croix Lake, as a result of the Government dike now constructed at that point, and with a view to the feasibility of conducting the waters of Willow River past the city of Hudson into the navigable channel of the lake.

VIRGINIA AND MARYLAND.

Potomac River, up to the City of Washington, with the view of removing obstructions and deepening the channel.

SECTION 18. That for examinations, surveys and contingencies, and for incidental repairs, for which there is no special appropriation, for rivers and harbors $225,000; Provided, That no survey shall be made of any harbors or rivers until the Chief of Engineers shall have directed a preliminary examination of the same by the local engineer in charge of the district, or an engineer detailed for the purpose, and such local or detailed engineer and the division engineer of the locality shall report to said Chief of Engineers whether, in their opinion, said harbor or river is worthy of improvement, and shall state in such report fully and particularly the facts and reasons on which they base such opinions, including the present and prospective demands of commerce; and it shall be the duty of the Chief of Engineers to direct the making of such survey, if, in his opinion, the harbor or river proposed to be surveyed be worthy of improvement by the general Government; and he shall report to the Secretary of War the facts, and what public necessity or convenience may be subserved thereby, together with the full reports of the local engineer; and provided further, that no survey for new works other than those designated by law shall be made, and the Government shall not be deemed to have entered upon any project for the construction or improvement of any waterway, harbor or canal mentioned in this act unless or until the work of construction shall have been actually appropriated for. Said reports of preliminary examinations and surveys shall be made to the House of Representatives, and are hereby ordered to be printed when so made.

GAS AND ELECTRIC LIGHTING.

LUDLOW, KY.—The subject of public lighting is being discussed at this place.

GRENADA, MISS.—Electric lights are proposed for this place.

HASTINGS, MICH.—An electric light plant is to be established at this place.

VENICE, ILL.—The Village Board has granted a franchise to Gustavus Niemann and others for the establishment of an electric light and power plant. The ordinance conveys a monopoly of 20 years, with a limit of one year in which to complete the work. The village is given the privilege of having as many lights as required at 10 per cent. below current rates.

DARIEN, GA.—It is probable that operations will soon be commenced on the electric light plant proposed for this place.

YORK, PA.—Important improvements are soon to be made to the local gas works.

SHIPPENSBURG, PA.—A company has been organized, the object of which is to establish an electric light plant here. Estimated expenditure, $10,000.

MANCHESTER, VA.—The citizens of this place will decide the electric light question at a public election to be held soon.

MARION, PA.—New gas works will be established at this place by M. C. Watson and others, who will expend $250,000 on the project.

KINGWOOD, W. VA.—This place is to have electric lights at an early day.

RIVER FOREST, ILL.—The people of this place have voted in favor of electric lights.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE.

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-306.

LACK of space compels us to omit a list of projected buildings in New York, Brooklyn and Philadelphia.

WATER.

For Additional Water Items see Proposal Columns.

LANCASTER, PA.—The experts who have been investigating the water-works matter at this place, have submitted a report recommending the construction of a new reservoir of about 40,000,000 gallons capacity; also the addition of a new pumping engine with a capacity of about 12,000,000 gallons.

ALEXANDRIA, LA.—The City Council is considering the water-works matter, and is called upon to decide whether a water-works or electric light plant should be established, as the taxpayers do not favor having both at once.

MADISON, N. J.—Water-works are being constructed here by Moffett, Hodgkins & Clarke, under the superintendency of Edward O. Geran.

GREELEY CENTER, NEB.—City Clerk J. B. Gaffrey writes: "We are not ready at present to do anything in regard to water-works; not before spring. When we are I shall inform you."

HARDWICK, VT.—Postmaster Ira A. Shattuck writes: "Messrs. Aiken & Bridgman are to put in a system of village water-works sufficient for fire and domestic purposes—large enough for a village of 3,000 to 5,000 inhabitants."

WESTFIELD, PA.—The sum of $25,000 is to be expended on a water-works plant to be established at this place by a company of which J. H. Miller is president.

MADISON, ILL.—The Madison Water-Works Company will soon erect a plant at this place, at an estimated outlay of $20,000. Charles D. McLene can furnish particulars.

DOVER, N. J.—Important improvements and extensions are soon to be made to the local system of water-works.

CHAMBERSBURG, PA.—The water-works project at this place has progressed so far that proposals for doing the work will soon be wanted.

KALKASKA, MICH.—The work on a system of water-works here is to be commenced immediately by the Michigan Pipe Company, of Bay City, Mich. About 3½ miles of Wyckoff pipe, 30 hydrants and valves, special castings, etc., will be used.

BELVIDERE, ILL.—A complete system of water-works is to be established at this place.

LA GRANGE, GA.—The establishment of a system of water-works is now being agitated in La Grange, and a vote by the citizens, for or against the issuance of bonds for that purpose, will be held some time soon.

CHICAGO, ILL.—The Finance Committee of the City Council has decided to recommend the construction of a new water supply system for Lake, a suburb of this city, at a cost of $1,000,000.

LINCOLN, ILL.—Regarding the report that this place was to have water-works, John H. Starkey, City Clerk, writes: "We have a good system of water-works, that was put in in 1886 by New York parties."

ATLANTA, GA.—The Hall Bros., civil and mining engineers, have completed a report of their survey of a waterway to North Peachtree, estimating the cost at $223,000.

BUTTE, MONT.—The surveyors for the Silver Bow Water Company's new pipe line from the head of German gulch have reported the additional water supply to the city from that gulch is just what is wanted, and that operations can proceed at once.

SAVANNAH, GA.—The Savannah Water Company will extend its mains to Petersburg, a suburb of this city.

COLDWATER, MICH.—The following proposals for certain furnishings for the water-works system at this place, have been opened.

BIDDER.	VALVES.						HYDRANTS.

*Awarded contract. Boxes only—Brigham and Fay Company, $361.75. Boxes each—Holyoke Hydrant and Iron Works, $425.

PUMPING STATION.—George Camike, Coldwater, deductions made, $8,208; Campbell & Baer, Hillsdale, Mich., complete, $8,333; Brown & Sherman, amended bid, Coldwater, Mich., $7,566; Moffett, Hodgkins & Clarke, complete, $7,800.

PUMP WELL.—Brown & Sherman, Coldwater, 20 feet deep, $725; 25 feet deep, $1,014; 30 feet deep, $1,582; 40 feet deep, $2,720; Moffett, Hodgkins & Clarke, Syracuse, N. Y., 20 feet deep, $2,500; 25 feet deep, $3,500; 30 feet deep, $5,000; 40 feet deep, $7,000; Dowagiac Construction Co., Dowagiac, Mich., 30 feet deep, $3,700; T. C. Brooks, Jackson, Mich., 30 feet deep, $6,000.

ARTESIAN WELL.—Dowagiac Construction Co., Dowagiac, Mich., for 8 6-inch wells, 50 feet deep, $2,161.14; 65 feet deep, $2,464.17; 70 feet deep, $3,562.34; 75 feet deep, $2,663.50; 80 feet deep, $2,760; strainers for all, $280 extra; Island City Well Co., Eaton Rapids, Mich., all $250 per foot for 6-inch wells; National Water Supply Co., 6 wells, $2,385; 10 wells, $4,305; Cook Well Co., St. Louis, Mo., 6-inch well, 55 feet deep, $240, each well; 8-inch well, 55 feet deep, $294; 6-inch well, 95 feet deep, $335; 8-inch well, 95 feet deep, $415.

PUMPING MACHINERY AND BOILERS.—Hughes Steam Pump Co., 12-horse power, four bids, as follows: $4,000, $3,460, $3,510, $2,890; Lansing Iron and Engine Works, boilers only, $1,794; Erie City Iron Works, boilers only, $1,485; Jackson Foundry and Machine Co., boilers only, $1,600; Holly Manufacturing Co., engine, four bids, as follows: $2,500, $3,500, $2,800, $3,900. Price of two pumps twice that of one, less 10 per cent of the total amount. Deane Steam Pump Co., engine, $5,630; E. Mansell, complete, $2,603.

MASON CITY, ILL.—Considerable pipe will soon be wanted at this place for the water-works plant, which is at present under way.

TARBORO, N. C.—The water-works question is still the all-absorbing topic at this place.

BUENA VISTA, GA.—According to reports the water-works system projected for this place will soon take shape.

SUTTON, NEB.—The following bids for constructing a water-works system were received by A. A. Richardson, Lincoln, Neb., Oct. 1, Contracts awarded as follows: Porter Boiler Manufacturing Co., Chicago, stand pipe, $2,500; boiler $500; John McCarthy, Wymore, Neb., base of stand-pipe, $900; Tamaqua Mfg.Co., hydrants, $783; Bourbon Copper and Brass Works, Cincinnati, valves, $193; E. C. McCushland, Grand Island, Neb., pipe laying, 8, 6 and 4-inch, 19 cents per foot; Fredericks & Wentz, Sutton, Neb., house, $700; South St. Louis Foundry and Pipe Co., St. Louis, pipe, $33; special, $56. All bids on wells and machinery rejected.

WESTCHESTER, PA.—The Water Committee of the Borough Council has for several days been prospecting in the eastern part of West Goshen township for a more adequate supply of water for the town, the recently established industries in the place having made such a step necessary.

ATLANTA, GA.—The *Atlanta Constitution* publishes the following proposals for the construction of a new water supply, on the two lift scheme at this place, which were opened October 1, by the General Committee on new Water-Works:

Filters.—National Water Purifying Co., New York, $24,900, bid including buildings, etc; Hyatt Pure Water Co., New York, $26,704.

Pumping Engines.—Holly Manufacturing Co., Lockport, N. Y., 6,000,000-gallon engine, $28,120 and $41,600; 10,000,000-gallon engine, $49,900 and $72,800. Henry R. Worthington, 6,000,000-gallon engine, $37,000; 10,000,000-gallon engine, $40,000.

Boilers.—Atlanta Machine Works, $14,700; Holly Manufacturing Co., $21,240.

Pipe.—Anniston Pipe Works, W. F. Plane, agent, cast-iron pipe and specials as per printed advertisements, 20, 30 and 36-inch cast-iron pipe, $22.95 per ton; specials at $2.35. W. H. Merigold, Anniston, Ala., 36-inch pipe, $5 per lineal foot; 30-inch pipe, $1.25 per lineal foot; 20-inch pipe, 85 cents per lineal foot. For solid rock excavation add $1.25 per cubic feet. R. D. Wood & Co., Philadelphia, 33, 30, 20-inch pipe, $25 per ton; specials, 2½ cents per pound; Y's and breeches, 3 9/10 cents per pound. The McNeal Pipe and Foundry Co., Burlington, N. J., 36, 30, 20-inch pipe at $29.71 per ton; specials, 2¾ cents per pound. The Addyston Pipe and Steel Co., Cincinnati, O., pipe, $28 per ton; specials, $60 and $80. Dennis, Long & Co., Louisville, Ky., pipe at $25.80 per ton; specials, 3 cents per pound. Howard-Harrison Iron Co., Bessemer, Ala., pipe, $22.24 per ton; specials, 2½ cents per pound. E. Sutphin, St. Louis, Mo., 20-inch pipe, $3.25 per lineal foot; 30-inch pipe, class B, $5.76 per lineal foot; 30-inch pipe, Class C, $6.24 per lineal foot; 36-inch pipe, $9.25 per lineal foot; valves, 20-inch, $145; valves, 30-inch, $420; valves, 36-inch, $570. This bid includes the laying of pipe. 20-inch pipe, 80 cents per lineal foot; 30-inch pipe, $1.48 per lineal foot; 36-inch pipe, $4.67 per lineal foot. Gloucester Iron Works, Philadelphia, 36-inch pipe, $28.91 per ton; 30-inch pipe, $28.91 per ton; 20-inch pipe, $28.91 per ton; special castings, above sizes, $55 per ton. Dunn Bros., Birmingham, Ala., or Rome, Ga., 36-inch pipe, 75 cents per lineal foot; 30-inch pipe, 52 cents per lineal foot; 20-inch pipe, 36 cents per lineal foot.

Valves.—Bids to furnish valves for the works were received from the Eddy Valve Co., Waterford, N. Y., and the Ludlow Valve Manufacturing Co., Troy, N. Y.

The following are the bids on a scheme contemplating only one lift. These bids were presented by request of the Water-works Committee, at a subsequent session. The H. R. Worthington Co., of New York, put in a bid reading: For two 7,000,000-gallon engines, $85,000; a 10,000,000-gallon engine, $17,250, and nine boilers, $16,047. The Holly Co.'s bid was: For two 7,000,000-gallon engines, $99,000; a 10,000,000-gallon engine, $22,500, and eight boilers, $1,600. The one-lift scheme suggest two 7,000,000-gallon engines at the river, with 10,000,000-gallon engine to raise the water from the river to the reservoir. The bids were referred to a special committee. The contract for furnishing the pipe was awarded to the Howard Harrison Iron Company, of Bessemer, Ala.

GALVESTON, TEX.—Some time ago the City Council advertiseed for bids to sink an experimental well, to demonstrate if pure, wholesome water could be obtained by that process. Only one bid was received, and that not being satisfactory, at a meeting of the Council held recently, the Water Committee was authorized to contract with any reliable well boring company which would agree to sink a deep well. The Council has already set aside $24,000 for this purpose, and has authorized the committee having the matter in charge to expend any reasonable amount above that sum for the purpose of securing such a well.

WASHINGTON, D. C.—An exchange publishes the following item: "The acting Vice-Commercial Agent of the United States at Noumea, New Caledonia, informs the Department of State in a dispatch under date of August 14, that the municipal authorities of that city have invited bids for the construction of a projected water supply between the Dumbea River and the city of Noumea. For the information of any American firms who may desire to bid on the work, the acting Vice-Commercial Agent, in his dispatch, informs the department that similar works have been constructed for the city of San Diego, Cal., which presents a remarkable analogy with the situation of Noumea. The Dumbea River is about 30 kilometers from the city. The estimated cost of the work is about 2,500,000 francs ($500,000), the Government will furnish labor at 50 centimes (10 cents) per day. The department will be pleased to aid American firms all they can in obtaining the necessary information to enable them to bid on the work."

MERIDEN, CONN.—The Water Committee has submitted its report to the Common Council on the question of an additional water supply. The report recommends the North Side site as the most available, and places the cost at $200,240. No action has as yet been taken on the report.

RICHLANDS, VA.—It is stated that the contract for constructing a system of water-works at this place has been awarded to Howard Murphy, of Philadelphia, Pa.

EATONTON, GA.—Regarding the report that this place was to have a system of water-works, Town Clerk D. B. Nesbet writes: "There are no prospects for water-works in our town at present."

ROCHESTER, N. Y.—Contracts will soon be let for numerous water-works extensions.

GRENADA, MISS.—At a public meeting held September 24 it was decided to settle the question of water-works and electric light by a special election. The proposition is for the city to father the enterprise by the issuance of $20,000 of bonds, to run 20 years.

EAU CLAIRE, WIS.—Reports say that negotiations are pending for the purchase of the Dells Water Power Company, the Eau Claire Gas Company and the Brush Electric Light Company, by a syndicate of Maine capitalists.

GOSHEN, IND.—There is now a scheme on foot at this place to make an expenditure of $20,000 on a system of water-works.

MISHAWAKA, IND.—A water works company has been incorporated for the purpose of introducing water in this place; capital stock, $20,000. For particulars address Wallace H. Dodge, as above.

RIVER FOREST, ILL.—A water works system is one of the improvements proposed for this place.

MILFORD, MASS.—A new pump, with a daily capacity of 1,500,000 gallons, is to be added to the plant of the local water company.

OCONTO, WIS.—A water-works system, with 11 miles of pipe and 80 hydrants, is to be established at this place.

LEXINGTON, NEB.—A. A. Richardson, engineer, Lincoln, Neb., is drawing plans for $20,000 water-works for this place.

WATER VALLEY, MISS.—The people of this place have voted the sum of $10,000 for water-works, and if the Board of Aldermen indorse their action, operations will soon commence.

San Angelo, Tex.—The President of the San Angelo Water-Works Company, writes: "The City Council is soon to act on our proposition to enlarge, remodel and extend our works. New source of supply, new pumping machinery, additional tower, and 6 miles of cast-iron mains extensions."

Hingham, Mass.—Several thousand feet of water mains are to be laid in this place.

Hebron, Neb.—Plans and specifications are now being prepared for a $25,000 waterworks for this place by A. A. Richardson, engineer of Lincoln, Neb. For further information apply to A. A. Richardson, engineer, Lincoln, Neb.

Jersey City, N. J.—A contract for 200 lengths of 8-inch cast-iron pipe, and 600 lengths of 6-inch, has been awarded to R. D. Wood & Co., of Philadelphia, for $26.95 per gross ton.

Toronto, Ont.—Among the improvements proposed for the water-works system at this place is the addition of two 10,000,000 gallon pumping engines.

Fargo, Dak.—At the meeting of the Council next week steps will be taken to immediately commence to lay mains, as far as the finances permit, in those portions of the city which have hitherto been without a water supply. For particulars address Mayor Ball, as above.

Parkersburg, Pa.—The citizens of this place are taking steps towards organizing a company for the purpose of supplying the town with water.

McKeesport, Pa.—The Superintendent of the water-works at this place has recommended the addition of two compound condensing engines, an additional rising main and a new power house, the entire cost being estimated at $40,000.

Benton Harbor, Mich.—The Board of Trustees of this place has granted a franchise to the Benton Harbor Water Supply Company to establish and maintain a system of waterworks here. Several miles of mains will be laid and 75 hydrants will be used. For particulars address George B. Thayer, City Clerk, as above.

Wilton, Iowa.—The projected waterworks system for this place will cost $14,000.

Waterbury, Conn.—The question of improving the water supply at this place is receiving the attention of the local authorities.

Blaine, Wash.—J. W. Tanner, City Clerk, writes: We have a water-works under construction, which will be completed by the 1st of January, 1891. Franchise granted to the Northwest Water Company, and operated by the same.

Water-Works.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Keithsburg, Ill.; Philadelphia, Pa.; Austin, Tex.; Ashland, Ky.; Berryville, Va.; Toronto, Canada; Rushville, Ind.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

Des Moines, Iowa.—Civil Engineer B. Schreiner writes: "The improvement of the sewerage system of this city consists, besides some laterals of smaller extent, of a 66-inch intercepting sewer, which will be completed before the fall season ends. This sewer will be at present one mile long, with future extension of perhaps another mile. This sewer is calculated to drain about three square miles, and was mainly constructed to facilitate the drainage of cellars and basements, as the underground water in these localities rises to within two to three feet to the surface. The price for this sewer is $5.65 per lineal foot, including manholes and catch-basins."

Joliet, Ill.—A general sewerage system, to cost about $140,000, will likely be projected here next season. Plans were made some time since by Charles H. Ledlie, C. E., of 417 Olive Street, St. Louis, Mo.

Knoxville, Tenn.—It is expected that Colonel Hartford will render his report regarding his survey looking to the construction of a sewerage here very soon, after which the final steps will be taken in the matter by the Board of Public Works.

Sacramento Cal.—The question of a system of drainage for this city is at present being discussed by the local officials. County Surveyor Boyd has just completed a survey of the place, and it is expected that important steps will soon be taken.

Albany, N. Y.—The following proposals were received by the Board of Contract and Apportionment, October 6, for the placing of certain drains: John Doyle offered to lay 2,180 lineal feet of 18-inch pipe for $3 per foot; 916 feet of 15-inch pipe for $2.75 per foot; 3,248 feet of 12-inch pipe for $2.50 per foot; 170 feet of 6-inch pipe for 60 cents per foot; 60 Y branches for the 18-inch, $6.50 each; 33 15-inch Y's, $5.80 each; 94 12-inch Y's, $5.50 each; 15 manholes, $70 each; 4 lampholes, $20 each; 14 receiving basins, $95 each; 60 feet of 3-foot culvert, $4.50 per foot; 200 feet of 2-foot square box drain, $1.50 per foot. William S. Dyer, for the first item, $1.53; second, 95 cents; third, 69 cents; fourth, 25 cents; fifth, $3.25; sixth. $2.25; seventh, $1.95; eighth, 47½ cents; ninth, $10; tenth, $80; eleventh, $1.63; twelfth, $1. John J. Holler, first, $2.18; second, $1.85; third, $1.60; fourth, 25 cents; fifth, $3.85; sixth, $3.05; seventh, $2.60; eighth, $55; ninth, $14; tenth, $95; eleventh, $4; twelfth, 50 cents. William E. Murphy, first, $3; second, $3; third, $285; fourth, 50 cents. fifth, $9; sixth, $8.50; seventh, $8; eighth; $50; ninth, $16; tenth, $90; eleventh, $3.50, twelfth, 60 cents. Thomas Reilly, first, $4.90; second, $4.75; third, $4.60; fourth, $2.30; fifth, $860; sixth, $790; seventh, $740; eighth, $99; ninth, $75; tenth, $190; eleventh, $6; twelfth, $3.

Orange, N. J.—The Citizens' Committee, appointed to confer with the Common Council Committee on the plans for the proposed sewerage system, has submitted its report to the people. The report recommends the house sewerage system, as designated by C. Ph. Bassett, C. E., to which the consulting engineers have given their approval, "provided the ground water drainage is excluded from the house sewers, is complete and sufficient, both for the present and for the forty years next to come." It is also provided that "the ground water piping be connected with the storm water system and not with the house system." The Committee also recommends that the proposed system be adopted by the city, as soon as the power to act is given. Henry Graves is chairman of the Committee.

Far Rockaway, N. Y.—Civil Engineer Thomas D. Smith has been requested by the Board of Sewer Commissioners of this place to prepare two maps, one showing the outlines of a gravity system having one outlet, and then a similar system having two outlets, either to be made available with or without a system of deodorization, as might subsequently be determined upon. These maps are to show the locations of all main and lateral sewer pipes, the necessary depth of cuttings, etc. It is expected that Mr. Smith will make a report at a meeting of the Board to be held in a few days.

Quincy, Mass.—The Committee on Sewerage has submitted its report to the City Council. It recommends the adoption of an act to authorize the city to adopt a system of sewerage or sewage disposal for a part or the whole of its territory, in accordance with any general plans which have been or may be approved by the State Board of Health, the authority to construct, lay, maintain, repair, alter and operate to vest in a Board of Commissioners, to be appointed by the Mayor as soon as practicable after the passage of the act. The matter was laid on the table.

Woonsocket, Mass.—At a meeting of the Business Men's Association of this place, held October 7, the sewerage question was discussed. James Murray is president of the Association.

Scranton, Pa.—It is proposed to establish a system of sewers at South Scranton.

Mt. Vernon, O.—Plans and specifications for the main sewer in Eastern District No. 2 are on file in the office of the City Civil Engineer, who can furnish particulars regarding further operations.

Newport, R. I.—Numerous sewer extensions are to be made at this place.

Iron Mountain, Mich.—John J. Saving, City Clerk, writes: "The sewerage system contemplated by this city has fallen through for the present."

Macon, Ga.—It is stated that John T. Boifeuillet will introduce a bill in the Legislature to sewer this city. After this action is taken the people will be called upon to vote on the question.

Sewers.—See our Proposal Columns fo information regarding sewer construction a the following places: Jersey City, N. J. Dayton, O.; New York City; Denver, Col. Albuquerque, N. M.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

Philadelphia, Pa.—The specifications for the approaches to the proposed bridge over the Schuylkill River at Walnut Street, this city, are now ready and are in the hands of Louis Wagner, Director of Public Works.

Boston, Mass.—The following bids were received October 4 for widening the drew of the North Harvard Street bridge: George H. Cavanaugh, $9,500; Alexander McInnis, $10,153; W. A. Kenrick & Son, $10,169.92; John Cavanaugh, $7,900; May & Ellis, $8,750.

Sioux City, Iowa.—An ordinance requiring the building of a viaduct over the railroad tracks on lower Fourth Street has been passed by the City Council, and the City Engineer has been instructed to make the necessary plans and specifications. The proposition of the Chicago, Milwaukee and St. Paul Co. to build a viaduct over its track on Fairmount Avenue has also been accepted by the Council.

Scranton, Pa.—It is more than probable that this city will pass the ordinance authorizing the erection of several bridges.

Baltimore, Md.—According to reports the Baltimore and Potomac Railroad Co. will soon bridge its tracks in this city.

Charlotte, N. C.—Reports say that the Charlotte, Columbia and Augusta Railroad Co. may erect an iron bridge over its tracks, in this city. Address the Chief Engineer, this city.

McKeesport, Pa.—The proposed bridge, to be known as the Port Vue structure, to span the Youghiogheny River, at Thirteenth Street, is to be erected.

Biddeford, Me.—A new bridge is to be erected at this place. Address the County Commissioners, as above.

Augusta, Ga.—The bridge projected to span the Savannah River, to be built by the North Augusta Company, is soon to be commenced. General Manager James V. Jackson expects to receive the plans and specifications from Grant Wilkins, the contracting engineer of the bridge, and then proposals will be advertised for. It is proposed to open the bids October 20.

Zanesville, Ala.—A new bridge is to be erected over Village Creek, at this place. Address Clerk Miller, of the City Court, for details.

Knoxville, Tenn.—The following bids for the erection of an iron bridge on Fifth Avenue, this city, were received by the City Engineer, October 4: King Iron Bridge Co., Cleveland, O., with Dalton rail, $14,500; with Cincinnati rail, $14,835; Wrought Iron Bridge Co., Canton, O., $15,200; Youngstown Bridge Co., Youngstown, O., $15,450; Smith Bridge Co., Toledo, O., $15,549; Massillon Bridge Co., Massillon, O., $15,600 through truss; $15,700 low truss; Chicago Bridge and Iron Co., Chicago, Ill., $15,789; Edge Moor Bridge Works, Edge Moor, Del., $16,349.

Knoxville, Tenn.—This city is considering plans for replacing the Gay Street bridge with a plate girder one; length, about 600 feet; roadway, 22 feet; two 8-foot sidewalks; capacity 100 pounds over all.

Knoxville, Tenn.—The Cherokee Land Company of this city will build, at an early date, a highway bridge across the Tennessee River here. The bridge will be about 1,200 feet long, including approaches. J. C. J. Williams, President.

Pittsburg, Pa.—The project to construct a bridge from Ella Street, Sixteenth Ward, to Ridge Street, Thirteenth Ward, over the valley, has been returned to the Council with a negative recommendation.

Baltimore, Md.—Proposals will soon be wanted for the construction of the Monroe Street Bridge, the plans, etc., for which are now being made.

Boston, Mass.—Plans for a bridge to be erected at Roxbury, over the tracks of the Fitchburg, to abolish the present grade crossing, have been submitted to the City Council for approval. The estimated cost of the bridge proper is placed at $78,142.

Dallas, Tex.—Contracts for the erection of bridges over Turtle Creek, at Lemmon Avenue and Peak Street, have been awarded to the George E. King Bridge Company.

Hancock, Md.—It is probable that the proposed bridge to be erected over the Potomac River, at this place, will soon be built, at a cost of $16,000.

Charlotte, S. C.—Reports say that the Charlotte, Columbia and Augusta Railroad will bridge its tracks at this place.

West Bay City, Mich.—The Saginaw River is to be bridged at this place by a $41,000 structure, the plans for which are now being prepared.

Bridges.—See our Proposal Columns for information regarding bridge construction at the following places: Augusta, Ga.; Zanesville, O.; Becket, Mass.; Helena, Mont.; Greenville, S. C.; Dublin, Ga.; Houston, Tex.; Philadelphia, Pa.

RAILROADS CANALS ETC.

Alton, Ill.—The Holmes syndicate has purchased the two street railroads here, and will build a new line, and operate all three by electricity.

Knoxville, Tenn—The Knoxville Street Railway Company is having surveys made under direction of W. C. Crozier, C. E., for an extension of its system to Lounsdale, about two miles.

STREET-WORK AND PAVING.

Westminster, Md.—The sum of $30,000 remains to be expended on improving the streets of this place.

Toledo, O.—Numerous street improvements are soon to be made in this city.

Montreal, Can.—The Sicilian Asphalt Paving Company has been awarded the contract for laying an asphalt sidewalk, one inch thick, on a 4-inch concrete foundation, at $3.23 a square yard, and 49 cents for the curb stone.

Salt Lake City, Utah.—Numerous streets of this city are to be repaved.

GAS AND ELECTRICITY.

Wilton, Iowa.—An electric light plant is to be established here at once.

Atlanta, Ga.—The Atlanta Electric Illuminating Company has been organized at this place with M. H. Atkinson for President, and a capital stock of $100,000.

Little Falls, N. Y.—A citizens meeting was held at this place October 4, for the purpose of looking into the advisability of organing a local electric light company with a view of utilizing the East Canada Creek for power. The meeting resulted in appointing the Hon. S. M. Richmond chairman of a committee to confer further in the matter with the Village Trustees.

Toronto, Ont.—Rumors say that this city will soon want bids for lighting the public streets by gas, as the electric lights are to be abandoned.

Leechburg, Pa.—An electric light plant is to be established at this place.

Berlin, Wis.—An electric light plant is to be established at this place, at a cost of $12,000.

Oscoda, Mich.—The people of this place have decided in favor of establishing an electric lighting plant.

Alexandria, La.—The question of establishing an electric light plant is being discussed.

Jamaica, N. Y.—A few weeks ago the Trustees of this village awarded a contract to the National Electric Manufacturing Company to light the village by electricity at the rate of $17.50 for each lamp of 32 candlepower. The Jamaica Gas Company wanted $24 per lamp. Three electric companies competed, and the National was the lowest bidder. On October 8 the gas company took an assignment of the contract. The assignor will put in the plant as provided for in the contract. The number of lamps will be 150 at starting, but 200 will be required to fully light the village.

Santa Fe, N. M.—The sum of $25,000 is to be expended on an electric light plant for this place.

Electric Railways.—New electric railways will be established, and improvements will be made to those already in operation at the following places: Olympia, Wash.; Lawrence, Mass.; Venice, Ill.; Sacramento, Cal.; Knoxville, Tenn.; Barnegat, N. J.; Philadelphia, Pa.; Eau Claire, Wis.; Cheyenne Park, Col.; Reading, Pa.; Schenectady, N.Y.; New Haven, Conn.

BIDS OPENED.

Albany, N. Y.—Superintendent of Public Works Hannan awarded the following contracts October 7: For superstructure of an iron bridge east of Lock No. 42, Erie Canal, near Herkimer, to Groton Building Co. at $2,070. For rebuilding culvert at Mechanicsville, to Cunningham & Riley, Sandy Hill, at $5.597.30. Improving 3,900 feet of canal wall near Mechanicsville, to same parties at $29.389. Improving wasteway north of Mechanicsville, to same parties at $5,708.75. Improvements to canal wall near Lansings waste weir to J. W. Whalen, of Whitehall, at $10,144.25. Improving 3,200 feet canal wall near Searles waste weir to Gardin & Dardes, of Fort Edward, at $18,011.50.

Brooklyn, N. Y.—Bids for two new boilers at the penitentiary were received by the Charities Commissioners October 4. They were as follows: R. A. Robbins, $2.497; Peter J. Donahue, $2,300; C. E. Jackson (for the Vertical Tube Boiler Company), $1,975; Smith Brothers (for the Brooklyn Iron Works), $2,475; Alexander Reid, Jr., $2,220; Donigan & Swift, $2,042; Blake & Williams, $2,087; Reene & Thomas, $2,200.

Ogdensburg, N. Y.—The E. H. Cook Company, of Rochester, N. Y., has secured the contract for heating the St. Lawrence State Hospital for the Insane, located at this place, the figure being $100,000.

Minneapolis, Minn.—The contract for 90 miles of the extension of the Soo from Hankinson, N. D., northwest, has been let to Linton & Co., 401 Nicollet Avenue, Minneapolis. Work will begin at once and pushed to completion as fast as possible.

GOVERNMENT WORK.

Washington, D. C.—The following proposals for the work specified were opened on the given dates by the Supervising Architects of the Treasury Department:

Pittsburg, Pa.—Low-pressure heating and ventilating apparatus of the Court House and Post-office at this place, opened October 8. Bidders: Schaefer & Becker, Cleveland, O., $75,230.30; Q. N. Evans Construction Co., New York, $76,209; Kelly & Jones Co., Pittsburg, Pa., $64,493; Crook, Horner & Co., Baltimore, Md., $59,867.43; Samuel I. Pope & Co., Chicago, Ill., $46,850; John Lyon, $61,075.66.

Eastport, Me.—Rolled iron beams, girders, etc., for the first story of the United States Custom House and Post-office at this place. Opened October 7. Bidders: Dearborn Foundry Co., Chicago, Ill., $880,000; Charles Raffen & Co, Chicago, Ill., $1,115,000.

NAVY DEPARTMENT.

Norfolk, Va.—For tile capping for the marine railway at the Navy Yard at this place. Opened October 8. Bidder: Holtzclaw Bros., Hampton, Va., $2,369.

Boston, Mass.—Pumping plant for the dry dock at the Navy Yard at this place. Opened October 8. Bidders: Holly Manufacturing Co., Lockport, N. Y., $156,400; Southwark Foundry and Machine Co., of Philadelphia, Pa., $149,890; Samuel I. Pope & Co., Chicago, Ill., $134,197.

Norfolk, Va.—For connecting the new pumps with the old dry docks at this place. Opened October 8. Bidder: Crook, Horner & Co., Baltimore, Md., $14,809.

Washington, D. C.—Bids were opened at the Navy Department, October 6, for the construction of the three steel tugs for the use of the navy, to cost not exceeding $35,000 each. The bids were as follows: Globe Iron Works Company, of Cleveland, O., for three tugs, $103,500, or at the rate of $34,500 for each, The Pusey & Jones Company, of Wilmington, Del., for one tug $45,000, for two tugs, $44,000 each, and for three tugs, $43,000 each. John H. Dialogue, of Camden, N. J., for three tugs, $99.900, at the rate of $33,300 for each. People's Machine and Boiler Works, of Baltimore, Md., for one tug, $34,500, and for two tugs, $34,250 each. Neafie & Levy, of Philadelphia, for one tug, $33.364, and for three tugs $100,000, or $33,333⅓ for each. The Samuel L. Moore & Sons Company, of Elizabeth, N. J., for one tug, $34,500, for two tugs $34,125 each, and for three tugs $34,000 each. Harrison Loring, of Boston, Mass., for three tugs $97,314, or at the rate of $32,438 each. The bid of Neafie & Levy is irregular in not being according to the plans of the Department.

Trenton, N. J.—The following proposals for the construction of a bridge over Stony Brook, at Mone's Mills, were opened by the Board of Chosen Freeholders, October 8: Iron work. New Jersey Steel and Iron Company, $1,800; Penn Bridge Company, Beaver Falls, Pa., $1,820; Wallis Iron Works, Jersey City, $1,985; Pittsburg Bridge Company, Pittsburg, $1,810; Millicken Brothers, New York, $1,875; Groton Bridge and Mfg. Co., Groton, N. Y., $1,806; Wrought Iron Bridge Company, Canton, O., $1,809. Mason work: James Duncan, $3,481; Chatten & Ewing, $2,489; A. M. Walton, $2,790; J. J. Johnston, $2,646. The contract was awarded to the lowest responsible bidder. The contract on the iron work was awarded to the highest bidder, on the grounds that such action would insure a complete job.

INDUSTRIAL.

Natural Bridge, Va. — The syndicate which recently purchased the park surrounding the Natural Bridge, will improve the property by building upon it a substantial stone hotel at a cost of $250,000. A feature of the improvement will be the illumination of the bridge and grounds by electricity.

Pullman, Ill.—S. S. Beman, architect, is preparing plans for a $250,000 repair shop for the Pullman Palace Car Co. It will be 500 feet square and furnished with steam heat and electricity.

PROPOSALS.

(Continued from page ii.)

U S. ENGINEER OFFICE, 18 W. SARATOGA Street, Baltimore, Md., September 30, 1890.—Proposals for completing the **SHIP-CHANNEL** leading to the harbor at Baltimore, will be received until noon of December 2, 1890, and then opened. The attention of bidders is invited to the acts of Congress approved February 26, 1885, and February 23, 1887, vol. 23, page 332, and vol. 24, page 414, Statutes at Large. For information, apply to WM. P. CRAIGHILL, Colonel Corps of Engineers, U. S. A. 22

OFFICE OF LIGHT-HOUSE INSPECTOR, Third District, Tompkinsville, N. Y., Post-Office Box 2128, New York, N. Y., October 9, 1890.—Proposals will be received at this office until 1 o'clock P. M. on TUESDAY the 11th day of November, 1890, for furnishing to the Light-House Establishment such **IRON BUOYS** and appendages, mooring-chain, and bells, as may be required during the fiscal year to end June 30, 1891. The articles to be furnished embrace nun, can, bell whistling and ice buoys, shackles, swivels, mooring-chain, ballast balls, iron and stone sinkers, etc., all of which are enumerated in the specifications attached to the form of bid, which may be obtained on application to this office. Contracts will be awarded on each item separately, and bidders are required to state the time when they will agree to deliver the articles. The right is reserved to reject any or all bids, to strike out any item or items in the specifications, and to waive any defects. HENRY F. PICKING, Captain, U. S. N., Light-House Inspector, Third District.

WATER-WORKS, Keithsburg, Ill.—Proposals are wanted until October 23, for constructing a standpipe system of water-works. Address J. L. Noble, Mayor, as above.

BRIDGE, Augusta, Ga.—Proposals are wanted until October 20, for the construction of a bridge to span the Savannah River. Address Grant Wilkins, 9½ Peachtree Street, Atlanta, Ga.

CITY HALL, Keithsburg, Ill. — Proposals are wanted until October 23, for the completion of a city hall for said city. Address J. L. Noble, Mayor, as above.

PILE WORK, Savannah, Ga. — Proposals are wanted until October 20, for constructing training walls in the Savannah River. Address O. M. Carter, First Lieut. Corps of Engineers, U. S. A,

WATER POWER, Winnipeg, Manitoba.—Proposals are wanted until October 15, for the construction of the work necessary to make available the water power of the Assiniboine River. Address Joshua Callaway, Chairman Special Water Power Committee, as above.

BRIDGE, Zanesville, O.—Proposals are wanted until November 11, for the construction of a bridge across the Muskingum River. Address J. A. Knight, Auditor, as above.

STREET WORK, Jersey City, N. J.—Proposals are wanted until October 20, for the improvement of Woodward Street. Address E. A. Dugan, Chairman of Streets and Sewers, as above.

SEWERS, Jersey City, N. J.—Proposals are wanted until October 20, for the construction of the Hopkins Street Sewer. Address E. A. Dugan, Chairman of Streets and Sewers, as above,

BRIDGE, Becket, Mass.—Proposals are wanted until October 16, for the construction of an iron bridge at this place. Address J. A. Hunt, as above.

RESERVOIR, Philadelphia, Pa.—Proposals are wanted until November 7, for the construction of a reservoir. Address Louis Wagner, 1321 Filbert Street, as above.

CAST-IRON PIPES, Philadelphia, Pa.—Proposals are wanted until October 16, for cast-iron pipes, special castings, etc. Address Louis Wagner, 1321 Filbert Street, as above.

LAVATORY BUILDING, Boston, Mass.—Proposals are wanted until October 20, for building a woman's lavatory at Charlesbank. Address Park Commissioners at Boston, Mass.

HOSPITAL, Atlanta, Ga.—Proposals are wanted until October 20, for labor and material required in constructing the buildings for the Grady Hospital. Address Jacob Elsas, Chairman Building Committee of Grady Hospital, as above.

Building Intelligence.

BOERNE, TEX.—Dr Barpitz can furnish information regarding a $100,000 hotel to be built here.

CADILLAC, MICH. — Lumber mill, cost, $50,000; o, Cobb, Mitchell & Co; b, not let.

Saw mill; cost, $10,000; o, F A Diggins & Co; b, not let.

CAMBRIDGE, MASS. — Howard st, fr dwell; cost, $12 200; o, D W Chamberlain, a, Chamberlain & Austin; b, R L Snow.

CHATTANOOGA, TENN.—A hotel to cost $250,000 is to be erected on Cameron Hill in this city.

CINCINNATI, O.—Fairfield and Lincoln avs, 2½-story br dwell; cost, $15,000; o, Mrs Hannah Marks; c, Jas Griffith & Sons.

Poplar, near Linn st, 3-story br slaughter house; cost, $8,000; o, Gottlieb Earhart.

CLEVELAND, O.—Wood and Lake, br and st apartment house; cost, $18,000; o, Robt Blee; a, Lehman & Schmitt; b, McMullen & Collister.

Bolivar, Sheriff and Huron, market bldg; cost, $300,000, o, Stock Co; a, as above; b, not let.

DALLAS, TEX.—The Oriental Hotel to be erected at this place will cost $600,000.

GALVESTON, TEX.—Av I bet 20th and 21st sts, electric street railway station; cost, $15,000; o, Wm H Sinclair, President Galveston Street Ry. Co; a, N J Clayton & Co.

GENEVA, ILL.—Burnham & Root, architects, Chicago, Ill, have the plans for a new court-house for this place. Contract not let yet.

HARVEY; ILL.—Charles Denham, of the Harvey Land Association, and others, are interested in the construction of a new hotel, to cost $25,000.

MINNEAPOLIS, MINN.—It is stated that a proposition was closed October 6 by which a new theater will shortly be opened in this city, at a cost of $75,000. Thomas Low, the street railway builder, has agreed to build the structure.

MINNEAPOLIS, MINN. — The Franklin Av M E Church will build a new church at Portland av and 22d st. Reputed cost, $80,000. Dr R N McKaig, pastor, taking active interest in plans.

MONTCLAIR, N. J.—Fullerton av, cor Plymouth st, addition to Congregational Church, and chapel for the same church on the adjoining lot; cost, $30,000 each; o, Congregational Church Society; a, J C Cady, of New York; b, not let.

NEW ORLEANS, LA.—A project is on foot to build a $1,000,000 resort hotel here; Mayor Shakspeare can give information.

NEWTON, MASS.—Prince st, fr dwell; cost, $8,000; o, Geo P Howlett; a, C H McClare; b, Briggs Bros.

SAGINAW, MICH. — S Franklin, 5-story and basement furniture store and offices; cost, $20,000; o, J L McCormack; a, F W Hollister; b, Wm Meuller.

SALEM, MASS.—A fire engine house, to cost $24,000, is to be erected in this city.

SARATOGA, N. Y.—A large bathing establishment will be erected here over the old Putnam Spring.

BUILDING INTELLIGENCE.

SIOUX CITY, IOWA.—Cor Douglas and 12th sts, stone Episcopal church; cost, $50,000; o, St Thomas Society; a, Henry M Congden; b, not let.

SOUTH BEND, IND.—Corner Notre Dame and Jefferson sts, 2½-story br and s dwell; cost, $10,000; o, Mrs M Coquillard.

ST. LOUIS, MO.—Olive st and Grand av, br hotel; cost, $18,500; o, Harriet Beers; b, A E Cook.

S w cor Leonard av and Locust st, br car-house; cost, $7,000; a, Mo R R Co; a, Milburn & Rich.

Finney av and Sarah st, br dwell; cost, $12,000; o, J E McGueness; b, T C Higgins.

Finney ave and Sarah st, br dwell; cost, $8,000; o and b, same as above.

9th and Arsenal sts, br stock house; cost, $30,000; o, A B Bwg Ass'n; b, sub-let.

N w cor 23d and Montgomery sts, br store and ten; cost, $7,500; o, Allenberg Bros; b, Wm Paul.

S w cor 12th and McGirk sts, br office bldg; cost, $7,000; o, Louis Obert; b, H H Schumaker.

S e cor Spring and Garfield avs, br church; cost, $10,000; o, First German Congregational Church; b, sub-let.

ST. PAUL, MINN.—Plans are being prepared for a new hotel at White Bear Lake, to cost $100,000. J D Ramaley will build it.

A permit has been issued to A H Wilder for the inside alterations in the 2-story br bldg on E 4th st, between Jackson and Sibley; estimated cost, $10,000.

Robert nr Delas, 3-story br and s stores and dwell; cost, $16,000; o, C F Meyer.

Case nr Arkwright, 3-story br stores; cost, $30,000; o, John Dale, President, St Paul Building Improvement Company.

Iglehart nr Fisk, 2 2-story br dwells; cost, $10,000; o, Burton & Ford.

TOMAHAWK, WIS.—A hotel, to cost $40,000, is to be erected at this place.

WATERBURY, CONN.—The School Committee has recommended that a new school building be provided, and it is understood that steps will be taken toward that end.

WILLIMANSETT, MASS. — br factory, 30x40; o, Springfield Facing Company; a, G P Alderman, of Holyoke.

WOOSTER, O.—Br business bldg; cost, $12,000; o, Jacob Frick; a, H. B Smith; b, not let.

WORCESTER, MASS.—Pleasant st, br theater; cost, $10,000; o, R C Taylor; a, Cutting & Forbush; b, day work.

Buildings.—There is nothing over $7,000 in value to report at the following places: Geneva, N. Y.; Binghamton, N. Y.; South Bethlehem, Pa; Pottstown, Pa.; Harrisburg, Pa.; Wilkes Barre, Pa.; Allegheny, Pa.; Poughkeepsie, N. Y.; Galveston, Tex.; Waco, Tex.; Madison, Wis.; Zanesville, O.

SPECIAL OFFERS.

DOUBTLESS many of our subscribers have a friend who thinks of subscribing to THE ENGINEERING AND BUILDING RECORD for the coming year, and as every paper, however successful it may be, desires to increase the number of its subscribers, the following offers are made, to hold good during October, November and December:

First.—Any present subscriber can have his subscription extended one year by sending us $7.25, accompanied by the name and address of a new subscriber who is not now buying THE ENGINEERING AND BUILDING RECORD of a newsdealer.

Second.—Any present subscriber can, under the conditions mentioned in first offer, have his own yearly subscription for $2 by sending us, with his renewal, two *new* names and $10, or for $1, by sending three new names and $13.

THE ENGINEERING AND BUILDING RECORD,
P. O. Box, 3037. 277 Pearl Street, New York.

TABLE OF CONTENTS.

EDITORIALS:

Improvement of Public Highways 307
Politics in Municipal Engineering 307
Steamship Fire-Room Ventilation 307
Prize for Water-Works Project 308
Designs for the Fine Arts Building at New York 308
The Pennsylvania Ship Canal 308
American Institute of Architects 308
The Dunderberg Spiral Railroad 308
Electric Light in the Suez Canal 308
Cement at Stettin, Germany 308
Obituary—Personal—Our Architectural Illustrations 308

Odorless Excavating Apparatus 318
Direct Pressure Water Supply 318
Building Intelligence xi-321-322
Contracting Intelligence 319-320
Proposals i-ii-321

IMPROVEMENT OF PUBLIC HIGHWAYS.

A NUMBER of States in the Union seem to be waking up at last to the necessity of having better country roads and a better system of making and repairing them, a matter in which THE ENGINEERING AND BUILDING RECORD has taken great interest, as is shown by the numerous articles upon the subject to be found in its columns during the past few years.

The importance of securing skilled engineering supervision, both for the construction and maintenance of highways, instead of leaving them to the tender mercies of the road overseers or highway commissioners, as they are severally entitled, in different localities, is patent to anyone who has given the subject any attention or thought. The engineer should not be an inexperienced one—still less a mere country surveyor—who, from his ignorance of the work of construction, would be easily hoodwinked by contractors, or over-ridden by the Board of Supervisors or other authority by whom he may be employed. One of the worst features of the old system is permitting road taxes of any person to be worked out by his day labor, or that of his teams or hired men, a practice which has frequently been condemned by many writers. Nothing could be more wasteful in labor or more inefficient.

Ohio has taken the lead, at least amongst the Western States, in requiring road taxes to be paid in cash, and strong efforts are being made both in Pennsylvania and Rhode Island to have laws passed abolishing the present practice of working them out. In Georgia and Alabama the necessity of highway improvement is generally acknowledged, and organized efforts are being made to obtain the necessary legislation for this purpose, though the advantages of securing the services of experienced engineers seem hardly yet to be understood or appreciated.

In Tennessee, however, as a consequence of the agitation of the subject, Dr. Olin H. Landdreth, of Vanderbilt University, who has for some years given to it much thought and study, has prepared for the consideration of the Tennessee Road Congress a bill for a new highway law for the State, in which the necessity for experienced engineering superintendence is given prominence. The bill seems to have been drawn with much skill and care. The practice of engaging the services of engineers for the improvement of roadways in different parts of New Jersey is also coming into more extended use. Taken altogether, there is every indication that the subject is, at last, to receive intelligent consideration from the proper authorities, and that something substantial will be done in the way of road improvement and maintenance.

POLITICS IN MUNICIPAL ENGINEERING.

THE New York daily press recently noticed the discharge of two employees by the Dock Commissioners, on the complaint of the Chief Engineer of the Dock Department, for inefficiency. The discharged men have set up a plea that they are members of the Grand Army, and have engaged an attorney to demand their reinstatement on this ground, compelling the Commissioners to refer the matter to the Corporation Counsel for an opinion. They, of course claim that they are not inefficient; but their interested statements would weigh little compared with the evidence of a skilled and reputable engineer like the present head of the engineering corps of the Dock Department.

Incompetent men and shirks are, naturally, to be found amongst the veterans as well as in all other classes, and whilst the tendency to give to men who risked their lives for the country during the war, a preference in public employment is defensible, no sentimentality should stand in the way of their prompt discharge if unable to properly fulfill their duties; still less if they presume upon their membership in the Grand Army to neglect and shirk their work.

This is only another phase of the crying evil of political management of public works in most of our large cities. The engineer is held responsible for the economical and efficient management, as well as for the quality of his work, and yet is often compelled to employ men, thrust upon him by party tricks and ward politicians, among whom the available places are parcelled out. If he attempts to discharge them for inefficiency, or even for worse cause, he is thwarted by the political "pull" at once exerted in their behalf. When, as was the case under the previous Croton Aqueduct Commission, such protection is extended to inspectors, the results must necessarily be disastrous. It may be too much to expect the near approach of an entire separation of politics from the expenditure of money for public works, but at least the responsible engineer, who has so much to do with the life and health of the community, should not be deprived in any degree of his power of removing his subordinates for cause, no matter to whose influence they may owe their appointments.

STEAMSHIP FIRE-ROOM VENTILATION.

FROM England comes a report that *The Lancet* recently sent a special reporter on board some ships to look into the conditions under which stokers work, the result being an article headed "Floating Death Traps," and descriptive of a state of things which an English contemporary hopes is confined to few vessels.

Unfortunately, *The Lancet's* article is not at hand and its exact nature, therefore, a matter of speculation. It is pretty safe to assume, however, that the article deals with the almost intolerable temperatures found in steamship fire-rooms, and the directly related subject of ventilation. From the information made public from time to time, of the exacting character of the work performed by firemen aboard a large number of steamships, and of the distressing conditions under which this work must be carried on, the general conviction can scarcely have been escaped that the problem of how to maintain a fairly comfortable atmosphere for these men to work in has received but scant attention. It is not to be expected that with blazing furnaces in necessarily cramped spaces temperatures much below 100° Fahr. can be secured, but, on the other hand, there is little reason why they should range from 20 to 40 degrees above this point. And yet such high temperatures are by far more common than ship-owners are willing to admit. That they can be avoided has been conclusively shown.

The whole matter, as pointed out in an earlier issue, is one of expense, and comparatively trifling expense too; but there is little hope of having the evil remedied so long as there is nothing to compel ship-owners to avail themselves of the existing means of bettering the fireman's condition, and so long as men can be found to fill the places vacated by others.

PRIZE FOR WATER-WORKS PROJECT.

About sixteen years ago the King of Belgium instituted an annual prize of 25,000 francs with a view of encouraging intellectual works upon various subjects. The prize which is to be the object of the international competition for 1893 will be awarded for the best work on the means of procuring for large cities, and particularly the city of Brussels, an abundant supply of the purest drinkable water, provision being made for the anticipated increase of population. Both manuscripts and printed works will be admitted for competition. The new edition of an existing work will only be receivable if it includes considerable modifications and developments published in the years 1889, 1890, 1891 or 1892. The works may be written in French, Flemish, English, German, Italian or Spanish. Foreigners desiring to compete will have to forward their works before the 1st of January, 1893, to the Minister of Agriculture. Industry and Public Works, in Brussels. Any manuscript work for which the prize may be awarded must be published during the course of the following year. The decision upon the competition will be given by a jury appointed by His Majesty the King of the Belgians and composed of seven members—three Belgians and four foreigners of different nationalities.

DESIGNS FOR THE FINE ARTS BUILDING AT NEW YORK.

The following members of the jury appointed to select plans for the new fine arts building at New York, met on the 14th, inst., in the rooms of the American Fine Arts Society, William M. Chase, President of the Society of American Artists; Russell Sturges, President of the Architectural League; Howard Russell Butler, President of the American Fine Arts Society; E. D. French, President of the Art Students' League, and Edward H. Kendall, Chairman of the Committee on Site and Plans. The Society of the American Artists, the Architectural League of New York, and the Art Students' League, which, in conjunction, compose the American Fine Arts Society, issued a circular some time ago, which was sent to a number of architects asking them to compete for plans of a new building, to be known as the Fine Arts Building, and in which each society was to occupy a specified part.

Three plans were selected at the recent meeting, out of thirty-one that were submitted in response to the circular, as coming within the requirements of the society and being particularly good. These will be returned to the architects, who will have sixty days to perfect them under the instructions of the society, when one of them will be selected for the building.

The three successful architects whose designs were thus chosen are, H. J. Hardenberg, of No. 10 West Twenty-third Street., with associate artists Walter C. Hunting and John C. Jacobsen; second design, Edmund B. Wells, of No. 111 Broadway, and the third by Babb, Cook & Willard, of No. 55 Broadway, all of New York.

THE PENNSYLVANIA SHIP CANAL.

According to Pittsburg reports the surveys of the Pennsylvania ship canal are practically finished, and the commission appointed by the Legislature will ask the State to complete the canal.

The commission find the scheme feasible, and favor a route along the Beaver River to Lake Erie. The commission, as a body, have not yet given any figures as to what it would cost to build the canal, but as individuals they have admitted that it would cost as much if not more than the Welland canal, which connects Lake Erie and Lake Ontario.

The Board of Brooklyn Bridge Experts held three meetings during the past week. One meeting was given over to the continuation of the examination of the plans. At the other two, Messrs. Charles E. Emery and W. E. Worthen were allowed to explain their ideas.

THE DUNDERBERG SPIRAL RAILROAD.

T. L. and H. J. Mumford, the controllers of the Mauch Chunk Switchback Railroad, have for several years thought of building a similar railroad and a hotel on one of the Highlands of the Hudson. In pursuance of this idea, experimental surveys were made on all the mountains in the neighborhood of West Point. The Dunderberg was the last to be examined, and was at once selected on account of its magnificent views and owing to its being the most accessible, and having, in addition, the advantage of being nearer the metropolis. As a result of this project a spiral railway is now being built up the side of the mountain. The cars will be drawn up by cable, the arrangement used being said to be perfectly safe. There will be two planes, one 600 feet in elevation, and the other ascending 400 feet more. At the top of each of these planes will be a stationary engine, which will perform the work of hauling up the trains. The cars will return to the foot by a spiral gravity railroad over ten miles in length, of an extremely circuitous route and commanding over six or eight entirely different views of the Hudson and surrounding country. On the extreme top will be erected a hotel. The Hudson River Improvement Company is carrying out the project.

ELECTRIC LIGHT IN THE SUEZ CANAL.

The regulations for the use of the electric light came into operation in March, 1887, and during the remainder of that year (according to statistics given in the recent British consular report from Port Said), the number using it was 394. In 1888 the number rose to 1,611, and last year reached 2,445. The average time of transit has also been considerably shortened. In 1886, it was 36 hours; in 1887, 33 hours, 58 minutes; in 1888, 31 hours, 15 minutes; and in 1889, it had been reduced to 25 hours, 50 minutes. The average time for using the electric light in 1889 was 22½ hours. The shortest time taken by a steamer in the transit of the canal in 1889, was 14¾ hours, which is 10 minutes less than the fastest passage on record previously.

AMERICAN INSTITUTE OF ARCHITECTS.

The twenty-fourth annual convention of the American Institute of Architects will be held at the Arlington Hotel, Washington, D. C., beginning October 22, 1890. The following is the order of proceedings and general information:

The meetings will be held in the Arlington Hotel, the rate being reduced from five to four dollars per day for the occasion. It is desirable, so as to expedite business and pleasure, to have all members stop at the same hotel.

The Board of Directors will meet on Tuesday afternoon, October 21, at 4 o'clock.

Afternoon Session, Wednesday, October 22, 4 o'clock.—Roll call. Address of welcome by the Hon. J. W. Douglass, President Board of Commissioners, District of Columbia; address by R. M. Hunt, F. A. I. A., President of the American Institute of Architects; reports of the Board of Directors, Treasurer, Committees and Chapters; the Trustees of the Corcoran Gallery of Art especially open, and invite members of the Institute and their ladies to the Gallery in the evening between 8 and 9 o'clock; the Cosmos Club will receive members after 9 o'clock.

Morning Session, Thursday, October 23, 10 o'clock.—Reports of committees, etc.; papers; Sketch of the History and Status of the American Institute of Architects, A. J. Bloor, F. A. I. A.; Foundations of Kansas City Hall, S. E. Chamberlain, F. A. I. A.; Science of Æsthetics, Henry Rutgers Marshall, F. A. I. A. Afternoon trip to Mt. Vernon and oyster lunch on the boat, given by the Washington architects. The "Charles Macalester" will leave the Seventh Street wharf promptly at 3 o'clock P. M.

Morning Session, Friday, October 24, 10 o'clock.—Election of officers; final business before the Convention; adjournment, followed by a visit to the White House. The afternoon, visitors can devote to sight-seeing in the city, as follows:

Mr. Edward Clarke will meet in his office in the Capitol at 3 o'clock all who wish to see that building. Mr. J. H. Windrim will receive at 2 o'clock, in the office of the Supervising Architect, Treasury Department, all who wish to examine the Treasury and Supervising Architect's office. Mr. G. Brown Goode will meet, in the reception-room of the National Museum at 2 o'clock, all who wish to see that building. Mr. Adolph Cluss will await in the reception-room, at 3 o'clock, those who wish to visit the Patent Office.

Other members of the Washington Chapter will hold themselves in readiness to accompany parties of visitors to any point of interest about the city which they may desire to see. The railroads will give a return rate for one-third the regular fare, in accordance with circular already issued by the Secretary. The architects who attend the convention will confer a favor on the Committee of Arrangements by signing the Register of the convention, which will be in the office of the Arlington Hotel, immediately upon their arrival.

CEMENT AT STETTIN, GERMANY.

According to a recent report by Andrew F. Fay, United States Consul at Stettin, Germany, there are in the neighborhood of that city six manufactories of cement—viz.: Stettin Portland Cement Company, the Star Portland Cement Company, the Bredow Portland Cement Company, the Pomerania Industrial Verein, all located at Stettin; the Mercun Cement Company, located at Jatsnick; the Gristow Cement Company, located at Gristow.

The total output of these six corporations amounts to about 1,000,000 barrels per annum; each barrel contains 170 kilograms (375 pounds). About 750,000 barrels are sold for domestic use, and the remaining 250,000 barrels are exported to the following named countries: Norway, Sweden, Denmark, United States, Russia, Austria (very little), Brazil, and Australia. The exports to Russia are diminishing very fast, inasmuch as the product of the Russian manufacturers is said to be very good.

The cost of the manufacture, including labor, is about 23 cents per 100 pounds. It may be a few cents more or less, according to the prevailing conditions and the year; however, the cost seldom exceeds that figure. The industry is in a prosperous condition.

OBITUARY.

Edward Balbach, Sr., the founder of the smelting works of E. Balbach & Son, at Newark, N. J., died on October 14, in his 87th year.

Commander Charles L. Huntington, of the U. S. Navy, died at Brooklyn, N. Y., on the 14th inst. He was recently detached from the command of the "Pensacola" on account of ill health.

Prof. Austin Phelps, of Andover, died at his Bar Harbor, Me., cottage on October 13, after a long illness. He was born in Brookfield, Mass., in 1820, and was graduated in 1837 at the University of Pennsylvania.

John R. Mawle, of Cookshire, P. Q., a civil engineer who assisted in the laying out of the Upper Coos, N. H., Railroad, and who was afterward in the service of the corporation, died recently at Dartmouth, N. H., aged 26.

Thomas Franklin Hoxey died on the 14th inst. at Paterson, N. J. He was born at Paterson, March 5, 1841, and was the oldest son of General Thomas D. Hoxey. He was an engineer by profession, and engaged most of his life in contracts for railroad building, and the construction of reservoirs for the Paterson Water-Works and the improvement of streets and roads.

Col. Herbert A. Hascall, U. S. A., retired, died in Chicago, on the 14th inst., after a long illness, aged 76. Colonel Hascall earned a reputation as a fearless officer in Florida during the Seminole outbreak, was in Utah during the Mormon troubles, and saw much active service in the Civil War. He was at one time professor of mathematics at West Point.

PERSONAL.

Martin Aulls & Follett, civil and consulting engineers, are the successors of Lowrie & Aulls, of Denver, Col.

Y. Foster Crowell, M. Am. Soc. C. E., has been called by the Government to Hayti to examine the question of local railroad matters.

F. Harvey Smith, C. E., formerly in the City Engineer's Department at Springfield, Mass., is now engaged on the sewerage system at Talladega, Ala.

Clift. Wise, Chief Engineer of the Minneapolis Street Railway Company, has severed his connection with that company. Mr. Wise has accepted a position with a new electrical company, and will have his office in New York.

D. M. Scott, M. E., who has lately been connected with the Detroit Heating and Lighting Company, at Chicago, has associated himself with the National Hot Water Heater Company, and will make his headquarters at their Chicago office.

ENGINEERING SOCIETIES.

A meeting of the Engineering Association of the Southwest was held at Chattanooga, Tenn., on October 10 and 11.

The Committee on the "Cause of the Setting of Cement," appointed at the Louisville meeting, submitted a report on the chemical relations involved in the process of setting, prepared by Dr. W. L. Dudley, of Vanderbilt University. The final report will be presented at a later meeting.

Mr. James A. Fairleigh, engineer in charge of the construction of the new Tennessee River Bridge, at Chattanooga, gave a detailed account of that structure, illustrating his remarks by elaborate drawings and maps. The subject was discussed at length by Mr. Thacher, of Louisville; Mr. Whinety, of Cincinnati; Colonel Barlow, of Nashville; Captain Chamberlain, of Chattanooga, and Professor Landreth, of Vanderbilt University.

Messrs. Joseph C. Guild and William Bowron, both mining engineers, of Chattanooga, entertained the visiting members with explanations of the geology and the mineral deposits of the Chattanoogo district, and illustrated their remarks by references to a very large and complete map of the Chattanooga mineral district, prepared for the Chamber of Commerce.

HOUSE OF REV. WILLIAM LAWRENCE, BAR HARBOR, ME.—ROTCH & TILDEN, ARCHITECTS, BOSTON, MASS.

An amendment to the constitution of the association was proposed reporting a change of the name of the association to the "Engineering Association of the South." The amendment will be discussed at the annual meeting at Nashville, Tenn., in November, and then go to the membership for ballot.

The Boston Society of Civil Engineers held a regular meeting on Wednesday evening, October 15, at 7.30 o'clock, with Vice-President William E. McClintock in the chair; S. E. Tinkham, Secretary, and about 60 members and visitors present.

The following were elected members: Charles F. Baxter, Boston; Frank A. Bayley, Cambridge, Mass.; Charles A. Bowman, Winchester, Mass.; Benjamin F. Goodnough, Brookline, Mass.; Ernest G. Hopson, South Framingham, Mass., and Arthur C. Moore, Sturbridge, Mass.

E. S. Dorr exhibited and explained a diagram for determining approximately the sizes of sewers.

Albert F. Noyes, referring to a map, briefly recounted the reasons for building an addition to the Newton, Mass., Water-Works, rendered necessary from the fact that certain elevated points in various sections of the city are without a sufficient water supply and pressure for fire purposes, etc.; and H. D. Woods gave a detailed description of the construction of the covered reservoir and filtering conduit now being built for the above works, illustrating by colored drawings.

The last paper of the evening was by H. H. Carter, who spoke on the settlement of large embankments, having special reference to the one between Squantum and Moon Island, in Boston Harbor, and illustrating with drawings.

The above papers were informally discussed by various members.

A regular meeting of the American Society of Civil Engineers was held October 15, Vice-President Alphonse Fteley presiding.

Past President William E. Worthen presented a paper on "Steam Heating," which elicited supplementary remarks by J. B. Francis, and discussions by C. E. Emery, W. J. Baldwin, A. Fteley, G. H White, H. W. Brinckerhoff, A. G. Brinckerhoff, F. W. Skinner, and others.

There was an attendance of about 70.

MEETINGS OF ENGINEERING SOCIETIES.

The American Society of Civil Engineers holds its r gular meetings on the first and third Wednesday in each month, at the House of the Society, 127 East Twenty-third Street, New York.

The Boston Society of Civil Engineers holds its regular meetings at the American House, Boston, at 7.30 P. M., on the third Wednesday in each month.

The Western Society of Engineers holds its regular meetings at its hall, No. 67 Washington Street, Chicago. at 7.30 P. M., on the first Wednesday in each month.

The Engineers' Club of St. Louis holds regular meetings in the club's room, Laclede Building, corner Fourth and Olive Streets, St. Louis, on the first and third Wednesdays in each month.

The Engineers' Club of Philadelphia holds regular meetings at the House of the Club, 1122 Girard Street, Philadelphia.

The Engineers' Society of Western Pennsylvania holds regular meetings on the third Tuesday in each month, at 7.30 P. M., at its rooms in the Penn Building, Pittsburg, Pa.

The Engineers' Club of Cincinnati holds its regular meetings at 8 P. M. on the third Thursday of each month at the Club rooms, No. 24 West Fourth Street, Cincinnati.

The Civil Engineers' Club of Cleveland holds regular meetings on the second Tuesday of each month, at 8 P. M., in the Case Library Building, Cleveland. Semi-monthly meetings are held on the fourth Tuesday of the month.

The Engineers' Club of Kansas City meets in Room 200, Baird Building, Kansas City, Mo., on the second Monday in each month.

The Engineering Association of the Southwest holds regular meetings on the second Thursday evening of each month at 8 o'clock, at the Association headquarters, Nos. 63 and 64 Baxter Court, Nashville, Tenn.

The Civil Engineers' Society of St. Paul meets at St. Paul, Minn., on the first Monday in each month.

The Montana Society of Civil Engineers meets at Helena Mont , at 7.30 P. M., on the third Saturday in each month.

The Civil Engineers' Association of Kansas holds regular meetings on the first Wednesday in each month at Wichita, Kan.

The New England Water-Works Association holds quarterly meetings in Boston at Young's Hotel.

The Canadian Society of Civil Engineers holds its regular meetings on each alternate Thursday, commencing with the 9th of October, at the House of the Society, 112 Mansfield Street, Montreal.

The Engineering Department of the Brooklyn Institute, Brooklyn, holds regular meetings, at 8 P. M., on the third Tuesday of each month. Until the Institute building is repaired, the meetings will be held in the rooms of the Young Men's Christian Association Building, 502 Fulton Street.

The convention of the American Institute of Architects will be held in Washington, D. C., beginning on October 22, and continuing until the business has been completed.

PHILADELPHIA CHAPTER OF THE AMERICAN INSTITUTE OF ARCHITECTS.

At a meeting of the Philadelphia Chapter, held Tuesday evening, October 14, the following were elected officers for 1890–91: T. P. Chandler, Jr., President; George C. Mason, Jr., First Vice-President; Lindley Johnson, Second Vice-President; Amos J. Boyden, 413 Walnut Street, Secretary; William C. Prichett, Jr., Treasurer; Isaac Pursell, T. Roney Williamson, other members of Executive Committee; Frank Miles Day, Librarian; Frank E. Meade, Assistant Librarian; Frank Miles Day, Wilson Eyre, Jr., Walter Cope, Amos J. Boyden, John Stewardson, Education Committee. The Chapter now has 75 members.

English capitalists are reported to have obtained options on about twenty sewer pipe manufactories, mostly at Akron, Columbus and other Ohio towns, for the purpose of forming a sewer pipe trust.

One of the results of the rapid growth of incandescent electric lighting is the increase in the price of platinum. The metal i[illegible] in every incandescent lamp, making connecti[illegible]bon filaments.

A BIRMINGHAM SHIP CANAL.

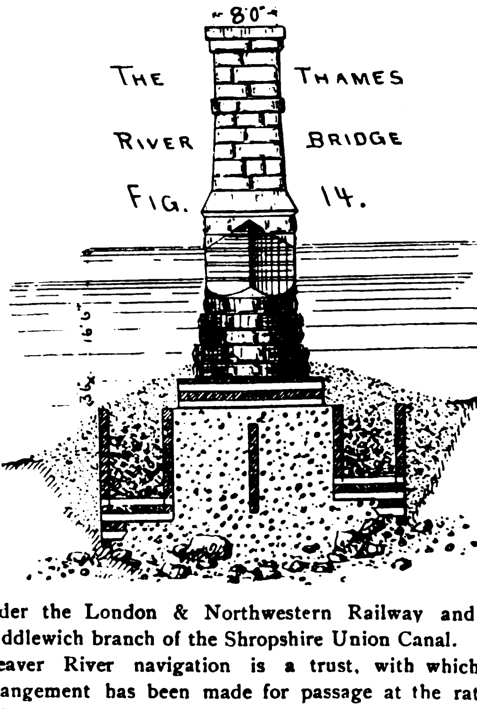
The demand of the traders of Birmingham and the midlands for better and cheaper communication with the sea has lately shown signs of revival, according to the London *Times*, in consequence of "the measure of revision which the Board of Trade offer in their newly published report on railway rates falling so far short of the requirements of midland traders that they begin to despair of relief through legislation, and they are, therefore, turning once again to the consideration of the obvious alternative, namely, improved water communication." After some consideration of rival routes, the one toward Liverpool has been adopted, passing through the heart of the Black Country to Wolverhampton, and thence, in a line nearly due north, through the potteries to Stoke-on-Trent. From this latter town it passes in a northwesterly direction through Kidsgrove and Wheelock to Winsford, where it joins the Weaver. Between Birmingham and this point of junction the distance is 61 miles, and the Weaver navigation extends for another 20 miles to the Mersey, which it strikes at Weston Point, 15 miles from Liverpool. The canal is to be 72 feet in minimum width and capable of accommodating sea-going vessels of 300 tons, or barges of 400 tons.

As the scheme is in the hands of a strong provisional committee of well-known local men, and is favored not only by the commercial classes of Birmingham and its vicinity, but by the land-owners along the proposed route, by the Manchester Ship Canal Co., and by the Mersey Docks Board, it seems likely to be carried out. On the other hand, of course, it must reckon on the determined opposition of the railroad companies, whose interest it so seriously threatens, and the costs of promotion, therefore, are likely to be heavy.

The estimated cost, including promotion, is not expected to exceed £3,000,000, and the promoters calculate that a charge of four shillings per ton on the carriage of 2,000,000 tons of merchandise yearly would earn 10 per cent. on the capital. The traffic over a single canal connected with Birmingham amounted during 1885 to 7,327,269 tons, including merchandise, 972,749; pig iron, 586,434; coal, 3,333,865: iron-stone, 495,912; sand, 115,791; lime and limestone, 140,828; road materials and manure, 525,249; bricks, 460,359, and in the same year 1,499,795 tons of goods were carried into Birmingham by rail and 263,660 tons were taken out. Therefore the amount of traffic does not seem excessive, and as the freight charge on scrap iron from Birmingham to Liverpool, apart from terminal charges, is 10 shillings per ton, the charge of four shillings for carriage seems reasonable.

The carriage of the above estimated merchandise is to be done by the company, which proposes purchasing a fleet of 30 steam barges, each carrying 250 tons, and 30 other barges, carrying 300 tons, to be towed, and a speed of eight or nine miles is expected, so that it will be possible to traverse the distance from Liverpool to Birmingham in 24 hours. It is estimated that each pair of barges will make about 70 trips per annum, giving a gross carrying power of 1,155,000 tons, in addition to which will be the traffic carried in private boats.

The levels of the canal, commencing at Birmingham at an elevation of 453 feet above the sea, fall to tide water at the emptying of the Weaver into the Mersey. This fall will be overcome by the balanced caissons or hydraulic lifts designed by Mr. Clark, and in such successful use on several European canals. The first lift at Wolverhampton will overcome a difference of level of 60 feet, with one or two heavy cuttings between that place and Birmingham. At Trentham there will be a tunnel 900 to 1,200 feet long through a ridge. From this the new canal will run parallel to the Trent & Mersey Canal, which, in a distance of seven miles has 25 locks, the passage of which occupies the best part of a working day. In the new canal this fall will be overcome by four lifts. At the junction with the Weaver River navigation, at Winsford, the descent will be made in two stages, as it will be necessary to go under the London & Northwestern Railway and the Middlewich branch of the Shropshire Union Canal. The Weaver River navigation is a trust, with which an arrangement has been made for passage at the rate of eight pence per ton, or eight mills per ton mile, said to be favorable terms. The locks on the Weaver are 220 feet long, 42 feet wide, with 15 feet of water on the sills. It is stated that the sides and bottom of the new canal are to be lined with 9 (?) feet of concrete, to withstand the wash of the passing boats, and that the width of 72 feet was adopted instead of 60 also on account of the waves generated by the passing tugs.



THE THAMES RIVER BRIDGE.*

Abstracted from the recently published report of Alfred P. Boller, Chief Engineer.

FLOOR BEAMS, PEDESTALS AND PIERS.

Figures 2 to 13, inclusive, illustrate some characteristic details of the construction of the superstructure shown in the general elevation on page 295. The other connections, though carefully designed for the given conditions, do not present features differing essentially from the usual first-class work of this kind in American railroad practice.

Figure 2 is a half elevation (at Z Z, Fig. 4), of an end floor beam in the 310-foot span. Figure 4 is an elevation at Y Y, Fig. 2, and Fig. 3 is a section at X X, Figs. 3 and 4, with the end post and lower chord removed to show the connection of floor beam and pedestal.

Figure 5 is a half elevation of an intermediate floor beam of the 164-foot 6-inch span, and shows the riveted connection to the floor beam of the cap B, which receives the lower chord pin.

Figure 6 is a half elevation of an intermediate floor beam of the 310-foot span, and shows its rigid connection to the vertical post by the angles H and D. F F are lateral rods attached to pin G. Figure 7 is a half elevation of the end floor beam of the draw span. Figure 8 is an elevation from T T, Fig. 7, and shows, in addition, the end post, lower chord and pedestal. Figure 8*a* is a section at Q Q, Fig. 8; C is a box inclosing and supporting the lifting gear, which is operated by the 3½-inch shaft I, driven through bevel gearing from the pivot pier. On shaft I is fixed the 13-toothed pinion J that meshes into the 36-toothed gear wheel K. The latter is keyed to the 9-inch cylindrical pillar L, which has a ½-inch thread, giving it vertical motion in its bearings M M. N is a foot piece attached to L, and making contact with the bedplate O when the draw is closed.

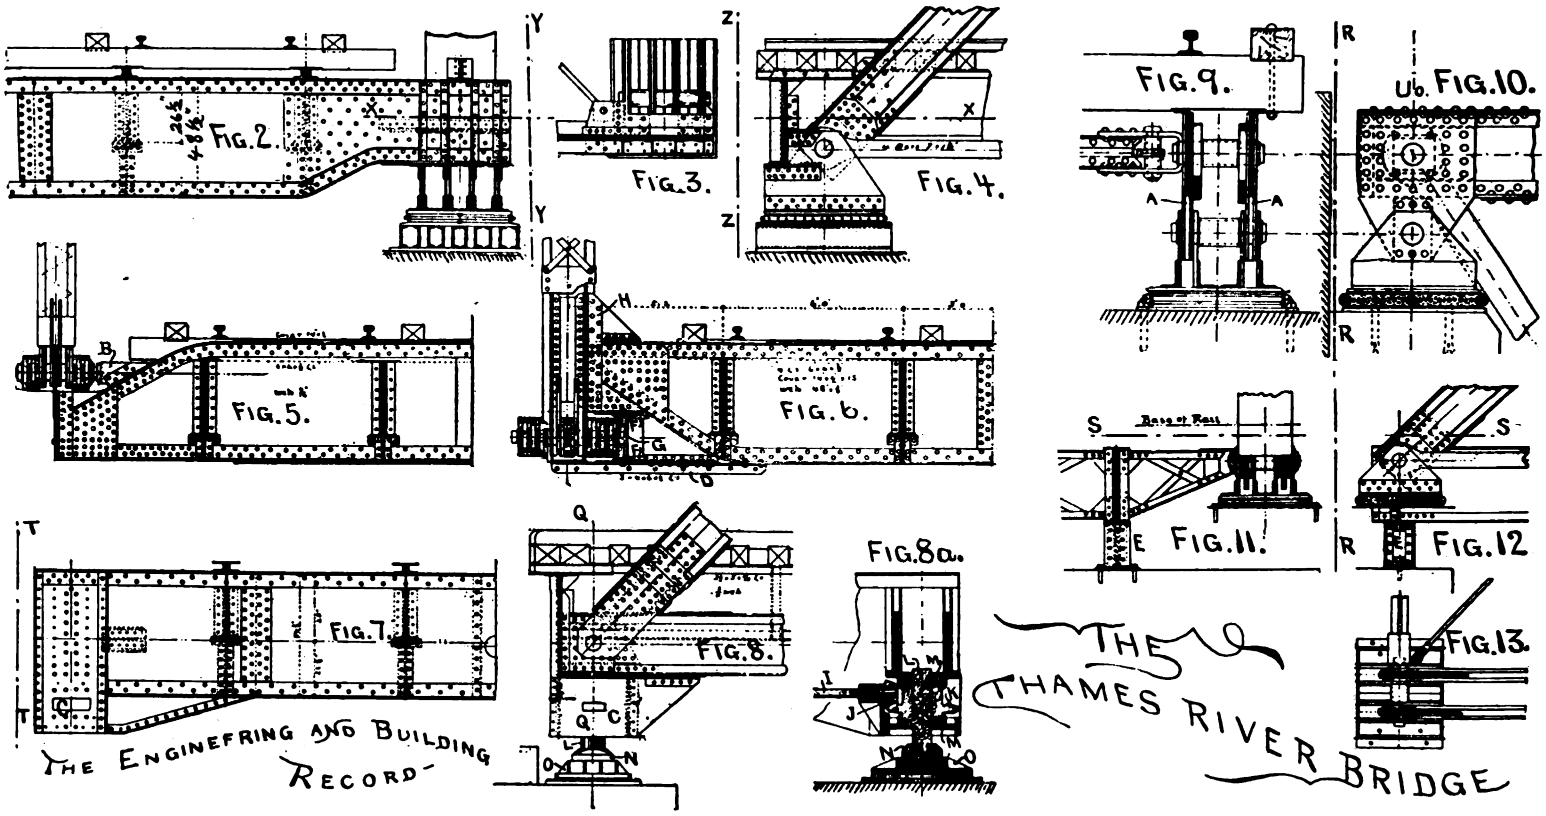


Figure 10 shows the rocker bearing on links A A, at the expansion ends of the end spans. Figure 9 is an elevation and section parallel to R R, Fig. 10. Figure 11 shows the support on the box pedestal E, of a track stringer at the west approach. Figure 12 is an elevation at R R, Fig. 11, and Fig. 13 is a section at S S, Figs. 11 and 12. Figure 14 shows the foundation of pier V. Figures 15, 16 and 17, show the construction of pier II. The other piers are similar to this.

A scheme, now said to be under consideration by the Caledonian Railway Company, Scotland, to accelerate their through traffic from England to the North of Scotland, involves either the bridging or tunneling of the Forth. There would thus seem to be promise of a rival to the present famed Forth bridge.

---

*An historical and fully descriptive account of location, conditions, comparison and construction of foundations, design of superstructure, turning gear, signal apparatus and final tests, was published October 11.

PHILADELPHIA BRIDGE SPECIFICATIONS.

In the specifications just issued by the Department of Public Works, of Philadelphia, Pa., for wrought-iron approaches to the proposed bridge over the Schuylkill River, at Walnut Street, an unusual feature is noticed in the description of the longitudinal and transverse plate girders, for which the dimensions of all the principal angles and plates are given separately so as substantially to constitute a mill bill of material.

Besides the usual requirements for first-class girder work the specifications contain the following clauses:

"Bituminous concrete shall be laid upon the floor of roadway extending from curb to curb, 38 feet 2 inches in width. It shall be 1¼ inches in depth on the flat plates at curbs, and 1 inch in depth over crowns of the three middle rows of buckled plates of roadway.

"The bituminous concrete shall be composed of finely-grounded Val de Travers asphalt mastic, 50 parts, containing in itself as imported, not less than 15 per cent. by weight of bitumen; refined Trinidad asphalt, 10 parts; washed pea gravel and fine broken stone not exceeding ½ inch in largest dimensions, free of dust, 40 parts. The materials shall be heated at the bridge in the usual French kettles. The mastic and refined asphalt shall be heated together to a temperature of about 300° Fahr. The fine pebbles shall then be added and the whole mass thoroughly stirred and incorporated, forming an asphalt mortar. With this asphalt mortar the bituminous concrete will be formed, composed of two parts of asphaltic mortar and generally three parts of fine broken stone of a size suitable for the purpose and never exceeding 1½ inches in their largest dimensions. The proportion of stone may be decreased if desired at the time of construction, and it shall be heated to about 300° Fahr. before being mixed with the mortar. The concrete thus made shall be poured upon the wrought-iron deck of roadway, and by means of smoothing irons and wooden rubbers brought to a true grade.

"The surfaces upon which this composition is placed shall be free of moisture, and the face of cast-iron curb shall be painted with pure asphalt. All joints shall be absolutely water-tight."

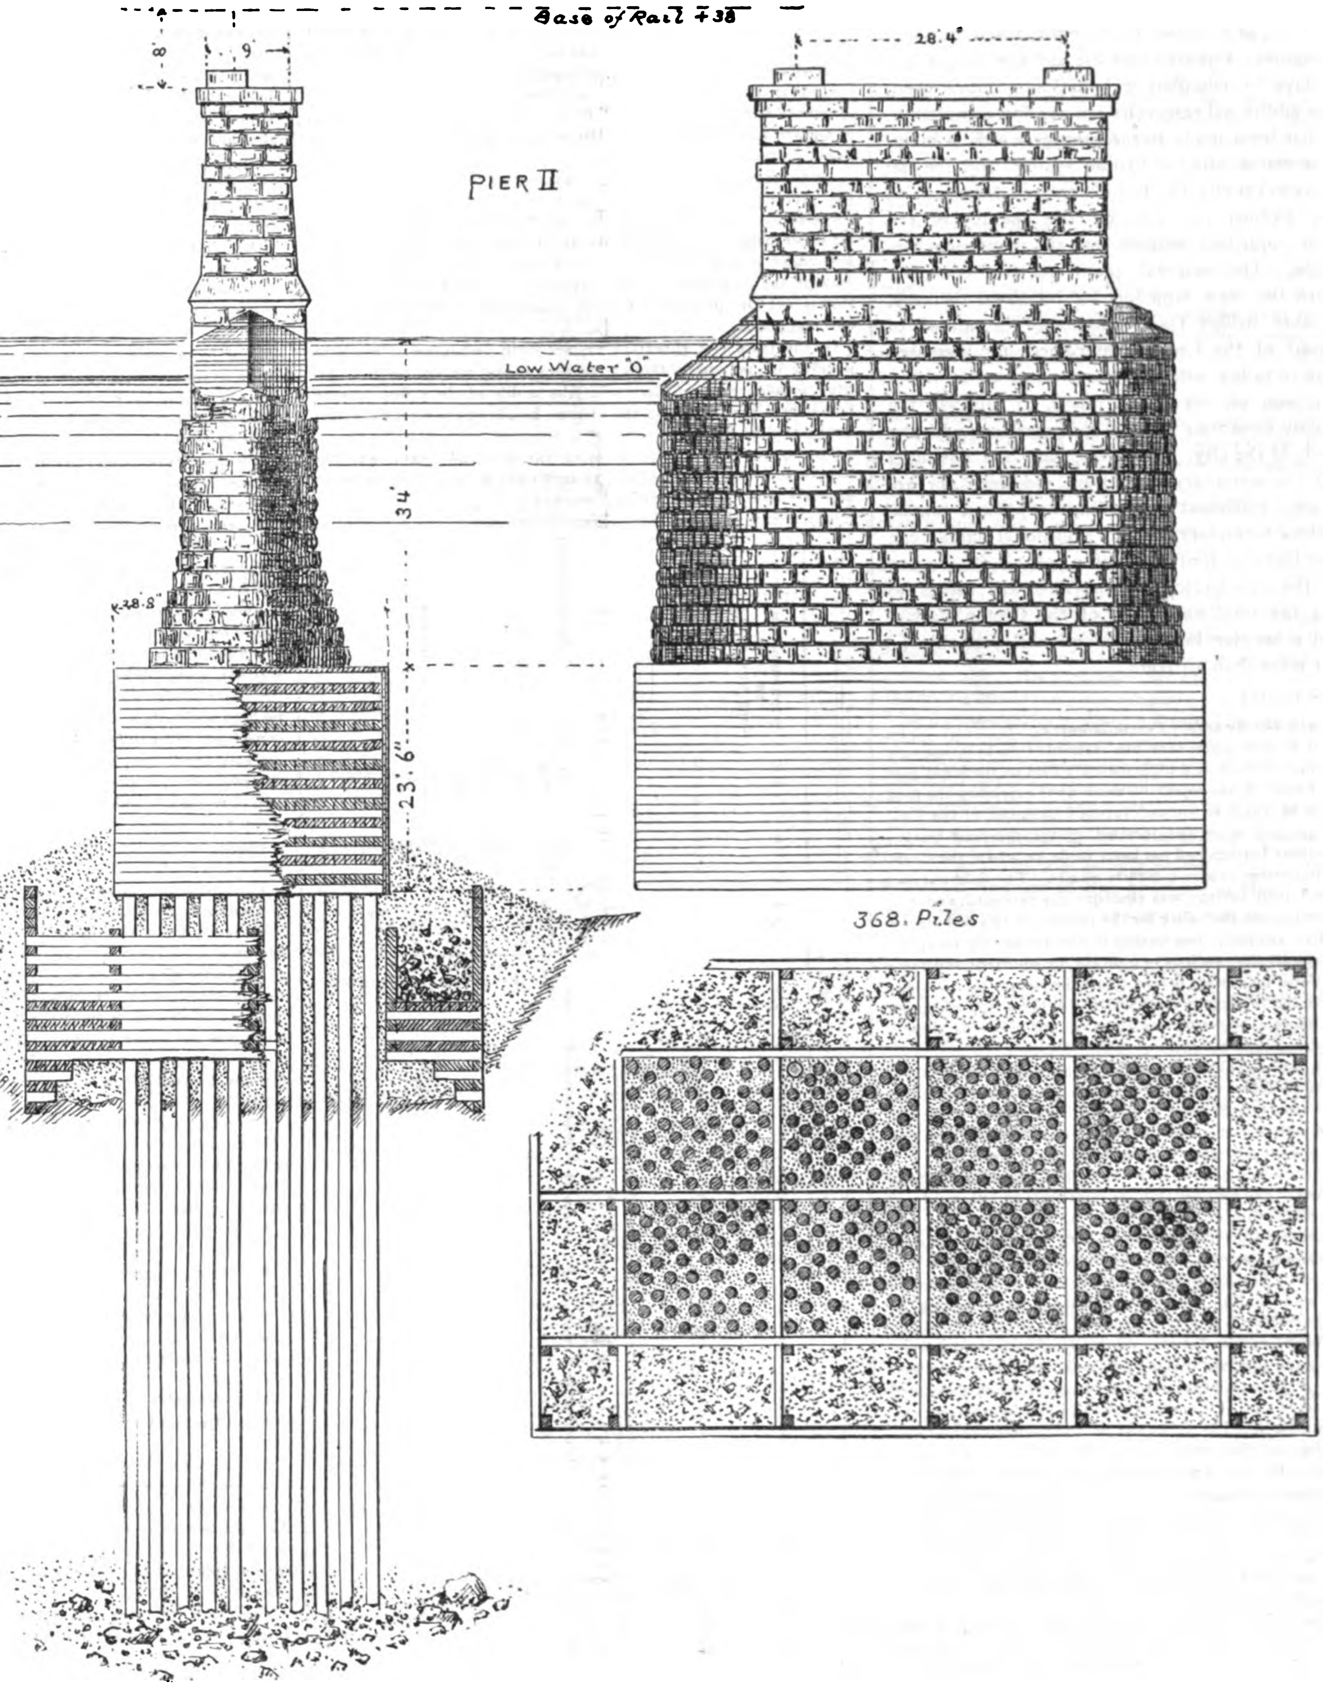
According to the recently issued report of S. M. Gray, City Engineer, of Providence, R. I., the average daily consumption of water in that city, for the year 1889, was 5,786,961 gallons. This includes waste and leakage, and the additional supply of about 18 miles of distributing pipes located in adjoining towns, and of the greater part of the State Institutions at Cranston.

ZINC IN CONTACT WITH BRICKWORK.

In an item which has appeared at intervals during the last two years, and is credited to a German paper, it is stated that in building the Berlin city market halls a portion of the zincwork which rested upon brick walls rapidly decayed, and as a preventive, the introduction of roofing-felt between the brickwork and the zinc is suggested.

Referring to this, Messrs. A. & C. Harston of London, England, write as follows to the *Building News*:

"There may be something peculiar in German bricks or mortar; but we have had a large experience in zincwork in England, and have never found any premature decay in the turns-up or flashings against brickwork. As to the introduction of roofing-felt under zinc, your readers should be cautioned against the recommendation. We were called in to report on the defects of a large flat, not laid under our superintendence, under the zinc of which roofing-felt had been laid over the boarding of the flat. No other cause of the decay of the zinc could be found than that the acids of the tar-felt had acted chemically on the zinc, and pitted it all over with small holes. No doubt hair-felt, not tar roofing-felt, would have been harmless, if unnecessary; but roofing-felt is always worked up with coarse tar, and should for this purpose be avoided."



Figs. 15, 16 and 17.
From the recently published report of Alfred P. Boller, Chief Engineer.

THE NEW CROTON DAM.

THE subjoined report of Chief Engineer A. Fteley, submitted to the Aqueduct Commissioners, of New York City, on October 8, has so important a bearing on the question of New York's water supply, which has always been fully discussed in our columns, that we give it practically in full and reproduce some of the most striking of the drawings that accompany it.

The report is a summary of the results and conclusions of Mr. Fteley's special investigations of the last two years, and will be submitted by the Commissioners to the "public hearing" on October 27. It describes the original conditions and proposed system, the present conditions and the future necessities and possibilties. So long ago as 1880, in a season of drought, Isaac Newton, then chief engineer, reported that the storage supply was within 15 days of complete exhaustion. Since then, though some additional reservoirs are nearing completion, no increase has been made to the storage which is maintained in connection with the Croton system, and the delivery of water to the city has been increased from 115 to 150 million gallons per day by the opening of the New Croton Aqueduct without at all increasing the actual supply. The original plan was to construct *simultaneously* the New Aqueduct for increased delivery, and the Quaker Bridge Dam to impound the rainfall of the largest part of the Croton water-shed, for increased storage; then to follow with additional dams across tributary streams, and on the upper levels, to increase the storage capacity from time to time. in accordance with the growing needs of the city. However, only the aqueduct and some of the secondary dams were completed, or are under contract. Sufficient supply for the present can be secured by these secondary dams. Additional supply can be secured in three or four years at a cost of $2,500.000 by building the new Croton Dam. This will utilize 30 per cent. of the total water-shed of the Croton Valley, which would otherwise be wasted, and will probably be adequate for more than 20 years.

The report reads:

To the Honorable the Aqueduct Commissioners:

GENTLEMEN: In December, 1888, you instructed me to investigate anew the question of building a high masonry dam on the lower part of the Croton River. I was especially desirous of extending the field of investigation in regard to the underground formation of the Croton Valley, above and below the location of the proposed Quaker Bridge Dam, where borings had not been made or where they were not sufficient in number to give complete results. The field covered by the diamond drill borings was consequently extended, and test holes were driven along the valley for the purpose of establishing, on a continuons line. the depth and quality of the underlying rock, and wherever the results were such as to indicate an apparent favorable location, additional holes were driven across the stream for the purpose of ascertaining the approximate sections of the solid rock under the surface. Especial attention was given to such places as present promising superficial indications.

The general results of these investigations show that the rock underlying the valley forms an excessive trough, the bottom of which lies from 60 to 100 feet or more below the bed of the river; this trough is filled with drift material, generally composed of hard pan and boulders, and, at places, of peculiarly hardened sand.

The present river bed is mostly in the drift, sometimes directly over the thalweg of the rock depression; sometimes on either side, so that the greatest depth of the rock is found either in the river bed itself or at a distance from it. At places the rock crops out in the river bed itself; but in such cases it has been invariably found that it dips sharply therefrom. The lowest point examined on the river, about a mile from its estuary, Fig. 3, may be mentioned as presenting on the surface remarkable favorable indications, the stream being there inclosed in a narrow canyon between two walls of rock; as, however, the appearance of the rock on the left bank left some doubt about its soundness and continuity, borings were made, which developed important layers of very soft material underlying the superincumbent rock, at such a depth as to put out of the questton the advisability of building at that point a very high dam; especially as the proximity of the Hudson River, and the great depth of the water, might have presented too great risks of loss through percolation.

Rock was also found in the river bed, at points marked: "Intermediate," "Cornell's," "Purdy's Brook," "Wire Mill Bridge," "Bailey's Brook," and "Location 2," Figs. 1, 2 and 3, and on other sheets, but at all these points, as previously stated, the rock was found to dip under the other side of the valley.

The investigation just referred to was made with the aid of two, and subsequently of three diamond drills; also by means of numerous test pits and trenches wherever the rock was supposed to be sufficiently near the surface to be reached with that simpler and less costly method, 176 holes were bored, covering a total aggregate of length of 14,005 feet.

After comparing the various sections which have been investigated, diagrams of which accompany this report, I do not think it necessary to call your further attention to more than three sites, below the present Croton Dam—viz.:

First.—The site of the proposed Quaker Bridge Dam.

Second.—The site designated as "Cornell's."

Third.—The site designated as "Location 2," C and D, a little less than a mile below the Croton Dam. (See Fig. 3 and other sheets.)

Quaker Bridge site is well known to you.

The Cornell site, Fig. 3, is located one and one-quarter miles abov Quaker Bridge, and presents several favorable features.

At that point, the width of the valley at high-water line is 1,736 feet; the greatest depth at which the rock is found is 23, nearly 40 feet higher than at Quaker Bridge; the earth excavation necessary at that point is larger, but it would take place at such a distance from the river as not to be in the way of the greatest freshets. A portion of the surface on the south side is favorably situated for the construction of a partial earth embankment and the overflow could conveniently take place over a spill-way of great length, built in an almost parallel direction with the contours of the valley on the northern bank of the river, the surplus water thus flowing in a channel with a gradual slope from its highest point to the river bed.

The water shed at that point is only one and one-half square miles less than it is above Quaker Bridge. The storage will be practically the same; the dam would not be as handsome a structure, but it would cost less, and its total height would be 40 feet less at the deepest point; the conditions as to the imperviousness of the side hills would, to all appearances, be superior.

On the whole, if it were found advisable to build the originally proposed high dam at Quaker Bridge, or in its vicinity, the merits of Cornell's site should be carefully considered before deciding on a final location.

In these two cases it is thought that, owing to the great height of the proposed structure, an all masonry section should be mostly used; earth banks with a masonry core have been used successfully for lesser heights, and, if built to the height necessary in the cases now under consideration, might be found equally reliable; but, in view of the importance of the interests involved, it is believed that this is not the place for trying an experiment of such a character and magnitude.

On the third site (Location 2), an earth embankment would be justified by practice, although an all masonry section could, if desired, be adopted. At that point the width of the valley between flow lines is 1,000 feet, and the extreme height of the crest above the river would be 100 feet.

The accompanying table, showing the principal features of the structure and the estimated cost in each case, is given for the better understanding of the following remarks:

Location.		Extreme Height* above River Bed.	Extreme Depth below River Bed.	Extreme Total Height.*	Length of Dam between Flow Lines	Capacity in Gallons.	Estimated Cost.			Probable Time of Construction.	Water Shed above Dam.
							Dam Proper.	Railroads, Roads, Bridges and Clearing.	Muscoot Dam, as previously estimated.		
Quaker Bridge..........		Feet 180	Feet. 91	Feet. 271	Feet. 1,402	34,000,000,000	$4,087 000	$1,075,000	$300,000	6 years.	377.8 square miles.
Cornell's...		159	70	229	1,736	30,000,000,000	3,650,000 (Approx'te)	1,075,000	300,000	5 years.	376.3 square miles.
No. 2.	Masonry.	105.5	100.5	206	995	16,000,000,000	2,450,000	910,000	300,000	4 years.	355.4 square miles.
	Earth and Masonry as Recommended.	105.5	100.5	206	995	16,000,000,000	1,750,000	910,000	300,000	3 to 4 years.	355.4 square miles.

* Top of Dam assumed at elevation 206 feet.

Before going further in the comparison of the four structures just referred to, permit me to call your attention a moment to the general conditions of the water-shed of Croton River, which is now being further utilized for the water supply of New York, and to the facts which render the construction of a dam on the main stream a matter of necessity.

The water-shed can be divided into two parts: one containing all the partial sheds corresponding to the various reservoirs built, in process of construction, or proposed, the other covering all the territory between these reservoirs and Croton Dam. This territory will vary in area according to the number of smaller reservoirs that may be built on the affluents, but it must necessarily be large; on the map appended to the report of the Chief Engineer of the Department of Public Works of February 21, 1883, it is represented as being 115 square miles, or about one-third of the whole water-shed. This area can be diminished by the location of additional dams on the lateral streams, but it would remain to large to be overlooked. The only possible means of collecting the drainage from the lower territory is a new reservoir of large capacity on the main stream, the present Croton Lake not being of sufficient capacity to perform that function.

Not to build such a reservoir at a low point on the main stream would be equivalent to the exclusion from the source of supply of a large portion of the water-shed.

This fact is forcibly illustrated by the records of the storage during the dry season. For instance, in the middle of September of the present year, when the present storage basins, owing to the dry weather, had been drawn from to the extent of a number of feet below the flow line, a copious rain produced a heavy overflow of Croton Dam, amounting to over 600 million gallons per day, while the upper reservoirs, covering comparatively limited territory, had shown but a small increase. It is true that subsequent rains filled all the reservoirs after a few days, but had dry weather prevailed instead, the waste of water over Croton Dam would have been keenly felt.

An additional and very weighty argument in regard to the location of such a reservoir is that, although the present Croton Dam has rendered good service for half a century, it must be conceded that it is not built in such a manner as a structure should be, on which depends the very life of New York, and it is necessary that it be replaced by a more substantial one. It may be said also that, inasmuch as the important parts of the New Aqueduct system are now built in view of the construction of a high dam on the lower part of the river, the rest of the work should be made to conform to the existing features.

For these reasons, and in view of the fact that the capacities of the Croton water-shed must be as fully developed as circumstances will warrant, it is hoped that the necessity of a large reservoir built below the present Croton Dam is sufficiently demonstrated, but the site where the dam forming such a reservoir should be built has not been as ye decided upon by your Commission.

When the work now in your charge was begun, the plan adopted included the location, in connection with the New Aqueduct, of a single reservoir a short distance above Quaker Bridge, the intention being to build from time to time, as the wants of the city should warrant, a number of large although smaller reservoirs higher up on the water-shed. The plan was then consistent and it was indorsed by high authorities; the reservoir being single had to be of a large capacity in order to furnish the required storage. One of the most essential conditions, however, for the carrying out in a full and consistent manner, the plan of the designers, was to begin the construction of the dam simultaneously with that of the New Aqueduct, or a short time afterwards, inasmuch as it would have required most probably not less than six years to complete an undertaking of such magnitude.

The situation is now radically different. Owing to the delay in coming to a decision as to the location of the Quaker Bridge Dam, it became evident that no additional storage could be procured at the time of the completion of the New Aqueduct, except by means of reservoirs which could be completed within a shorter time. The speedy procurement of such additional storage having become a question of absolute necessity, a dam on the east branch of Croton River was put under contract, then on Bog Brook, subsequently on Titicus River, and recently on the west branch near Carmel; in addition the Amawalk Dam is being built by the Department of Public works.

The dams just enumerated are designed to intercept the drainage of the upper parts of the water-shed, but the necessity of one being built on the lower part of the main stream remains, as has been explained, for the storage of the rain water which falls in the lower part of the basin.

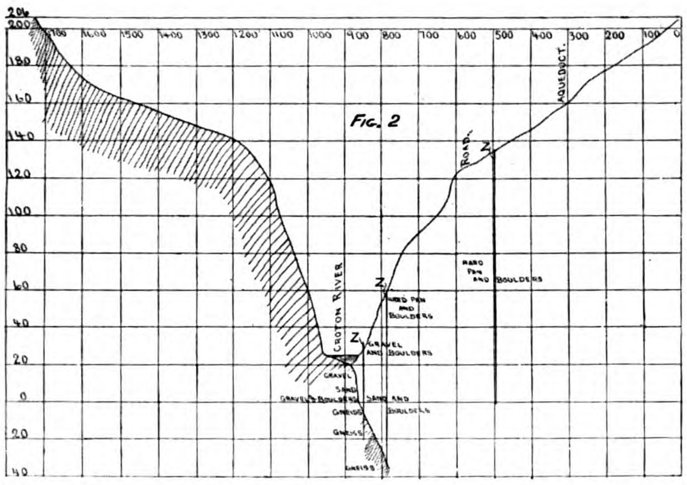
At this time, however, it may be properly questioned whether, at least for a long time to come, as large a storage as was to be provided by the Quaker Bridge Reservoir is consistently needed, and whether it would not be more advisable to build, at a smaller cost, a structure of less magnitude, which would furnish ample storage capacity for the next 20 years, and possibly for the whole extent to which the supply from the Croton water-shed should be properly developed.

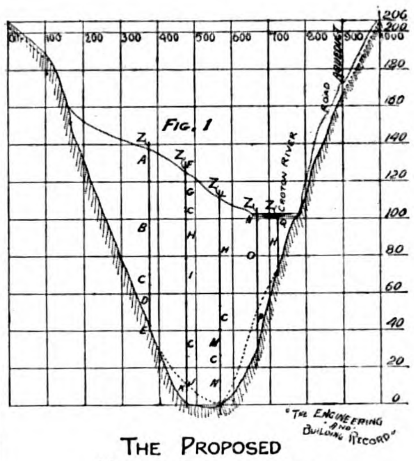
A site favorable for a structure of the kind just described has been found at the point already mentioned, nearly one mile below Croton Dam.

At that point the Croton Valley, if the water were raised to the same height as was proposed for the Quaker Bridge Dam, would form a reservoir of a capacity of 16 billion gallons. The following data in connection with it may be of interest. Above this site the water-shed has an area of 355 $\frac{37}{100}$ square miles; 22$\frac{4}{10}$ square miles less than at Quaker Bridge Dam, and 1$\frac{8}{10}$ square miles more than at the present Croton Dam.

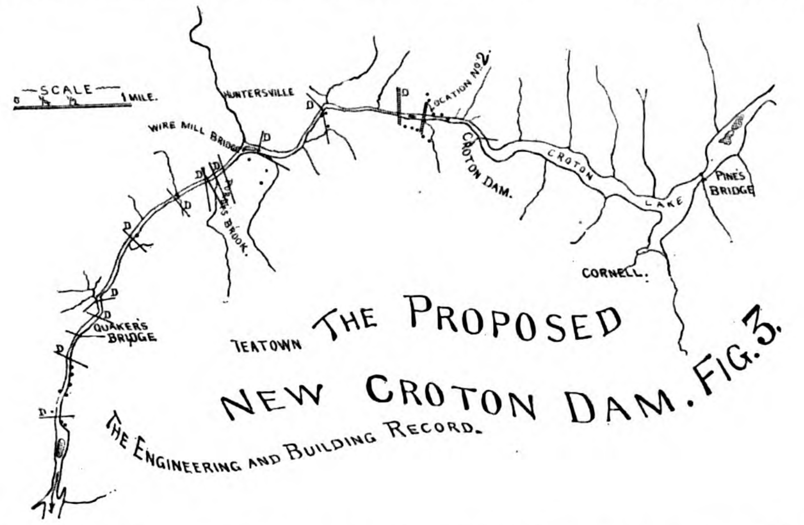
Records of the gaugings taken for many years show that the amount of water collected in the stream at Croton Dam in the year extending from February, 1880, to February, 1881 if entirely retained for the use of the city, would have furnished a daily average of a little less than 250 million gallons In order to ascertain the probable results of the system of storage, including the reservoir just mentioned at site No. 2, I caused computations to be made of the records of flow, day by day, during the extreme dry year 1880-81, and applied them to the probable management of the storage on the supposition that two such extreme dry years would follow one another, and that at the beginning of the first the reservoirs were, in one case, full, and in another case half full (see Fig. 4), the amount of water collected in and drawn from such reservoir being taken in proportion to its individual drainage area to the total area of the water-shed. The diagrams indicate the fact that, after taking into account the loss by evaporation, there would be left at the end of two years, just before the spring freshets, an amount of storage equivalent in the first case to 14,000 million gallons, in the second case to 8,000 million gallons, Owing to the well-known irregularity of the rainfall over various parts of the water-shed and in successive years, it is obvious that the actual distribution of the flow for two subsequent dry years would vary from the results just presented, but they are sufficient to show that, in the instance given, covering two successive very dry years, a daily supply of 250 million gallons would have been maintained, with a surplus equivalent to an additional daily quantity of about 40 million in one case and of 20 million gallons in the other.

In the uncertain condition of the census returns as regards the increase of the population of New York during the last decade, owing, also, to the exceptional condition of the water consumption of the city, which for years has been so inadequate that, since the opening of the New Aqueduct, it has shown in two months, I am informed, an increase of 35 million gallons per day (in all 150 million gallons), it is difficult to estimate how long the system of water-works just described would be sufficient; but unless waste is allowed to increase beyond ordinary limits it would be ample, if we include all the proposed reservoirs in the upper part of the water-shed, for the next twenty years.



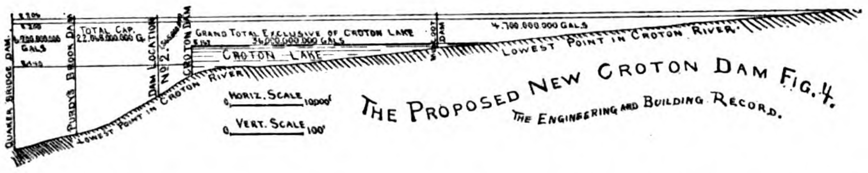


THE PROPOSED NEW CROTON DAM



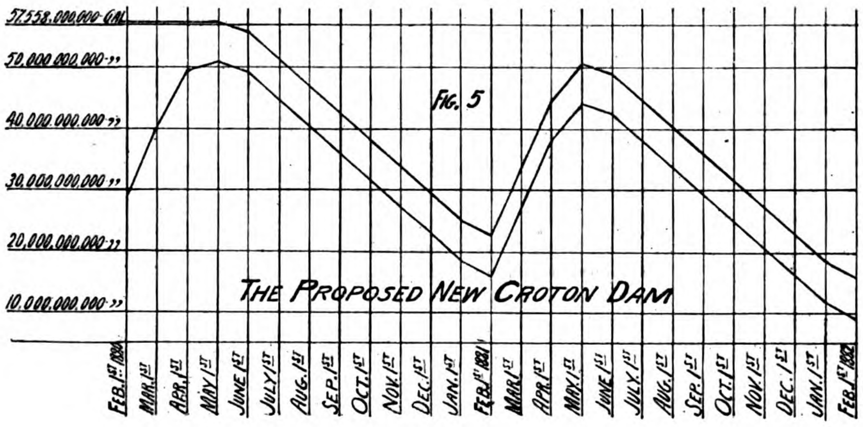
THE PROPOSED NEW CROTON DAM. FIG. 3.

THE ENGINEERING AND BUILDING RECORD.



THE PROPOSED NEW CROTON DAM FIG. 4.

THE ENGINEERING AND BUILDING RECORD.



THE PROPOSED NEW CROTON DAM

If this statement be admitted, it will be seen by reference to the table given above that the accumulated interest of the sum which could be saved at the present time by building the dam at Site No. 2 would be more than equal to the cost of its construction, and that, at the end of the time named, if it were found advisable to procure an increase of the water supply by the erection of a higher dam further down in the valley, it could be properly done without increased cost to the city, with the additional and obvious advantage of having two dams instead of one for the control of the immense body of water to be impounded.

By that time, also, the experience of a number of years in handling the constantly growing quantities procured from the water-shed would furnish increased and invaluable knowledge in regard to its capacities; in regard to the effect of the exceptionally large volume of the storage on the quality of the water; in regard to the subsequent advisability of accumulating the storage to add to the natural flow of dry years, and, ultimately, when the time would come for further action, in regard to an intelligent selection between an increase of the storage system of Croton water and the possible procurement of an additional and larger supply from the Housatonic River. At this point it may not be out of place to recall that your attention has already been directed to the advisability of preparing the way for future works by procuring a topographical survey of the 200 square miles of the Housatonic water-shed, which lie in the State of New York. It is to be regretted that doubts were expressed as to your jurisdiction in the premises, and that owing to them this useful work remains undone.

In conclusion: After reviewing the whole subject, and although fully recognizing the merits of the Quaker Bridge and Cornell's sites for the construction of a high dam, circumstances are now so different, owing to the construction of a number of reservoirs in the water-shed, from what they were when the new supply system was originally planned, that it is not thought advisable to recommend at present the construction of either.

A dam built at site No. 2, one mile below Croton Dam, is considered amply sufficient; its immediate construction is recommended and the accompanying plans, designed from the knowledge acquired of the topographical formation of that part of the Croton Valley, show its principal features. The dam could be entirely built of masonry; it is thought, however, that with the great size given to the spillway and the unusual height of the top of the structure above the latter, an earth embankment, as shown, would be sufficient and safe for a large part of the length, and could be built in less time, at less cost.

If compared with the higher dam formerly proposed its inferiority consists in draining a water-shed about six per cent. less extensive in area. Its superiority consists in the following: It can be built in much less time, three to four years instead of six; the land to be taken is of less area to the extent of 1,600 acres: the necessity of building a high and costly bridge at the Wire Mill Road and over the present Croton Dam, is avoided; the construction of new roads and bridges between this site and Quaker Bridge becomes almost wholly unnecessary, the whole cost is much less and, the dam being of much less height above the bed of the river, all the risks of accident, loss by leakage, delays, etc., which are proportional to the height and length of the dam are proportionally diminished.

The proposed dam, which, if built, would properly be named the New Croton Dam, is shown on the accompanying plan.

The spillway extends along the side hill a distance of 1,000 feet with a stepped channel to convey flood water to the river below. The height of its crest is at elevation 197 above tide, with three feet left for movable stop-planks. The top of the embankment is at elevation 220, and supports a road with a bridge over the spillway to connect with the highway on the other bank. The structure contains two sets of gates; one for the direct connection of the impounded water with the old aqueduct, the other of a very large capacity, for the emptying of the reservoir in case of need. The total contents of this reservoir would be 16,000,000,000 gallons. The same reasons which determined the construction of the Muscoot Dam, in connection with that of the Quaker Bridge Dam, for the purpose of keeping at an even and high level the water in the upper parts of the basin, exist in this case.

The location just described for a new Croton dam is not now mentioned for the first time. I am informed that at the time of the original construction of the present works the site had been seriously considered for the erection of the dam. Moreover, Chief Engineer Isaac Newton, of the Department of Public Works, in his report of February 21, 1883, refers to the fact that a dam could be built immediately below the present one, but that owing to the width of the valley, and to the absence of rock, he has not found it advisable to recommend it. His objection to the site is removed by the result of the underground survey now submitted to you.

With the construction of the new Croton Dam, the total storage available, including the present reservoirs and those under construction, would be over 50,000,000,000 gallons—*i. e.*, more than 200 days supply at the rate of 250,000,000 gallons per day, and would be larger after the construction of Reservoirs O and N, and others.

In the accompanying illustrations, Fig. 1 shows the profile at the point known as dam location No. 2, and recommended for the site of the new Croton Dam. The horizontal and vertical distances are marked on the margins, and the heavy line, with hatched edge, shows the position of the solid rock bed here continuous. Z Z, etc., are the sounding lines and the reference letter indicate the nature of the strata—viz.:

A, loam and boulders; B and H, hard pan and boulders; C, sand and boulders; D, hard sand and boulders; E, seam; F, loam and clay; G and O, hard pan and boulders; I, N and Q, gravel and boulders; J, rock, sand and gravel; K, soft gueiss rock; L, soil; M, hard sand; P, sand and soft rock.

Figure 2 is a similar diagram of the profile at one of the other proposed sites, which have been sounded by diamond drill borings. Here the rock exists, as indicated, on the left side and disappears altogether in the apparently similar right side.

Figure 3 is a diagram of part of the Croton Valley water-shed, and shows the Quaker Bridge and Croton Dam sites. Location No. 2, and at several places marked D D, etc., the positions suggested and examined for a dam site. The small black dots indicate the position of some of the diamond drill soundings.

Figure 4 shows the profiles and relative positions and capacities of the reservoirs formed by the different proposed dams.

Figure 5 shows, graphically, the storage capacities in two successive dry years of the proposed reservoirs, assuming them to have been respectively full and half full at first, and receiving the recorded rainfall, and drained by the estimated demand.

KEY WEST, FLA., is probably the first city which has thus far contracted for grading and paving the entire length and breadth of her streets. According to local advices, it is to be no piecemeal job, but one that, when completed, will thoroughly alter the face and appearance of the place, changing it from a third-rate country village as to streets and sidewalks, to a modern city.

NEW YORK is shortly to [illegible] ed wharf for the receipt of Southern frui [illegible] There is said to be only one other st [illegible] his country—at Boston, Mass.

PNEUMATIC HOISTING.

ACCORDING to a paper read at the New York meeting of the American Institute of Mining Engineers, a few weeks ago, by H. A. Wheeler, the system of pneumatic hoisting, as installed at the Hottingeur shaft of the Epinac colliery, Saone-et-Loire, France, was designed by M. Zulma Blanchet, who was the managing director of a large company operating several mines and a local coal-railroad at Epinac, in Central France. The first suggestion for thus using air was made in 1852 by M. Gruner, the Director of the School of Mines of St. Etienne, and a model constructed on this principle was exhibited by M. Cave, at the first Paris Exposition; but the credit of first putting the system into practical operation is due to M. Blanchet.

The vertical Hottingeur shaft, started in 1863, had reached a depth of 2,133 feet in 1871, and was to be sunk to a depth of at least 3,300 feet; but, unfortunately for the company and the entire mining world, no workable coal has thus far been met with, so that, instead of developing a large mine to raise over 700 tons a day, it still remains (1889) a prospect, while the plans of M. Blanchet were not satisfactorily completed on account of the great expense of installation and the discouraging nature of the explorations. So, although a thorough test of the system was not made, according to M. Blanchet's more advanced ideas, yet sufficient experience was gained to furnish evidence as to the practical desirability of this novel system of extraction.

M. Blanchet's plan was to have one or two continuous air-tight sheet-iron cylinders or large tubes extending from the bottom to the top of the shaft. Within the cylinder moved a piston, to which was hung a cage with as many decks as desired, nine decks being used at Epinac, while suitable air-tight doors open out at each level for allowing the decking of the cars. It was operated by exhausting the air from above the piston, and as the lower side was open to the atmosphere, the piston was raised by the difference in pressure of the atmosphere and the vacuum produced by the air-pump. For lowering, it was merely necessary to allow the air to re-enter above the piston by a throttle-valve, while the speed could also be regulated by throttling the escape of the expelled air from below the piston. It is obvious, that, neglecting the friction of the piston, any lifting capacity desired can be obtained for a given vacuum by merely increasing the diameter of the tube, while the speed of hoisting will depend on the capacity (size and speed) of the exhausting-engine to maintain this vacuum.

Besides its legitimate function as a hoisting device, M. Blanchet was enthusiastic about the additional services it would perform in cooling and ventilating the mine, through the introduction at each trip of the volume of air represented by the depth of the shaft and the diameter of the cylinder. With a tube 3,000 feet long, 63 inches diameter, there would be delivered into the workings during a round trip of 12 minutes a volume of 5,425 cubic feet of air per minute, which positive acquisition would be no insignificant item; and the deeper the shaft the greater would be the volume of air expelled at each trip. In coal practice, however, this amount of air would be entirely too small to be entitled to much consideration.

That the pneumatic system will be more exempt from accident than the cable system Mr. Wheeler considers hardly probable, in view of the want of a reliable, continuous system of recording the positions of the cage in the tube. Overwinding or carelessness on the part of the landers or engineers, quite a frequent cause of accidents at present, seems likely to become even more dangerous in the pneumatic system. The trouble arising from the distortion of the shaft with consequent jamming of the cage in swelling or heaving ground, would be exaggerated in the pneumatic system, with its train 52 feet long; for while the tube stands free by itself away from the shaft-lining, the displaced timbers supporting it would so distort and throw it out of line as to readily cause the jamming or sticking of the train in the tube.

The expense of the pneumatic system proper was given to Mr. Wheeler by M. Naugerode, the present superintendent, as follows: Tube and connections, $70,000; erection, including winch-engine, etc., $74,000; exhausting engine (or vacuum pump), $42,000; total, $186,000.

These figures show that the erection of the tube cost more than the tube itself, and that the tube (with its connections) cost about $35 per running foot. As there are 775 pounds metal per linear foot, this shows a factory cost of the tube of about 4½ cents per pound. It is probably safe to say that such a tube erected complete in this country would cost over $100 per linear foot. This does not include the vacuum engine, boilers, housing and the primary cost of first sinking the shaft. So that a pneumatic plant, complete, would call for at least double the capital of a rope-hoisting plant of equivalent grade, and when finished, aside from probably much greater operating expenses (fuel and repairs), would not have a fifth of the capacity of the cable system, as reckoned on the actual figures of the Epinac plant.

COST OF WATER IN DIFFERENT CITIES.

W. B. BULL, Superintendent of the Quincy, Ill., water-works, in a letter to a local paper, furnishes the following table, taken from the Erie, Pa., water-works report. It gives the cost of water to the average householder in 25 cities, compiled from official reports:

Allegheny City	$24.50
Boston	37.25
Buffalo	25.50
Chicago	21.75
Columbus, O	32.80
Dayton, O	45.30
Detroit	28.25
Erie, Pa	21.75
East Saginaw, Mich	26.50
Fall River, Mass	31.00
Grand Rapids, Mich	33.00
Indianapolis	32.00
Lawrence, Mass	25.80
Milwaukee	22.00
Minneapolis	26.00
Newark, N J	26.25
New York City	32.75
Omaha, Neb	30.00
Philadelphia	28.75
Pittsburg	23.50
Sandusky, O	25 50
St. Paul	24.80
Syracuse	31.75
Toledo	28.50
Utica, N. Y.	31.50

It appears from the above statement that $28.66 per annum is the average price paid for water by the householder circumstanced as above in the United States, if the above 25 cities afford a fair basis from which to construct an average.

STRENGTH OF MILL FLOORS.

THE following tables have been prepared and issued in circular form by C. J. H. Woodbury, one of the vice-presidents of the Boston Manufacturers' Mutual Fire Insurance Company, for the purpose of furnishing a convenient means for determining safe loads on floors; also for use in designing floors that are to be adapted to specific purposes. It is not assumed that these tables will do away with the services of an engineer in general construction, but rather that they may be convenient in many cases where the master mechanic of the works may make plans or supervise changes in construction. The utmost care should be observed to select the figure giving the greatest possible amount and concentration of load as the one which may be put upon any beam or set of floor beams, and in no case should beams be subjected to greater loads than those specified, unless a lower factor of safety is warranted under the advice of a competent engineer.

Mr. Woodbury states that whenever and wherever solid beams or heavy timbers are made use of in the construction of a factory or warehouse, they should not be painted, varnished, oiled, filled or incased in impervious concrete, air-proof plastering or metal for at least three years, lest fermentation should destroy them by what is called "dry rot." It is, on the whole, safer to make floor beams in two parts, with a small open space between, so that proper ventilation may be secured, even if the outside should be inadvertently painted or filled.

The tables apply to distributed loads, but, according to Mr. Woodury, the first can be used in respect to floors which may carry concentrated loads by using half the figure given in the table, since a beam will bear twice as much load when evenly distributed over its length as it would if the load was concentrated in the center of the span. The weight of the floor should be deducted from the figure given in the table, in order to ascertain the net load which may be placed upon any floor. The weight of spruce may be taken at 36 pounds per cubic foot, and that of Southern pine at 48 pounds per cubic foot.

Table I. was computed upon a working modulus of rupture of Southern pine at 2,160 pounds, using a factor of safety of six. In can also be applied to ascertaining the strength of spruce beams if the figures given in the table are multiplied by $\frac{78}{100}$; or in designing a floor to be sustained by spruce beams, multiply the required load by $1\frac{28}{100}$, and use the dimensions as given by the table.

The tables are computed for beams one inch in width, because the strength of beams increases directly as the width, when the beams are broad enough not to cripple; that is to say, a beam 14 inches in width will sustain twice the load of a beam 7 inches in width.

Example.—Required the safe load per square foot of floor which may be safely sustained by a floor on Southern pine 10 by 14-inch beams, 8 feet on centers, and 20 feet span. In Table I. a 1 by 14-inch beam, 20 feet span, will sustain 118 pounds per foot of span, and for a beam 10 inches wide the load would be 1,180 pounds per foot of span, or 147½ pounds per square foot of floor for Southern pine beams. From this should be deducted the weight of the floor, which would amount to 17½ pounds per square foot, leaving 130 pounds per square foot as a safe load to be carried upon such a floor. If the beams are of spruce, the result of 147½ pounds would be multiplied by $\frac{78}{100}$, reducing the load to 115 pounds. The weight of the floor in this instance amounting to 16 pounds, would leave the safe net load as 99 pounds per square foot for spruce beams.

TABLE I.—*Safe Distributed Loads Upon Southern Pine Beams One Inch in Width.*

(If the load is concentrated at the center of the span, the beams wil sustain half the amount as given in the table.)

Span, Feet.	DEPTH OF BEAM IN INCHES.

Table II., Mr. Woodbury explains, applies to the design of floors whose strength must be in excess of that necessary to sustain the weight, in order to meet the conditions of delicate or rapidly moving machinery, to the end that the vibration or distortion of the floor may be reduced to the least practicable limit. The usual method of prescribing the limit which may be permitted in the deflection of beams on which machinery is to be operated has been to select a direct ratio to the span, customarily one four-hundredth, and to prescribe a proportionate deflection for all spans. Mr. Woodbury holds that a better rule would be to base the deflection which may be permitted upon the amount of curvature or distortion which the yielding of the floor may bring into effect upon the machinery. In the table the limit is that of load which would cause a bending of the beams to a curve of which the average radius would be 1,250 feet.

This table is based upon a modulus of elasticity obtained from observations upon the deflection of loaded storehouse floors, and is taken at 2,000 pounds for Southern pine. The same table can be applied to spruce, whose modulus of elasticity is taken as 1,200,000 pounds if sixteenths of the load for Southern pine is taken as the proper load for spruce; or, in the matter of designing, that the load should be increased one and two thirds times, and the dimension of timbers for this increased load is found for the table used for spruce.

It can also be applied to beams and floor timbers which are supported at each end and in the middle, remembering that the deflection of a beam supported in that manner is only four-tenths that of a beam of equal span which rests at each end; that is to say, the floor planks are two and one-half times as stiff, cut two bays in length, as they would be if cut only one bay in length. When a floor plank two bays in length is evenly loaded, three-sixteenths of the load on the plank is sustained by the beam at each end of the plank, and ten-sixteenths by the beam under the middle of the plank; so that for a completed floor three-eighths of the load would be sustained by the beams under the joints of the plank, and five-eighths of the load by the beams under the middle of the plank; this is the reason of the importance of breaking joints in a floor plank every three feet in order that each beam shall receive an identical load. If it were not so, three-eighths of the whole load upon the floor would be sustained by every other beam, and five-eighths of the load by the corresponding alternate beams.

The method of applying Table II. is similar to that already given for Table I. Repeating the former example for the load on a mill floor on southern pine beams 10x14 inches and 20 feet span laid 8 feet on centers; in Table II. a 1x14 inch beam should receive 61 pounds per foot of span, and for a beam 10 inches wide this would be 610 pounds per foot of span, or 75 pounds per square foot of floor for Southern pine beams. From this should be deducted the weight of the floor, which would amount to 17½ pounds per square foot, leaving 57 pounds per square foot as the advisable load to be carried on such a floor.

If the beams are of spruce the result of 75 pounds should be multiplied by sixteenths, reducing the load to 45 pounds. The weight of the floor in this instance amounting to 16 pounds would leave the net load as 29 pounds for spruce beams.

There are many instances where similar beams safely sustain loads far in excess of the above, but it is repeated that Table II. applies only to what is considered advisable to resist the amount of bending and vibration to which light machinery, running at high speed, should be subjected.

If the beams were two spans in length, they could, under these conditions, support two and a half times as much load with an equal amount of deflection, unless such load should exceed the limit of safe load as found by Table I., as would be the case under the conditions of this problem.

THE SEWAGE OF LONDON, PARIS, AND BERLIN.

IN a recent lecture at London, on the above subject, Dr. C. R. Drysdale declared that the only method of treating the sewage of large cities was that now employed at Berlin, Paris and Croydon. In his opinion, London presented a very bad example to other cities by the manner in which it dealt with the sewage. Paris had at present 1,500 acres of land in the Plain of Gennevilliers, cultivated by small proprietors, who made use of about 20,000,000 tons per annum to irrigate their farms. Some 3,000 acres had also been acquired at Achères, which it was proposed to cultivate in the same manner; and the authorities were contemplating still another sewage farm. The effluents were perfectly pure. The land at Gennevilliers often produced from $300 to $800 per acre. At Berlin the acreage in sewage farms amounted to 19,000 acres. To these the sewage was pumped from 12 pumping stations, through pipes 40 inches in diameter, and most of the farms had been under cultivation during the past 15 years About 2,000 hands were employed, and no case of typhoid occurred during the whole of last year. A sum of $16,055,000 had been borrowed for successfully dealing with the sewage of 1,500,000 of inhabitants. Sir R. Robinson estimated that the present sewage experiments for London, with over 5,000,000 inhabitants, would cost 10,000,000 of money. The effluents at Berlin were perfectly pure and drinkable, as at Paris. The Paris Commission recently sent to Berlin had reported the system a perfect success.

AUTOMATIC REGISTER OF MOVEMENTS OF THE FORTH BRIDGE.

THE Forth Bridge has been for some time entirely completed, the works have been dismantled, and the engineers' staff and the workmen have had to seek new fields of operations, some of the engineers having gone to Mexico, the United States, Greece, and India. The finishing touch, it is interesting to note, is the only thing in the way of ornament on the bridge, all else being indispensable parts of the structure. This embellishment, according to *Engineering*, consists of two brass plates placed on the south cantilever pier, in commemoration of the opening of the bridge by the Prince of Wales on March 4, 1890. The names of the directors, engineers, and contractors are also given. Sir John Fowler has had fitted at the end of the south main span, at which point the contraction and expansion joint is placed, an indicator to record the number of trains passing and the daily contraction or expansion of the bridge. The apparatus consists of a brass rod, with a pencil, attached to the end of the girder, and a clock with another brass rod fixed in its axle. Round the rod in the axle of the clock is wound a strip of paper about 4 inches wide with a weight attached to the end. The point of the pencil rests on this paper, which is, of course, constantly on the move as the clock winds down. The result is that as the cantilever contracts the pencil attached to it is pulled away; when it expands, the pencil is pushed forward, and a curve of contraction and expansion is thus produced by the movement of the paper and pencil combined. The same principle is applied to register the behaviour of the bridge while a train is passing. When the train enters on the one end of the cantilever it pulls the far off end down, and when it does so it also pulls the pencil, and thus a mark at right angles to the curve of contraction and expansion is made. When it passes to the other half of the cantilever, it pushes it forward and again a mark at right angles to the curve is made on the other side. Each mark indicates a train, and thus the simple apparatus serves three purposes. Recently there was a second sale of the plant in the works, and now the bridge alone stands without anything to indicate that it has only been just constructed. Of the 4,500 men who once were employed on the bridge only 80 remain, and of these 80 only 36 are likely to be permanently employed on the bridge. Their chief work will be to keep the bridge thoroughly painted both outside and inside. It is not generally known probably that the painting of the inside of the bridge is not yet finished. When the work has been once done only the junction of the members will require constant touching up. The paint on the other parts will last for two or three years. In order to overtake the work with as great convenience as possible, permanent steel staging has been devised. There will be a stage for each member. Each stage has been so constructed that it can be taken down and put up again in a form that will suit the place it is desired to get at. The management are at present troubled a good deal with requests for passes to inspect the bridge; but as walking over the bridge, owing to the narrowness of the sidewalk, is attended with considerable danger, very few are granted. The speed of the trains in crossing the bridge is not now limited, except in the case of freight trains, and with them it must not exceed 25 miles an hour. As there are only about 2 feet 6 inches between the pedestrian on the bridge and the flying train, it is seen that the precaution is wise. The average traffic on the bridge amounts to about 140 trains daily.

ONE of the matters to be discussed at the annual meeting of the American Institute of Architects, to commence at Washington, D. C., on the 22d inst., is the establishment of testing stations for building material. It is thought that the work of such stations will promote safe building, as it would give the architectural profession an opportunity to have new materials and methods of construction tested by trained officials.

Correspondence.

Communications giving information or opinions on matters of general interest to the engineer, the architect, the contractor, or the municipal officer, will be welcomed in this column. Fairness will suggest that when communications are sent simultaneously to this and other journals we should be informed of it at the time. Anonymous letters will not be noticed.

LARGE SIZE VITRIFIED PIPE FOR SEWERS.

CITY ENGINEER'S OFFICE,
OMAHA, NEB., October 8, 1890.

To the Editor of THE ENGINEERING AND BUILDING RECORD:

Sir: I have been much interested in the discussions in your paper lately regarding the material for small-sized sewers. The difference in practice seems to be great; so great, in fact, that I sometimes wonder if I am all wrong in what I am doing. In Omaha we have about 65 miles of pipe sewers, all of which have been laid since 1881. My practice has been to use vitrified pipe up to and including sewers of 24 inches in diameter. Our specifications call for extra strong pipe, 2 inches thick for a diameter of 24 inches. We have had no instance of failure of pipe, except where the trouble was with the foundation. Pipe sewers must have a good foundation and a firm, even bearing. This is of the greatest importance.

I fully agree with Mr. Hering in what he says regarding the method of laying pipe, and the relative value of pipe and brick sewers. In brick sewers, my practice is to use two rings of brick for all sewers over 24 inches in diameter up to 72 inches. From there on, I increase to three rings. Bricks are all supposed to be first-class sewer bricks, laid in Portland cement, tested to stand a tensile strain of 200 pounds per square inch after remaining one hour in air and 24 in water. These precautions would probably surprise Colonel Waring, who seems to think that as soon as the quantity of material is increased inspection and watchfulness are decreased in the same proportion. How absurd the proposition! If this be true, it is fair to infer that in a building a 16-inch wall would be weaker than one of 8 inches, because the latter would have better material.

My experience has been that contractors are governed almost entirely by the moral influence with which a department surrounds a work. They are as quick as school boys to ascertain their chances of slighting their work, and as quick to recognize thorough, vigilant inspection. It seems to me that your correspondent from Illinois is greatly at fault in recommending sewers of 5 feet in diameter, and in some cases "very much larger," to be built of a single ring, and I must confess that I cannot see one single reason why a single-ring sewer should be a "better job" than a sewer of the same size constructed of two rings.

In your last issue, Mr. Samuel Gray expresses my views almost exactly.

GEO. W. TILLSON,
City Engineer.

Questions and Answers.

All questions relating to building construction, paving, sewerage, water supply, or kindred subjects, will be welcomed in this column provided they relate to matters of general interest and are not such as should properly be referred to a consulting engineer. Answers will be carefully prepared and a proof of both question and answer mailed to the inquirer as early as proper consideration will permit. They will be published for the benefit of other readers as soon as convenient. The full name and address should be given, not necessarily for publication, but as a guarantee of good faith, and to facilitate further correspondence in case the question is not sufficiently explicit.

Inquiries of the Editor, in order to secure prompt attention, should *not be written on the same piece of paper as a communication* to the *Publishing Department*. Letters renewing subscriptions are sent to a clerk in the publishing office, and matter for the Editor, if in the same enclosure, is likely to be overlooked unless it is on a separate piece of paper, so that it may be promptly sent to the Editor.

LAYING WATER MAINS AROUND CURVES.

"WATER-WORKS," Newark, N. J., writes: "Will you kindly state in your next issue the maximum deflection, in inches, per length of 12 feet, allowable for laying water mains around curves, for sizes of 12-inch, 10-inch, 8-inch, 6-inch and 4-inch? How is the calculation made of the effect of pressure to open the joints, and how should they be secured against such contingency while being laid?"

[No hard-and-fast rule can be given to meet the above inquiry. The practice is not to deflect to such an extent as to prevent proper calking of the joint in its narrowest part. The depth and thickness of the joint, the character of the soil and the water pressure, are all factors to be considered.

Each joint should be well backed up with concrete between the outer edge of the pipe and the undisturbed bank of the trench. A curve of 100 feet radius can generally be laid with straight pipe. On curves of shorter radii ⅛ bends must occasionally be introduced.]

THE first electric underground wires are now being laid at Cincinnati.

DOMESTIC PLUMBING HEATING LIGHTING & VENTILATION ENGINEERING

ELECTRIC MOTORS.

(Continued from page 301.)

THE BARRIETT MOTOR.

The Barriett Motor, made by the New York Electrical Manufacturing Company, 10 West Twenty-third Street, New York, is constructed of few parts and in a manner calculated to give a low center of gravity and consequent freedom from vibration when running.

The cores of the magnets are made of Norway charcoal iron. The armature is a modification of the Siemens drum form. All the motors are equipped with automatic oilers of special design, insuring cleanliness and good lubrication.

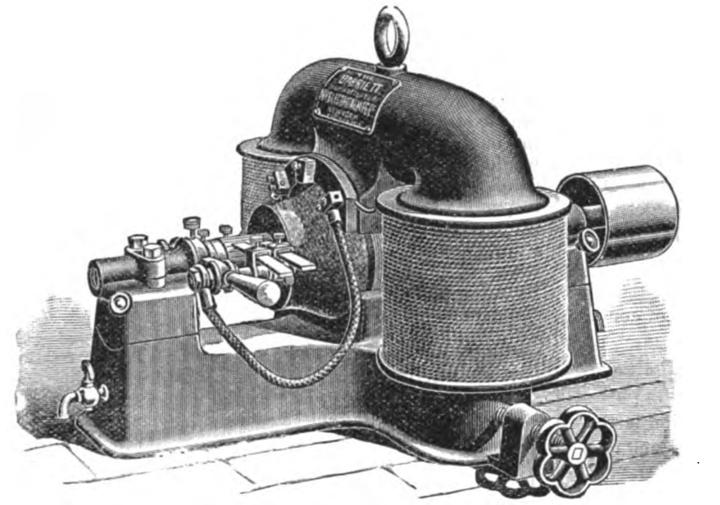

Fig. 8.- THE BARRIETT MOTOR.

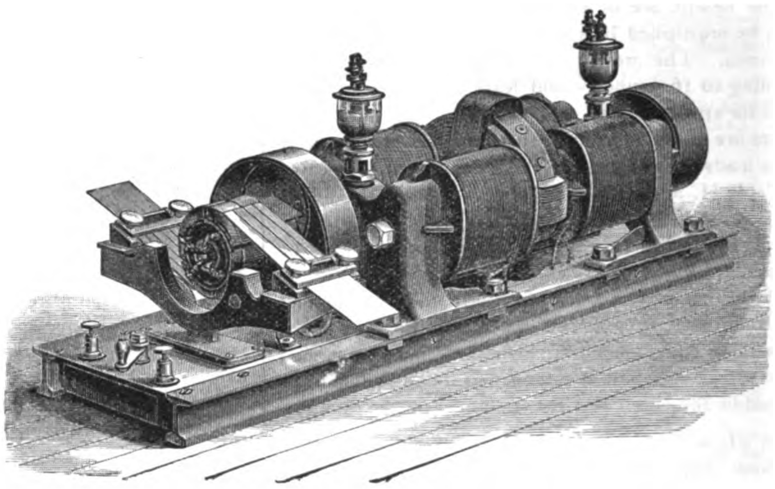

Fig. 9 —THE BRUSH MOTOR.

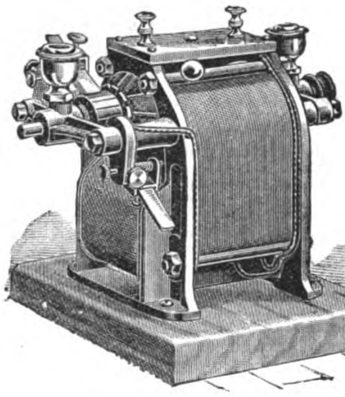

Fig. 10.—TYPE A.

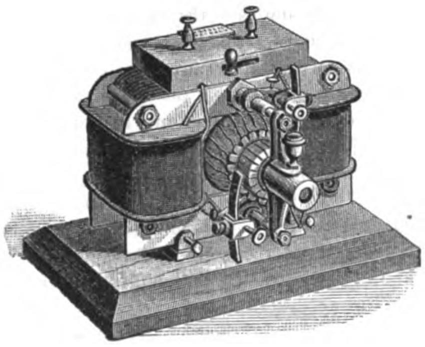

Fig. 11.—TYPE B.

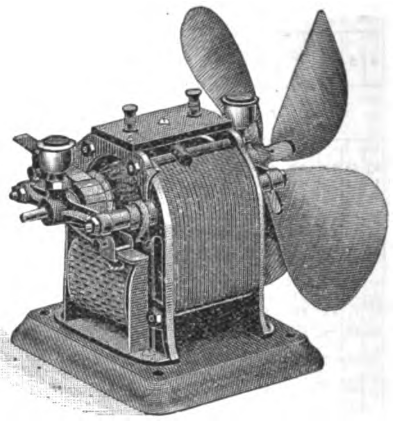

Fig. 12.—FAN OUTFIT.

THE A. B. C. MOTOR, MADE BY THE A. B. C. MOTOR CO., NEW YORK.

The motors are made in capacities ranging from $\frac{1}{2}$ to 25 horse-power. In addition, a special fan outfit of $\frac{1}{16}$ horse-power is put on the market. Figure 8 will help to give an idea of the general character of the design.

THE BRUSH MOTOR.

The Brush Motor is made by the Brush Electric Company, of Cleveland, O.

Figure 9 shows one of 1 horse-power. Several thousand Brush motors are now in use, doing various kinds of work. They are strong and compact, and claimed to be highly efficient. Their governing arrangements, also, are claimed to be excellent. According to the makers, not only are the similar parts of all the motors of a given size absolutely interchangeable, but the wearing parts and many other details of all the sizes commonly used are also interchangeable. This is a noteworthy advantage, and is of much importance to any one using a large number of the motors. All the mechanical details have been carefully considered and worked out.

Noteworthy applications of Brush motors are to be found in some of the large mines at Virginia City, in Nevada. Water power is there used to generate the current, and the motors furnish power for hoisting, working stamp mills, and other kinds of mining machinery.

The Brush motors range in capacity from $\frac{3}{4}$ horse-power up to 100 horse power.

THE A. B. C. MOTOR.

The A. B. C. motor is made by the A. B. C. Motor Company, 44 Gold Street, New York. Two types are shown in the accompanying engravings, Fig. 10 representing type A, which embraces the sizes $\frac{1}{12}$, $\frac{1}{8}$ and $\frac{1}{6}$ horse-power, and Fig. 11 representing type B, which continues the sizes by quarters up to 1 horse-power.

The principal feature of these machines is found in the laminated field magnet, which is claimed to be composed of the softest and purest iron obtainable. The advantages of this are universally recognized by electricians. The other features are stated to be a very slow speed, rendering countershafting frequently altogether unnecessary; the maintenance of a constant speed under all loads without sparking or noise; simplicity and durability of construction.

The $\frac{1}{12}$ horse-power machine is intended for use with either a primary or storage battery. Its principal use is for operating a ventilating fan or running a sewing machine, although it is not by any means confined to these purposes, but is available for any demands that may be made upon it up to $\frac{1}{16}$ horse-power. All the other sizes are constant potential machines (that is, intended for incandescent circuits), and are wound for any voltage up to 220. They are in use in machine shops, printing houses, and for operating pumps, blowers and fans. Figure 9 shows a $\frac{1}{8}$ horse-power motor with fan attached.

A third type of motor made by the company, and known as type C, embraces all powers from one horse-power upwards, and can be wound for any voltage up to 500.

(To be continued.)

A SIMPLE GAS RADIATOR.

A Brooklyn architect, Mr. G. L. Morse, has hanging over his office table a very simple and inexpensive radiator, of his own design, consisting of a cylinder of black sheet iron, 8 inches in diameter and 14 inches high, open at the bottom, but closed at the top. This is suspended from the chandelier directly over its drop light with an ordinary 6 foot fish-tail burner, which stands on the table, and Mr. Morse says that this arrangement will keep his private office, which is quite a good-sized room, some five degrees warmer than the adjoining rooms, even with the doors open—a difference of temperature which, at this time of year, will often just make the difference between comfort and chilliness.

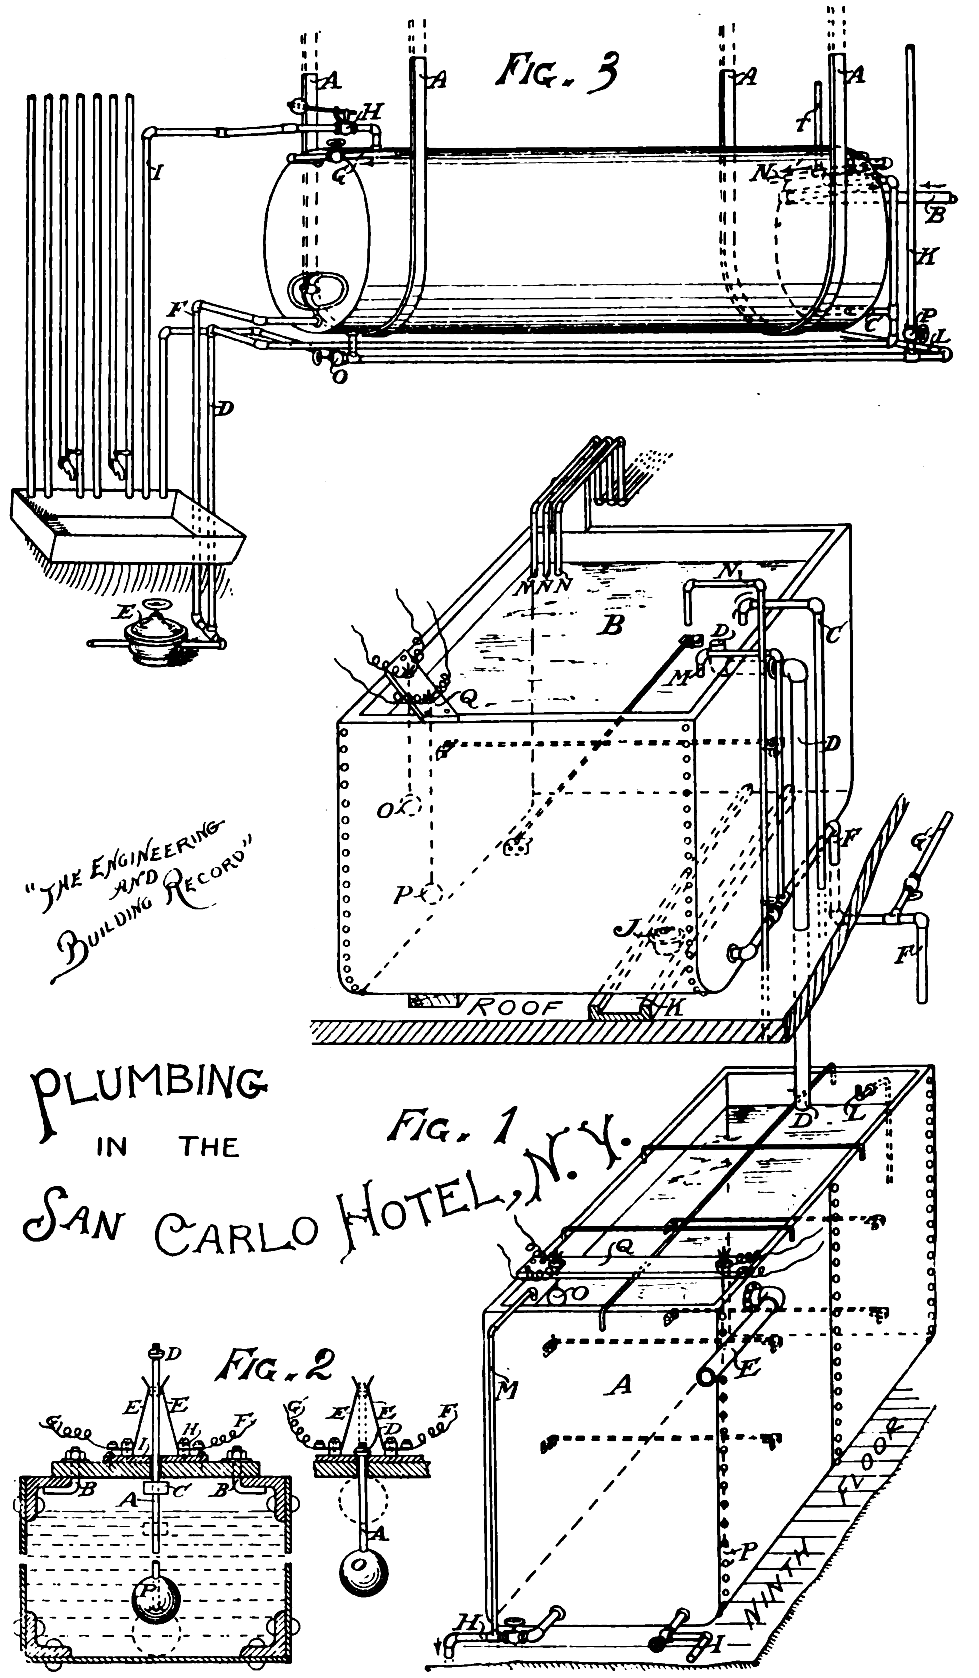
This device, even if made to order, would cost but little, and could be readily improvised with a short length of stove-pipe by cleaning it of soot and closing the top, which, if appearance was not considered, could be most readily done by flattening the pipe. This closing the upper end is necessary, to avoid the current of cold air that would be drawn in along with the heated gases, if there were a draft through, and which would lower the temperature of the radiator. An old tin pail hung bottom up, and blackened outside to promote radiation, would also answer the purpose very well. The top of the flame should be about level with the bottom of the radiator. If the radiator is too low the flame will smoke and deposit soot on the inside of the radiator, impairing its efficiency and being liable to soil anything under it.

SOME PLUMBING DETAILS IN THE SAN CARLO HOTEL, NEW YORK.

When this hotel was finished, about a year ago, it was intended to take all the house water supply from main tank A, Fig. 1, on the ninth floor, but as it was afterwards decided to place servants' rooms, etc., on the ninth floor, the supplementary tank B was built on the roof above and arranged to furnish cold water to ninth floor fixtures, and to supply the boiler for hot water throughout the house. All water is, therefore, pumped through the 1½ riser C, and, after filling tank B, the surplus overflows through the 3-inch pipe D into the tank A, and may overflow from that tank to the roof through the 4-inch pipe E. F is a 1½-inch pipe to the basement boiler with branch G supplying cold water to the ninth floor only; H is a 1½-inch cold-water supply to all fixtures below the ninth floor; I is a 1-inch pipe through which tank A can be emptied to the roof gutter; J is a common bath tub valve by which tank B can be emptied, the water escaping through trough K to the roof gutter; L is a tell-tale to the drip sink in engine room; M M are ¾-inch vent pipes to admit atmospheric pressure to rising lines F and H, and facilitate their emptying after the upper valves are closed; N, N, etc., are relief pipes; O O and P P are copper floats that operate electric alarms in the pump room, the former for high and the latter for low water.

The details of the floats are shown in Fig. 2, where P and O are the copper balls fixed to ¼-inch brass rods A, and supported from shelf boards Q Q that are fastened to the tanks by bolts B B.

For the low water alarm, rod A is about as long as the tank is deep, and has a fixed collar C that prevents it from rising above the position shown by full lines where the buoyancy of the float usually maintains it; E E are copper springs, *not* in contact with the rod A. When the tank is nearly empty, the float falls to the position shown by dotted lines, and the button D, engaging the copper springs E E, completes through them the circuit between wires F and G., and rings the alarm gong in pump room. H H are insulating washers, and I is a metal base plate. The high water alarm float O operates similarly. Ordinarily it is in the position shown by full lines. When the tank is full it rises to the position shown by dotted lines, and the circuit is made as before described.



PLUMBING IN THE SAN CARLO HOTEL, N.Y.

FIG. 3

FIG. 1

FIG. 2

Figure 3 shows the basement boiler for furnishing hot water throughout the house. It is suspended from the iron floor by iron straps A A.

Exhaust steam is received through the 2½-inch pipe B, passes through an inside coil, and comes out at C, discharging through pipe D and trap E; F is a 1-inch drip pipe from the coil; G is a ¼ inch pipe through which live steam can be forced into the water; H is an ordinary safety valve with waste pipe I.

Cold water from roof tank B, Fig. 1, is supplied through 1½-inch pipe K; L is the ¼-inch hot water return circulation pipe. The valve P is usually open and O closed, but if thev are reversed the boiler can be emptied through 1-inch pipe M: N is the 1¼-inch hot supply which has valves in the pump room controlling its branches to different parts of the house; T is a thermometer. The boiler and steam pipes are jacketed with asbestos, which is not shown in the illustration, to avoid confusion.

The plumbing was executed by Mead & Rossman, of New York.

ACCORDING to Col. F. R. Hain, General Manager of the New York elevated railroads, the management is looking forward to the adoption of a storage battery system of electric traction for the different lines.

Novelties.

Devices are described under this head purely and strictly as news; because believed to be new and calculated to interest readers.

In no case is pay accepted, directly or indirectly, for publishing a novelty notice.

As the subjects are selected for their supposed novelty and interest merely, it will, of course be understood that the selection does not imply indorsement.

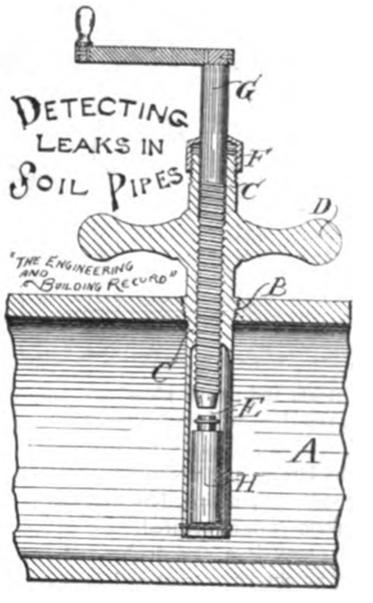
NEW FORM OF PIPE HANGER.

ERNEST V. CLEMENTS has assigned to the De La Vergne Refrigerating Machine Company, of New York, a patent for a new form of pipe hanger. The hanger consists of a lag bolt to be screwed into the ceiling beams, the bottom of the bolt being split, or formed into two horizontally projecting arms. The tops of these arms are rounded, and over them fits a stirrup or loop for supporting the pipe. The advantage of this construction is that the stirrup will swing and provide for the changes in length of the pipe through expansion and contraction.

DETECTING LEAKS IN SOIL PIPES.

THE device illustrated herewith is intended to facilitate the application of the well-known peppermint or other similar tests for discovering leaks in soil pipes.

Through the soil pipe A at a point near the bottom a hole B, preferably conical, is tapped and receives the screw plug C, which has an open cage or receptacle E at one end and a handle D at the other. The stem of the plug C is bored and tapped to receive the spindle G which works through a stuffing box F.



DETECTING LEAKS IN SOIL PIPES

In making the test a fragile bottle H, containing some pungent volatile liquid, is placed in the cage and the plug screwed into the soil pipe; then the spindle G is forced down on the bottle and breaks it, the liquid is released and its fumes penetrate the whole of the pipe and its branches, escaping through any openings. The presence of these is thus clearly indicated. The bottle H should be hermetically sealed, for which purpose a coat of varnish over cork and glass, is recommended.

R. T. Crane, Chicago, Ill., is the patentee, and claims that the method is more efficient than the ordinary peppermint test, because it prevents any possible smearing of the pungent liquid on the bands or outside of the pipe and avoids any chance of the odor's appearance, except through leaks from the interior of the pipe.

STEAM PIPE LAGGING FROM WASTE MATERIAL.

ACCORDING to the *Revue Industrielle*, some of the waste products resulting from the manufacture of paper furnish excellent material for cheap and efficient lagging for steam pipes. The waste products in question are chiefly those coming from the different cleaning and sorting machines, and which are of a fibrous nature. These, when dry, are to be mixed with potter's earth in the proportion of 4 to 1, enough water being afterward added to form a plastic compound. This is spread by hand over the surfaces to be protected, in thin successive layers. When dry, the coating is said to adhere firmly and is not easily broken. Its cost is practically no more than the cost of mixing and applying it.

Notes and Queries

on Domestic Engineering.

Communications relating to the practical details of plumbing, heating, lighting and ventilation will be welcomed in this column. The writer's true name and address must always be given, but an assumed name may be used for publication if preferred.

PUMP RETURN SYSTEM OF STEAM HEATING.

"ARCHITECT," of Providence, R. I., writes: "The accompanying plan is meant to show the arrangement of buildings to be heated by the low-pressure gravity system of steam heating. The pipes are all supposed to have proper pitch for drainage and to be of proper sizes, and the water of condensation will run back to tank, from which it will be pumped into the boiler. If the boiler-house had been below the lowest building, of course there would be no occasion for a pump.

(1) Will both buildings receive their supply of steam with the same facility and of equal dryness? (2) Will it be necessary to have any check or other valves except such as would be necessary to shut off steam, and will any traps be required? (3) Will it be possible, under any circumstances, to produce a vacuum by which the water can be drawn out of the boiler into the tank? (4) The radiators in the building on the low level will be about ten feet below the water line in the boilers."

[The accompanying sketch explains the arrangement of the buildings in question. A is the boiler-house; B, building with radiators below boilers; C, building above grade of boiler-house; T, tank low enough for water to return by gravity from lowest radiators; from this the water is to be pumped back to the boilers; S and S′ are steam and return mains, respectively.

THE ENGINEERING AND BUILDING RECORD

(1) If the steam and return pipes are sufficiently large and properly run there will be no difficulty in having equal dryness and nearly equal pressures at all parts of the apparatus. Absolutely equal pressures cannot be obtained through any system of piping, but differences below the limit of one pound can be secured.

(2) If your tank is a closed one, and your pipes are large enough, no checks or traps will be necessary, and a pump and pump governor will take the water from the tank to the boilers. If the tank is an open one traps will be required on each main return.

(3) If the pump is properly connected with the boilers no vacuum in the tank can draw the water from the boilers, any more than the pressure within the boiler can drive the water out through the check valves and pump.

(4) It matters not how much the radiators are below the water line of boilers in a system such as you propose, so long as they are sufficiently above the tank to allow the water to run to the same by gravitation.]

HEAT REQUIRED FOR DRYING LUMBER.

HENRY G. MORRIS, engineer and machinist, of Philadelphia, Pa., writes: "I find in the *Louisiana Planter and Sugar Manufacturer* a statement in regard to the amount of water which is removed from lumber in kiln drying, as follows:

When it is considered that there are many saw mills cutting as much as 100,000 feet of lumber per day, and drying the same, from 5,000 pounds per 1,000 feet to 2,700 pounds, with no other heat than exhaust steam from the mill engine, the practicability of putting this system to the concentrating of cane juice would seem assured.

What I desire to find is some actual data on the subject of lumber drying, and the amount of heat required to evaporate a definite quantity of water stated, either as units of heat or as quantity of water condensed when steam is used.

Any information that you can elicit upon this subject would be much appreciated."

[We have no actual data on the subject, and shall be pleased to obtain figures from the experience of any of our readers. The amount of steam to be condensed in drying, of course, in every case, will be practically equal to the amount of water removed from the lumber.]

ODORLESS EXCAVATING APPARATUS.

KING & DICKERSON, Peoria, Ill., write: "Will you please tell us, through your columns, what is the best pump or apparatus of any kind for pumping out cesspools or vaults? There is nothing of the kind here. The old way is followed of baling them out by hand. This is both slow and dangerous. We want to buy some kind of an outfit for this work. Can you post us as to the best make—something that you think you can recommend? We want something that will not necessitate sending a man down into the hole. If such an apparatus is not available, we will not risk this kind of work."

[For obvious reasons we can, in no case, undertake to specify which is the best of several pieces of apparatus. In the present instance, the Odorless Excavating Apparatus Company, of Baltimore, Md., are the only makers that we can call to mind of such outfits as our correspondents refer to.]

DIRECT PRESSURE WATER SUPPLY.*

IN the designing and operating of direct pressure systems of water supply for small towns some very interesting conditions frequently arise that are not to be met with elsewhere. In such a system we may meet with the following requirements. A domestic supply of 300 gallons per minute at 50 pounds pressure and a fire supply of 1,200 gallons per minute at 120 pounds pressure; the former to be maintained continuously, the latter not more than six hours per month.

These conditions are usually met by putting in an engine with variable cut-off, or else a compound pump arranged to admit live steam to the low pressure cylinders, thus acting as a non-expansive engine on fire service. This latter is a very satisfactory and economical arrangement for a small town, but it will readily be seen that it will make excessive demands upon the boiler plant at the outbreak of a fire. From the fact that the quantity of water required in case of fire is four times that required for domestic service it is evident that the piston speed will be increased four times, and hence, without considering increase of pressure, four times as much steam will be used.

As on domestic service the fires will be ordinarily banked, the result of an alarm of fire is generally a decided fall of boiler pressure, and hence it is that the live steam connection to the low pressure cylinder is considered so valuable; but this does not completely remedy the difficulty. Consider a pump whose cylinders are 10 inches and 16 inches in diameter. The low pressure cylinder area will then be 2.56 times that of the high pressure. The stroke being the same the volumes will be in the same ratio. A pair of such pumps if duplex will just about meet the requirements laid down above. On domestic service one alone would be run. On fire service both would be run and at double the speed on domestic service. Ordinarily in these pumps on fire service no work is done in the high pressure cylinder, as no separate exhaust is provided for it, so the amount of steam used per stroke on fire service will be 2.56 times that used on domestic service, and as there are four times as many strokes the steam required for fire service will be ten times that required for domestic service, approximately. Of course some diminution of pressure will generally be allowable, but it is safe to say that the fire service will require eight times as much steam as the domestic service. As this demand is one that must be met in a very short time, or the effectiveness of the fire service will be seriously impaired, some special device appears to be necessary in the way of a blower to produce a sudden increase of combustion. While a very high chimney may serve the purpose to some extent, there is at hand a much more effective means of accomplishing the desired result—viz., the exhaust steam. While ordinary fuel consumption varies from 10 to 20 pounds per square foot of grate, a combustion of 120 pounds may be produced by a steam blast. After using steam for heating the feed water and the pump room there is still enough of the exhaust remaining for a good steam blast, for less than one-fifth will be required for the feed water and not more than the same amount for heating any ordinary pump room; the rest would ordinarily go to waste. By utilizing the exhaust steam for a blast, by means of nozzles at the base of the stack, as in a locomotive, a smaller chimney and a smaller boiler plant will be sufficient, thus involving less initial cost; and while it may be argued that a steam blast is of low efficiency and detrimental to the life of the chimney, it seems to us that where it would be used so seldom, and where it would then use only steam that must otherwise be wasted, it could not be anything but a very effective and valuable addition to the plant, and the smaller chimney needed with it could be replaced at small expense when it should become necessary. It is also to be remembered that a good supply of water at the beginning of a fire may be infinitely more valuable than the same supply 20 minutes later, and any device that will assist in insuring such a supply should not be overlooked.

A very interesting point to be considered in direct pressure engines is the economical length of stroke. The stroke should be such that the losses due to condensation in the cylinder shall be reduced as much as possible. This requires that the ratio of volume to surface shall be a maximum. Then, also, the time that the steam occupies the cylinder is another element to be considered. While in a single cylinder engine it is not difficult to determine the best length of stroke to adopt, in a duplex compound pump, where both pistons act along the same piston rod, it becomes quite a complicated problem. Even in this case if the ratio of surface to volume and the time of occupancy of the cylinder by the steam were the only considerations, the solution of the problem would not involve very serious difficulties; but we have to consider the variable clearance, the variable service required of the pumps, and the relative disadvantages of condensation in each of the two cylinders. In an ordinary system of the sort considered, in a small town, as already pointed out, the domestic service will probably require less than one-half the capacity of the pump, and yet the pump must be of the greater capacity for the sake of a few hours' use in a month for fire service, hence a high piston speed cannot be maintained during the greater proportion of the time. So in determining the economical length of stroke we must consider the pump as working at its low piston speed, taking care to introduce no conditions that will be incompatible with the performance of the required fire service. In view of the fact that the sooner the steam can be made to do its work and be exhausted the less will be the condensation, we are inclined to favor short strokes. The condition of minimum surface for maximum volume in a single cylinder makes the length of stroke equal to the diameter of the piston so that we would certainly not make the stroke longer than the diameter of the low-pressure cylinder, and the economical length according with this condition alone would be somewhere intermediate between the diameters of the two cylinders, but condensation in the high-pressure cylinder will be more detrimental than in the low because in the former the water so produced must be carried on through the engine clogging the work in the low-pressure cylinder, while in the latter it is immediately exhausted without further detriment; so we will find it advantageous to favor the high-pressure cylinder as much as possible and make the stroke equal to the diameter of that cylinder. If the engine works at very slow speeds on domestic service it may be desirable to still further shorten the stroke, and the only limit that it appears necessary to impose is that the number of revolutions on fire service shall not be too great. It may be urged that the work expended in overcoming the inertia of the column of water in the mains would be an argument against many strokes and in favor of few, but in a duplex pump only the water in the cylinder comes to rest during the change of stroke, and the more frequent the stroke the less the fluctuation of pressure in the mains and the less energy used up in accelerating the water column, so that a short stroke will be likely to increase the duty of a duplex compound pump up to a certain limit. Just what this limit will be will depend upon the particular case in hand. While at first sight it may appear that the shortening of the stroke will have a detrimental effect by increasing the clearance, yet this is of comparatively small consequence, as the steam occupying the clearance space in the high pressure cylinder is passed over to the low pressure and does work there, so that all that is really wasted is that in the clearance spaces of the low-pressure cylinder, and this, from its highly expanded condition, will not amount to much. Therefore it seems to us that for such service as that here considered a short stroke is to be looked upon with favor.

ACCORDING to the *Elektro-technische Zeitschrift* the proper height at which electric arc lights should be placed is 0.7 of the radius of the area to be illuminated. While this rule apparently has not been followed in the larger number of installations, it is of interest to note that in more recent work there is a tendency to place the lights at greater heights.

THE Master Plumbers' Association, of Dallas, Tex., are to give a banquet to the delegates to the convention of the Association of Master Plumbers of Texas State, at Dallas, on Thursday, October 23, 1890. D. S. Sullivan is President, and M. F. Kavanaugh is Secretary of the Dallas Association.

THE Masonic Temple to be built at Chicago, will, it is claimed, be the largest building in the world. It will be 18 stories high and have 14 elevators. It is to be finished and ready for occupancy on May 1, 1892.

CONTRACTING NEWS DEPARTMENT.

A WEEKLY RECORD

OF SPECIAL INTEREST TO CONTRACTORS, BUILDERS AND MANUFACTURERS OF ENGINEERING AND BUILDING SUPPLIES.

CONTRACTING INTELLIGENCE

Our readers will oblige us by notes, clippings, or any information which will put us in the way of obtaining early and reliable news for our "Contracting Intelligence." *Information of importance sent to us exclusively, and not elsewhere published will be liberally paid for.*

Persons who make any use of the information they find in these columns we trust will not omit to mention THE ENGINEERING & BUILDING RECORD as the source

For works for which proposals are requested see also the "Proposal Columns," pages i-ii-321.

BUENA VISTA, VA., October 13, 1890.

THIS city is now putting in a system of sewerage, at a cost, when completed, from $25,000 to $35,000. We have fine water-works, and will, in a short while, expend from $20,000 to $50,000 enlarging same. Have ordered hose and hose wagon from Northwestern Rubber Company, and have organized fire department. Our city is 18 months old, and has a population of 2,500, and in 12 months will number 10,000.

C. BARGAMIN,
Superintendent Water-Works.

WATER.

For Additional Water Items see Proposal Columns.

NEW ALBANY, IND.—It is estimated that the reservoir about to be constructed by the water-works company on the Silver Hills will cost $30,000.

ROCKFORD, ILL.—The water-works will bore two or three more artesian wells, 1,300 feet deep, next season.

BABYLON, N. Y.—The people of this place voted to establish a system of water-works at an election held October 11. The matter is to be further considered at the next meeting of the Town Board.

ST. LOUIS, MO.—The contract for the 20,000,000-gallon high-duty vertical pumping engine has been awarded to H. R. Worthington, New York, at $299,500.

MADISON, N. J.—Concerning the water-works here, Samuel B. Leach, hydraulic engineer writes: "The works were designed by me, and are being constructed under my supervision and superintendence as engineer, by Moffett, Hodgkins & Clark as contractors, Mr. O'Geran having immediate charge of the work for the contractors."

WAYNE, NEB.—It is proposed to begin at once on the proposed system of water-works for this place, for which the sum of $18,000 has been appropriated.

DALLAS, TEX.—Press dispatches state that an abundant flow of pure artesian water has been struck at this place and that immediate efforts are to be made to utilize it.

WESTFIELD, PA.—J. H. Miller, of this place, writes: "A company, with a capital stock of $25 000, has been organized at this place, with myself as president, for the purpose of establishing a system of water-works. The company expects to complete arrangements during the winter, so as to begin operations as soon as spring opens."

EDDY, TEX.—The Town Clerk at this place writes: "The question of water-works has been entertained at this place, and proposals of different companies have been and are being made. The stock company has fixed a limit of capital stock at $2,000. As yet no contract has been negotiated, and may not be this fall."

ELWOOD, IND.—It is proposed to expend the sum of $20,000 on a system of water-works for this place.

NORTH BROOKFIELD, MASS.—At a meeting of the taxpayers of this place all were agreed that a supply of water should be introduced into town for fire and mechanical purposes, such water being first secured as could, if necessary, be used for domestic purposes. Fifty thousand dollars was agreed to be the limit of expense which should be incurred, to be paid by the town in the course of 10 years. The question is to be further considered at a meeting to be held October 21.

LEBANON CITY, MO.—The water-works franchise granted by the Lebanon City Council to the light and water company has been ratified at the polls.

BAY CITY, MICH.—The question of expending $50,000 on water-works improvements is to be decided by vote at the election in November.

FORT WAYNE, IND.—The sum of $22,000 is to be expended on new water mains for this place.

AUSTIN, GA.—It is stated that a quantity of iron pipe, iron tanks, plugs, etc., will soon be wanted at this place, and that W. J. Dobbs can furnish particulars.

PLAQUEMINE, LA.—The people of this place will hold a mass meeting in a few days to discuss the water-works question.

ESTHERVILLE, IOWA.—The water-works question at this place is to be settled by a public vote. For particulars address A. O. Peterson, Chairman of Fire and Water Committee, as above.

EXIRA, IOWA.—It is proposed to expend $3,000 on a system of water-works for this place.

SAN ANGELO, TEX.—City Clerk John Moorkens writes: "Contract for a new system of water works has been granted to J. L. Millspaugh, President San Angelo Water-Works Company, for 15 years."

FLATONIA, TEX.—City Secretary H. S. Palmer writes: "The City Council has authorized bonds to be issued, not to exceed $30,000, which are to be used in putting in water-works, or so much thereof as will be found necessary."

KIRKWOOD, MO.—H. W. Hough, Town Clerk, writes: "There have been no steps taken to establish water-works in this locality."

HOMESTEAD, PA.—The following report was submitted by the Water-Works Commissioners appointed to take action in regard to the construction of a water-works at this place. That the work be commenced in the spring of 1891, and completed by the fall of the same year. As the result of advertisements the following bids were received: Chester B. Davis, Chicago, Ill., 5 per cent, of cost of works; Julien Kennedy, Pittsburg, Pa., 5 per cent. of cost of works; Fred. T. Crane, East Orange, N. J., $600 for plans and specifications, $150 per month; Samuel B. Leach, Tarrytown, N. J., 3½ per cent. of cost of the works; J. Schinneller, Pittsburg, Pa., 4½ per cent. of cost of the works. The bid of engineer Schinneller was accepted, because he is a local resident, and it was believed that he could, therefore, give most satisfactory services, he was accordingly ordered to prepare plans and specifications. J. M. Hoover is Chairman of Water Committee.

LINCOLN, ILL.—City Clerk John H. Starkey writes: "We have a system of water-works here since 1886, which are very good. There has been some talk of a new company but no steps have been taken yet."

CINCINNATI, O.—At a meeting of the Board of Public Improvements, held October 14, Superintendent Tharp recommended the construction of a new 6,000,000-gallon pumping engine. The matter was referred to the Committee on Water-Works.

WATER-WORKS.—See our Proposal Columns for information regarding water-works and water-works furnishings at the following places: Toronto, Can.; Markham, Ont.; Carthage, O.; Keithsburg, Ill.; Belvidere, Ill.; Rushville, Ind.; Philadelphia, Pa.

BRIDGES AND IRON STRUCTURES.

For Additional Bridge Items see Proposal Columns.

LA FAYETTE, GA.—The following bids for the building of an iron bridge across West Amichee Creek, were received by R. N. Dickerson, October 7: George H. Crafts, Atlanta, Ga., $1,908; Southern Bridge Co., Birmingham, Ala., $2,100; King Iron Bridge and Mfg. Co., Cleveland, O., $1,895; The Berlin Iron Bridge Co., East Berlin, Conn., $2,150; W. H. Converse, Chattanooga, Tenn., $1,875; The Columbus Bridge Co., Columbus, O.,$2,076; Milwaukee Bridge and Iron Works, Milwaukee, Wis., $1,930; Pittsburg Bridge Co., Pittsburg, Pa., $1,958.

SAN ANTONIO, TEX.—The following bids for the construction of a through truss class "A" bridge on San Antonio River, were received by Mayor Bryan Callaghan. October 4: Wrought Iron Bridge Co., Canton, O., $17,581; Thomas Murray & Co., New York, $15,500; George E. King Bridge Co., Des Moines, Iowa, $17,980; Berlin Iron Bridge Co., Berlin, Conn., $13,000; Pittsburg Bridge Co., Oliver, Penn., $18,400; Penn Bridge Co., Beaver Falls, Pa., $17,190; Variety Bridge Co., Cleveland, O, $15,100; Milwaukee Bridge and Iron Works, Milwaukee, Wis., $16,000; Smith Bridge Co., Toledo, O., $18,300; Mt. Vernon Bridge Co., Mt. Vernon, O., Plan A, $13,500; Plan B, $15,000; Lane Bros. Bridge and Construction Co., Newark, O., $16,004; Missouri Valley Bridge and Iron Works, $15,000; Chicago Bridge and Iron Co., $17,000; Wisconsin Bridge and Iron Co., Milwaukee, Wis., Plan A, $14,700; Plan B, $14,300; Lane Bridge and Iron Works, Chicago, Ill., $16,809; King Iron Bridge Mfg. Co., Cleveland, O., $17,952.

CLEVELAND, O.—It is proposed to erect a new bridge in this city over the "Central Way." Address the City Engineer for particulars.

BOSTON, MASS.—Estimates and general plans are being made by the engineer's department for a bridge, etc., over the Providence Division of the Old Colony Railroad at Forest Hills, in order to abolish the present grade crossing. Exclusive of land damages, the cost will be about $52,000.

NAPA CITY, CAL.—City Engineer Buckman has been instructed to procure plans and estimates for a new bridge over the river at Third Street.

SAGINAW, MICH.—Repairs are to be made to the bridges at Mackinaw and Johnson Streets.

KANSAS CITY, MO.—The Board of County Commissioners has authorized the erection of a bridge on the Leavenworth County line, in Prairie Township.

SPOKANE FALLS, WASH.—The City Council has issued bonds in the sum of $25,000 for the purpose of constructing a bridge at this place.

WILLIMANSETT, MASS.—A new bridge is to be constructed here after plans, just finished, by Edward S. Shaw, of Boston, Mass.

LANCASTER, PA.—It is proposed to repair all the county bridges at once.

SAN FRANCISCO, CAL.—It is proposed to either repair the Second Street bridge or to replace it with a new structure. For particulars, address Superintendent Ashworth, of the Street Committee, as above.

MILWAUKEE, WIS.—The plans for the new bridge on North Avenue have been completed by the City Engineer. According to the specifications the structure will be 522 feet in length, exclusive of the abutments, and 30 feet above the surface of the water. The entire bridge, with the exception of the planking of the roadway, will be of iron and steel. The cost is estimated at about $30,000. The Whitefish Bay Railway Company will erect the bridge, but the city will reimburse it for one-half of the expense.

PHILADELPHIA, PA.—A petition has been presented to Councils for a bridge over the Pennsylvania Railroad on the line of Oxford Street. Particulars can be obtained by addressing Clifford Pemberton, Jr., of this city.

BAYONNE, N. J.—Two bridges are to be erected at this place by the Central Railroad of New Jersey.

VICKSBURG, MISS.—Assistant Engineer John Ewans, appointed to examine and report on the proposed site of the New Orleans and Northwestern Railroad bridge over Bœuf River near Rayville, reports favorably. The bridge will open 60 feet in the clear, and is situated two miles north of Rayville.

LITCHFIELD, CONN.—It is proposed to erect a new iron bridge at the East Mill.

NEW LONDON, CONN.—A new bridge is to be erected over Winthrop's Cove, this city.

AUSTIN, TEX.—It is proposed to establish a new iron bridge at this place.

ST. PAUL, MINN.—At a meeting of the Board of Public Works, held October 10, all the bids for the superstructure of the Sixth Street bridge were rejected. The following were the bidders: Keystone Bridge Company, $136,000; Chicago Forge and Bolt Company, $126,160; Milwaukee Bridge and Iron Works, $136,000; Chicago Bridge and Iron Company, $149,999; King Iron Bridge and Manufacturing Company, $141,000; New Jersey Steel and Iron Company, $133,400. The engineer's estimate of the cost of the work was $133,000. It is stated that the bid of the Chicago Forge and Bolt Company would have been accepted but for the fact that all the sureties offered were non-residents of Minnesota, and the law requires that such shall be residents.

SCRANTON, PA.—City Clerk M. T. Lawler writes: "At the election on November 4, the question of increasing the indebtedness of the city $250,000, for the purpose of constructing four bridges, will be voted on by the electors."

BALTIMORE, MD.—City Clerk A. E. Smyrk writes: "The only bridge work now contemplated by the city is an iron bridge over the Baltimore and Ohio Railroad, on line of Monroe Street."

CHATTANOOGA, TENN.—A terminal company has been organized in the city, and among the works contemplated is the erection of a double-track railroad bridge, with footways on each side, to span the Tennessee River. Work is to be commenced on the structure at once.

LITTLE BRITAIN, PA.—On the 23d of October a jury appointed by the Court will meet for the purpose of viewing a site for an inter-county bridge over the Octaroro, from this place to Lower Oxford.

CHICAGO, ILL.—The Chicago and Western Indiana Railway Company will build an iron bridge, to cost between $40,000 and $50,000, over the Little Calumet River near Dalton, Ill. S. H. Miller, civil engineer, will have charge of the work.

LOCKPORT, ILL.—R. D. Wheaton & Co., of Chicago, have been awarded the contract for the construction of an iron bridge at this point, at $9,595.

THE Editor of THE ENGINEERING AND BUILDING RECORD is always glad to receive items of news for the Contracting News Department. But such items are not considered news except when the prices and particulars of the award of a contract are given.

The announcement that ——— has sold ——— to ——— without giving the *prices* and particulars concerns only the buyer and seller. Such notices are always excluded, except in the case where a certain firm is stated to have taken a certain contract, the execution of which would require that they should buy certain materials. Such an item would be used if deemed of more than local interest, because it would suggest to some readers the possibility of their making a sale or securing a sub-contra

DAYTON, TENN.—Two iron bridges are to be erected by the Tennessee Industrial Land Company of this place.

CLINTON, ILL.—Reports say that the Chicago and Eastern Illinois Railroad Company will replace its present wooden bridge at this place with a steel one, and that next year iron and steel structures will replace every wooden bridge on its system.

PITTSBURG, PA.—A new bridge is to be erected over the Susquehanna River by the Erie and Wyoming Railroad Company.

ORANGE GROVE, FLA.—Reports say that it has been decided to expend the sum of $22,000 on a bridge to span the Patapsco River at this place.

PHILADELPHIA, PA.—Plans have been received by the Park Department for a $50,000 iron bridge over Lansdowne Ravine.

BRIDGES.—See our Proposal Columns for information regarding bridge construction at the following places: Dublin, Ga.; Augusta, Ga.; Atlanta, Ga.; St. Paul, Minn.; Philadelphia, Pa.; Greensburg, Pa.; Zanesville, O.

NEW DEPOTS.

MORRISTOWN, PA.—The Reading Railroad Company will erect a large depot at the corner of De Kalb and Washington Streets, in this city.

KANSAS CITY, MO.—Van Brunt & Howe, architects, of this city, with J. A. L. Waddell, as consulting engineer, have prepared plans for a new union depot at Sioux City, Iowa.

MANASQUAN, N. J.—A new depot is to be erected here by the New York and Long Branch Railroad Company.

DES MOINES, IOWA.—The Iowa Railroad Commissioners have issued an order directing the Chicago, Milwaukee and St. Paul Railroad to build at once a commodious freight and passenger depot, and furnish other facilities at the station of Denison, Iowa.

WILKENSBURG, PA.—It is reported that the Pennsylvania Railroad will erect a new freight depot at this place.

ERIE, PA.—According to reports, John Hanchett has been awarded the contract to erect a new depot at this place.

CHESTER, PA.—A new depot is to be erected at this place by the Pennsylvania Railroad Company.

THE CONTRACTING NEWS DEPARTMENT of **THE ENGINEERING AND BUILDING RECORD** is edited with a view of giving space to no item that does not indicate where professional services or supplies may be needed in the near future, the prices bid for work or supplies, and the correction of false or misleading reports in some papers, that may subject readers to needless trouble and expense in going after something that does not exist.

SEWERAGE.

For Additional Sewerage Items see Proposal Columns

ATLANTA, GA.—The Aldermanic Board has concurred in the action of the City Council authorizing ordinances to be drawn providing for the extension of the main sewers to the city limits. It is probable that the matter will come up at the next meeting of the Council, and acted on.

ROANOKE, VA.—Important sewer work is projected here.

SCRANTON, PA.—Operations will probably soon begin on the $75,000 sewer job at this place.

WASHINGTON, PA.—A committee of citizens has been appointed at this place to take steps towards establishing a system of sewers.

JAMESTOWN, N. Y.—The sum of $95,000 has been appropriated at this place for the purpose of establishing a system of sewers.

SAN FRANCISCO, CAL.—It is proposed to construct sewers in the district north of the park, in this city. For particulars, address the City Engineer, as above.

DAYTON, O.—The following proposals for the construction of sewers in this city were opened October 13 by the City Engineer:

BIDDERS.	PIPE LAID, PER LINEAL FOOT.							DRAIN TILE LAID, PER LINEAL FOOT.				BRICK SEWER, PER LINEAL FOOT.				EXCAVATION, PER LINEAL FOOT.								Repaving, each.	Manholes, each.	Lampholes, each.	Flush-tanks.	Iron Pipe, price in tons, each.	Embankment, Cubic yards each	Clay Puddle, Cubic yards, each.	Total Bids.

SAGINAW, MICH.—The City Engineer has been instructed to prepare plans for numerous new sewers.

COLUMBUS, GA.—An election will be held in Columbus some time next month for the purpose of determining whether the city shall issue bonds to put in a separate system of sanitary sewerage. Plans and specifications for the new system of sewerage have been made, and the estimated cost is $125,000.

TROY, N. Y.—The Public Improvement Commissioners have authorized the construction of numerous sewer extensions.

LORIN, CAL.—The local improvement association is agitating the question of establishing a system of sewers at this place.

TORONTO, CAN.—City Engineer W. T. Jennings has recently been visiting Boston inspecting the system of sewerage of the latter city, having in view the introduction of a new system of intercepting sewers for Toronto.

NEW PHILADELPHIA, O.—This city contemplates establishing a system of sewers.

SEWERS.—See our Proposal Columns for information regarding sewer construction at the following places: Jersey City, N. J.; Avondale, O.; Detroit, Mich.; Albuquerque, N. M.

STREET-WORK AND PAVING.

AURORA, ILL.—This city has decided to pave its principal streets with cedar blocks.

ROCKFORD, ILL.—The principal streets will be paved next season. The City Engineer is D. C. Dunlap.

SAN FRANCISCO, CAL.—It has been decided to put all the streets along the water front of this city in good condition.

SCHENECTADY, N. Y.—Many of the streets of this place are to undergo extensive improvements.

CHESTER, PA.—Numerous streets of this place are to be repaved at an early date. Address the City Engineer for particulars.

ROANOKE, VA.—Extensive street improvements are to made at this place.

ST. PAUL, MINN.—The Board of Public Works will report favorably upon the paving of numerous streets of this city.

NEW PHILADELPHIA, PA.—Considerable street paving is to be done at this place.

CHATTANOOGA, TENN.—Several streets of this city are to be widened, repaved and extensively improved.

BROOKLYN, N. Y.—City Works Commissioner Adams has authorized that proposals be issued for paving, curbing and guttering, with Belgian block and bluestone, several streets of this city.

GAS AND ELECTRICITY.

CAIRO, ILL.—The Citizen's Electric Light and Power Company has accepted the ordinance granting it permission to erect its power house, poles, etc., and to suspend the necessary wires for furnishing the patrons of the company with electric light and power.

KEOKUK, IOWA.—The Gate City Electric Company has been incorporated at this place. Capital stock, $150,000. George D. Rand is at its head.

PLAQUEMINE, LA.—It is probable that an electric lighting system will be established at this place.

ALEXANDRIA, LA.—The City Council has made a contract with the Thomson-Houston Electric Company to furnish the town with electric lights.

NEWBURG, N. Y.—Extensions are to be made to the local electric light plant.

ST. PAUL, MINN.—The Continental Dynamo Company has been awarded the contract for the electric light plant for the High School, for $1,550.

JAMESTOWN, N. Y.—The people of this place have voted $30,000 for electric lights.

UPLAND, PA.—Reports say that when the present contract for public lighting expires at this place an effort will be made to introduce electric lights.

NEW ROCHELLE, N. Y.—For lighting the village streets the Trustees have recommended the payment of $125 per year for each arc light, $25 each for 100 incandescent lights, and $25 each for 100 gas lights.

KEOKUK, IOWA.—At a meeting of the City Council, held October 7, the bids for lighting the city were opened. The following were the bidders: Keokuk Electric Light and Power Company, Badger Electric Company, Gate City Electric Company, Keokuk Gas Light and Coke Company. The figures for electric lighting were made on a basis of furnishing 125 arc lights of 2,000 candle-power each, the Philadelphia system to prevail. The highest bid was that of the Badger Electric Company, whose bid was $72 per light per year, with conditional figures for more or less lights. The lowest bid was that of the Gate City Electric Company, which was $60 per light per year, with conditions the same as above. The Keokuk Electric Light and Power Company's bid was $68 per light. The bid of the Keokuk Gas Light and Coke Company was as follows: For furnishing 100 gas street lamps, under the Philadelphia schedule, $25 a year, with additional lamps at $22. The figures in detail of the lowest bidder were as follows: Gate City Electric Company, first, to furnish 125 arc lights on the Philadelphia schedule, at $60; additional lights at $60; 125 arc lights and additional arc lights at $60. Second, 125 arc lights every night up to 12 o'clock at $60; additional lights at $60; 125 lights and additional lights at $60. Third, 125 arc lights every night and all night at $75; additional lights at $75; 125 lights and additional lights at $75. Fourth, 100 arc lights on the Philadelphia schedule at $65; additional lights at $65. Fifth, 100 arc lights every night up to 12 o'clock at $65; additional lights at $65; 100 lights and additional lights at $65. Sixth, 100 arc lights every night and all night at $78; additional lights at $78; 100 lights and additional lights at $78. Seventh, 60 arc lights on the Philadelphia schedule at $75; additional lights at $75; 60 lights and additional lights at $75. Eighth, 60 arc lights every night up to 12 o'clock at $75; additional lights at $75; 60 lights and additional lights at $75. Ninth, 60 arc lights every night and all night at $84; additional lights at $84; 60 lights and additional lights at $84. The company further agrees that in case a contract is awarded to it for 125 arc lights, to be lighted under the Philadelphia schedule, it will furnish same on such moonlight nights as may be necessary by reason of cloudiness, without additional cost to the city.

ORANGE, N. J.—The Essex County Electric Light Company has decided to build an incandescent light system for houses.

NORTH PLAINFIELD, N. J.—A committee has been appointed to procure electric lighting for this place.

EAST AURORA, N. Y.—This place is soon to have electric lights.

TORONTO, CAN.—The Fire and Gas Committee has awarded the following contracts for public lighting: Toronto Electric Light Company, for the supply of from 800 to 1,200 arc electric lights for five years, at 29¾ cents each per night; Consumers' Gas Company, for the supply of a minimum of 1,000 lamps with 4-foot burners, on the present line of mains, in such localities as may be required by the city, at $21.50 each per annum; Lambeth lamps at $75 each per annum, and such lamps as may be required on new mains, a distance of 150 feet apart, at $23 each for lamps with 4-foot burners, and $75 each for Lambeth lamps.

PORT JERVIS, N. J.—The plant of the local gas light company is to be extended.

BELLAIRE, O.—The Gearing Fuel Gas Company has been incorporated at this place. J. M. Waring can furnish particulars.

ATLANTA, GA.—Reports say that an electric light plant is to be erected in this city by the Georgia Electric Light Company.

RED CLIFF, CAL.—The Fall Creek Electric Company is to establish an electric light plant at this place. Estimated outlay, $10,000. For details, address G. F. Brock, as above.

FAIRFIELD, IOWA.—This place is to have electric lights. For details, address C. D. Jones, as above.

MONTGOMERY, ALA.—The Ball Light and Power Company has been incorporated at this place, and an electric light plant will be established. For particulars, address P. B. Bibb, as above.

DERRY, PA.—A plant is to be established at this place by the Derry Electric Light Company, at an estimated cost of $5,000.

COHOES, N. Y.—Improvements are to be made to the local electric light plant.

Electric Railways.—New electric railways are to be constructed, and improvements are to be made to those already established at the following places: Worcester, Mass.; Roanoke, Va.; Springfield, Mass.; Knoxville, Tenn.; Cairo, Ill.; Media, Pa.; Chester, Pa.; Salem, Mass.; Lewiston, N. Y.; Reading, Pa.; San Francisco, Cal.; Hannibal, Mo.; Middletown, Conn.; Jersey City, N. J.; Wheeling, W. Va.; Lynn, Mass.; Paducah, Ill.

BIDS OPENED.

Kansas City, Mo.—All the bids for building the Masonic Temple have been rejected, as they were over the limit, and the work is to be re-advertised.

Flushing, L. I.—The contract for macadamizing the North Hempstead Turnpike has been awarded to Thomas F. Tuohy and Company, of this place, at $65,000.

New York.—William J. Baldwin, heating and ventilating engineer and contractor, has the contract for warming and ventilating the Sims Clinic in connection with the College of Physicians and Surgeons, New York. W. Wheeler Smith, architect.

Brooklyn, N. Y.—The contract for heating the new building of the Brooklyn Polytechnic Collegiate Institute, by hot-water circulation, has been awarded to G. C. Blackmore, Newark, N. J., at a total cost of $15,000. Four No. 9 perfect water heaters will be used, with 13,000 square feet radiation.

Duluth, Minn.—Wilford & Northway, of Minneapolis, have secured the contract for the machinery for the Duluth Milling Company's new flour mill, to be erected here at once. J. H. Malloy has secured the contract for the construction of the mill and accessories. The mill will be of brick and stone, to cost $225,000.

Peru, Ill.—The contract for heating and ventilating the new monastery here has been awarded to Robert Clark, steam heating engineer, of Peoria, Ill., for $11,000.

GOVERNMENT WORK.

Tompkinsville, N. Y.—Abstract of bids received by Major D. P. Heap, U. S. A. Engineer, Third Lighthouse District, October 11, for furnishing 500 tons rip-rap stone at Saybrook Breakwater Light Station, Conn: Wm. H. Molthrop, New London, Conn., granite, $1.65; Charles F. Stoll, New London, Conn., granite, $1.49; T. A. Scott, New London, Conn., granite, $1.75, brownstone, $1.35, Daniel Crowley, New London, Conn., granite, $1.19; James Scully, Groton, Conn., granite, $1.75; John Beattie, Leetes Island, Conn., granite, $1.25; Connecticut River Granite Company, Essex, Conn., granite, 93 cents; James V. Luce, Niantic, Conn., granite, $1.39, Telegram, less 5 cents per ton from the quoted price.

Washington, D. C.—The following proposals for the work specified were opened on the given dates by the Supervising Architect of the Treasury Department:

Williamsport, Pa. — Low-pressure steam heating and ventilating apparatus for the United States Court-House and Post-Office at this place. Opened October 10. Bidders: James & R. H. Walker, Elmira, N. Y., $7,300; John Lyon, Washington, D. C., $8,295; Crook, Horner & Co., Baltimore, Md., $8,398.15; Samuel I. Pope & Co., Chicago, Ill., $8,478; Blake & Williams, New York, $9,980; Q. N. Evans Construction Co., New York, $10,289; E. Keeler & Co., Williamsport, Pa., $10,800; Williamsport Steam Co., Williamsport, Pa., $11,610.

Charlotte, N. C.—Low-pressure heating and ventilating apparatus for the United States Court-House and Post-Office at this place. Opened October 15. Bidders: J. E. Tinsley, Charlotte, N. C., $5,934; John Lyon, Washington, D. C., $6,180; Crook, Horner & Co., Baltimore, Md , $6,699.78; Samuel I. Pope & Co., Chicago, Ill., $7,963; Blake & Williams, New York, $8,891.

Readers of **THE ENGINEERING AND BUILDING RECORD** interested in the Contracting News Department of that paper are respectfully requested to examine those columns every week, and advise the Editor of any item which they may find that, in their judgment, is of no value to any one other than the person mentioned.

INDUSTRIAL.

Toronto, Ont.—The City Commissioners' report, that tenders be advertised for for a crematory to consume 75 tons of garbage and 20 tons of night soil, has been adopted.

Boston, Mass.—The sum of $840,000 has been appropriated by the Finance Committee of the City Council for public improvements.

PROPOSALS.

(Continued from page ii.)

PROPOSALS FOR CONSTRUCTION.—U. S. Engineer Office, 89 Euclid Avenue, Cleveland, O., October 14, 1890.—Sealed proposals, in duplicate, will be received at this office until 12 o'clock M. on MONDAY, November 3, 1890, when they will be opened in presence of bidders, for constructing 450 lineal feet, more or less, of the structure of east **BREAKWATER** at CLEVELAND, O. All information can be obtained at this office. The United States reserves the right to reject any or all proposals. Preference will be given to materials and plant of domestic production or manufacture, conditions of quality and price (import duties included) being equal. The attention of bidders is invited to the Acts of Congress, approved February 26, 1885, and February 23, 1887, Vol. 23, page 332, and Vol. 24, page 414, Statutes-at-Large. L. COOPER OVERMAN, Major of Engineers. 22

PROPOSALS FOR DREDGING. — UNITED States Engineer Office, Cleveland, O., October 14, 1890.—Sealed proposals, in duplicate, will be received at this office until 12 o'clock M. on MONDAY, the 3d day of November, 1890, and then opened, for **EXCAVATING** 240,000 cubic yards, more or less, of material from SANDUSKY BAY along line of proposed straight channel for Sandusky Harbor, O. Preference will be given to materials and plant of domestic production or manufacture, conditions of quality and price (import duties included) being equal. The attention of bidders is invited to Acts of Congress approved February 24, 1885, and February 28, 1887, Vol. 23, page 332, and Vol. 24, page 414, Statutes at Large. All information can be obtained at this office. The United States reserves the right to reject any or all proposals. L. COOPER OVERMAN, Major of Engineers. 22

OCTOBER 14, 1800.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M. on the 3d day of November, 1890, for all the labor and materials required for the **PLUMBING** and gas-piping for the U. S. Post-Office building at DAYTON, O., in accordance with the drawings and specification, copies of which may be had on application at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $100. The Department will reject all bids received after the time herein stated for the opening of the same; also, bids which do not comply strictly with all the requirements of this invitation. Each proposals must be inclosed in an envelope, sealed and marked "Proposal for the Plumbing and Gas-Piping for the U. S. Post-Office, etc., at Dayton, O.," and addressed to JAS. H. WINDRIM, Supervising Architect. 21

HEADQUARTERS SOUTHERN BRANCH, National Home for D. V. Soldiers, Hampton, Va., October 14, 1890.—Sealed proposals, subject to the usual conditions, will be received at this office until twelve (12) o'clock, noon, THURSDAY the thirtieth (30) day of October, 1890, for **BREAKWATER** at the Southern Branch of the National Home for D. V. Soldiers, near Hampton, Va. The work to consist of Piling Revetment, Dredging, Embankment and Platform, etc. Specifications and drawings can be seen at this office and further information obtained from the Governor of the Home. WM. C. GUNNELL, Civil Engineer. 21

OCTOBER 16, 1890.

SEALED PROPOSALS WILL BE RECEIVED at the office of the Supervising Architect, Treasury Department, Washington, D. C., until 2 o'clock P. M. on the 11th day of November, 1800, for all the **LABOR AND MATERIALS** required for the approaches to the U. S. Court-House, Post-Office, etc., building at LOUISVILLE, KY., in accordance with the drawing and specification, copies of which may be had on application at this office or the office of the Superintendent. Each bid must be accompanied by a certified check for $500. The Department will reject all bids received after the time herein stated for the opening of the same; also, bids which do not comply strictly with all the requirements of this invitation. Proposals must be inclosed in an envelope, sealed and marked, "Proposal for the Approaches to the U. S. Court-House, Post-Office, etc., building at Louisville, Ky.," and addressed to JAS. H. WINDRIM, Supervising Architect. 21

BRIDGE WORK, Greensburg, Pa.—Proposals are wanted until October 27, for a new superstructure and repair to the masonry work of a low truss iron bridge at this place. Address John M. Young, Clerk to the Commissioners, as above.

McDonough st, s s, 175 e Ralph av, 8 b and red s dwells; cost, $4,000 each; o and a, Thomas H Radcliffe; b, J Covert.

6th st, s s, 126 w 4th av, 4 br tens; cost, $8,500 each; o, M Blanthorn; a, G M Miller; b, C Trimble.

MISCELLANEOUS.

CHAMBERSBURG, PA.—Work will soon be begun on the new machine shops of the Cumberland Valley Railroad. The machine and erecting shops will each be 50x150 feet. The other building will be 50x200 feet. The material will be brick. The company will advertise for bids in a short time.

BUILDING INTELLIGENCE.

ALLEGHENY, PA.—Mulberry st, 4-story br building for workshop; cost, $10,000; o, Coffin Works; a, Alston & Heckert; b, W F Trimble.

CANAL DOVER, O.—The Reeves Iron Co, of this place, will erect a large pipe works, in connection with their rolling plant, the city having donated $30,000.

DENVER, COL.—Col. W. K. Gooch and W S. Alkire will build a $30,000 block.

DETROIT, MICH.—Michigan av, bet Harrison and National avs, 4 3-story br stores and flats; cost, $16,000; o, Jas H Pound; a, E A Walshe & Son; b, not let.

Ferry av, west of St Antoine st, 2½-story br res; cost, $8,500; o, R J Wilson; a and b, same as above.

Ferry av, bet Woodward av and John R sts, 2-story res; cost, $45,000; o, C L Freer; a, John Scott & Co; b, same as above.

Locust st, bet Trumbull and National avs, 5 2-story fr res; cost, $12,500; o and b, Fred Gibson.

Third av, bet Walter and Holden avs, 3-story br double res; cost, $9,000; o, H W Holcomb; a, Harry J Rill; b, not let.

DUQUESNE, PA.—The Catholic Slavonic Congregation will erect a $10,000 church at this place.

FOREST CITY, PA.—A large hotel is to be erected at this place by R W Taylor.

LANCASTER, PA.—Two school buildings; cost, $25,000 each; b, contract not let.

LANSING, MICH.—Washington av, 3-story br office bldg; cost, $10,000; o, Geo E Ranney, M D; a, E E Myers, Detroit.

LEOMINSTER, MASS.—Stone church; cost, $20,000; o, Baptist Society.

LITTLE ROCK, ARK.—Lincoln av, 3 br houses; cost, $15,000; o, Jas R Miller; a, Fred J H Rickon; b, not let.

LANCASTER, PA.—Several new school buildings are to be erected in this city.

MINNEAPOLIS, MINN.—A theater, to cost $75,000, is to be erected on 1st avenue, between Washington and 3d streets, by Ralph Rees.

1908 Portland av. fr dwell; cost, $10,000; o, J M Bartlett; a, Orff Bros.

MINNEAPOLIS, MINN.—2425 S Emerson av. fr dwell; cost, $8,000; o and b, J P Larson; a, F Hoover.

2538 Stevens av, br stores and flats; cost, $22,000; o, Andrew Haugan; a, W H Dennis.

Tyler st and 14th av N E, br linen mill; cost, $25,000; o, Minneapolis Linen Co; a, W H Hayes; b, H N Leighton & Co.

NEWARK, N. J.—The State Board of Education has approved the plans for the new Normal School building, drawn by L H Broome, of Jersey City, N. J.

Plans have been prepared for the new addition to the County Insane Asylum, by Staehlin & Steiger, architects, of this city. The cost is estimated at $20,000.

PHILADELPHIA, PA.—S s Yotk st, w Sedgeley st, machine shop; b, R Smedley.

S s Gasker st, w 21st st, 16 dwells; o, W McCarter.

N s Sansom st, w 6th st, bldg; o, W C McPherson & Son.

S w cor 63d and Hamilton sts, church; b, J R Wiggins.

W s Maschers st, 8 e Mutter st, 15 dwells; o, E J Develin.

N s Asylum Pike, e Olney st, club house; o, E K Welch.

E s Clinton st, n Baker st, 16 dwells; b, McLaughlin & Co.

W s 3d st, s Venango st, factory; o, Payne Varnish Co.

S s Ruay st, e Edward st, 16 dwells; b, W H Gelland.

Bridge st, nr Orchard st, factory; o, R O Moorhouse.

S e cor Shedwick st and Ginter av, library; b, Martin Hetzel.

N w cor Dock and Pear st, factory; b, Thos Little & Sons.

BUILDING INTELLIGENCE.

ROCKFORD, ILL.—P. G. Hollem will build a row of flats on 5th street.

READING. PA.—The congregation of the First Baptist Church of this place contemplate erecting a new church.

ROCKFORD, ILL.—The Catholics will build a school-house here, to cost about $10,000.

WARREN, O.—Corner of Franklin and Main, S W; 3-story br bldg; cost, $10,000; o, J W Biggers; a, J P Leach; b, not let.

BUILDINGS.—There is nothing over $7,000 in value to report at the following places · Cambridge, O.; Wilkes-Barre, Pa.; Montclair, N. J.; St. Paul, Minn.; Chester, Pa.; Geneva, N. Y.; Pottsville, Pa.; Wheeling, W. Va.; Ogdensburg, N. Y.; Charleston, S. C.; Clinton, Iowa; Braintree, Mass.; Poughkeepsie, N. Y.; Canton, O.; Cambridge, O.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

NOW APPEARING IN THE ENGINEERING AND BUILDING RECORD.

I.—Introduction. Issue of November 27, 1886.

II., III., IV.—Erection of the Towers of St. Patrick's Cathedral in New York City. Seven Illustrations. Issues of December 4, 11, and 18, 1886.

V.—Improvements in Dredging Machinery. Thirteen Illustrations. Issue of December 25, 1886.

VI.—Dumping-Scows. Thirteen Illustrations. Issue of January 1, 1887.

VII., VIII., IX., X., XI.—The Equitable Building in New York City. Thirteen Illustrations. Issues of January 8, 22, 29, February 5 and 12, 1887.

XII.—Carson's Trench Machine. Four Illustrations. Issue of February 19, 1887.

XIII.—Raising the Old Court-House in Boston. Three Illustrations. Issue of March 5, 1887.

XIV.—Cram's Steam Pile-Hammer. Five Illustrations. Issue of March 12, 1887.

XV.—The Equitable Building, New York City. Three Illustrations. Special Hoisting Engine and Derrick. Issue of March 26, 1887.

XVI.—The Equitable Building, New York City. One Illustration. Shoring of Column. Issue of April 9, 1887.

XVII.—Bridge-Erecting and Hoisting-Engine used on the Suburban Elevated Railway, New York City. Three Illustrations. Issue of April 30, 1887.

XVIII.—Traveler for Erecting Columns and Transverse Girders, Kings County Elevated Railway, Brooklyn, N. Y. Four Illustrations. Issue of June 4, 1887.

XIX.—Excavating Apparatus used on the Tancarville Canal and Sewer, Havre, France. Three Illustrations. Issue of July 2, 1887.

XX.—Tipple Cars on the New Croton Aqueduct. Six Illustrations. Issue of August 13, 1887.

XXI.—Derrick, Foot Block and Sheaves at Shaft 14 on the New Croton Aqueduct. Two Illustrations. Issue of September, 17, 1887.

XXII.—The Potomac Flats Dredging Plant. Nine Illustrations. Issue of October 8, 1887.

XXIII.—The Tube-Riveting Machines at the Forth Bridge. Two Illustrations. Issue of October 22, 1887.

XXIV.—The Lockwood Dredge. Cape Cod Ship Canal. Eight Illustrations. Issue of November 5, 1887.

XXV.—Location of Plant at Shafts on the New Croton Aqueduct. Two Illustrations. Issue of November 12, 1887.

XXVI.—Material Lock used in the Pneumatic Caissons at the Forth Bridge. Illustrated. Issue of December 3, 1887.

XXVII.—Six-Ton Universal Traveling Crane for Elevated Railroad Erection. Illustrated. Issue of December 17, 1887.

XXVIII.—Head-House on the New Croton Aqueduct at Shaft 22. Illustrated. Issue of December 24, 1887.

XXIX.—The New Harlem River Bridge. Illustrated. Issue of January 21, 1888.

XXX.—Erection of Poughkeepsie Bridge, No I. Illustrated. Issue of March 3, 1888.

XXXI.—Oil Rivet Furnace at the Forth Bridge Works. Illustrated. Issue of April 21, 1888.

XXXII.—Erection of Poughkeepsie Bridge. No. 2. Masonry. Illustrated. Issue of May 5, 1888.

XXXIII.—Erection of Poughkeepsie Bridge. No. 3. False Work. Illustrated. Issue of May 12, 1888.

XXXIV.—Erection of Poughkeepsie Bridge. No. 4. Travelers. Illustrated. Issue of May 19, 1888.

XXXV.—Erection of Poughkeepsie Bridge. No. 5. Riveting Traveler, Derrick, and General Plant. Illustrated. Issue of May 26, 1888.

XXXVI.—Erecting Traveler on Kettle Creek Trestle. Illustrated. Issue of June 2, 1888.

XXXVII.—Erection of Central Viaduct, Draw Span, Cleveland, O. Illustrated. Issue of June 9, 1888.

XXXVIII.—The 70-foot Caissons at the Forth Bridge. Illustrated. Issue of June 9, 1888.

XXXIX.—Raising an Engine at Poughkeepsie Bridge erection. Illustrated. Issue of June 16, 1888.

XL.—The Hydraulic Spade at the Forth Bridge Works. Illustrated. Issue of June 30, 1888

XLI.-XLVI.—Harlem River Bridge Erection. No. 2. Masonry. Illustrated. Issue of July 7, 1888.—No. 3. Cement and Concrete. Illustrated. Issue of July 14, 1888.—No. 4. Hoisting Apparatus; Revolving Derrick. Illustrated. Issue of July 21, 1888.—No. 5. Hoisting Apparatus; Floor Travelers. Illustrated. Issue of July 28, 1888.—No. 6. Derrick Details and Shipping. Illustrated. Issue of August 11, 1888.—No. 7. Support of Segments, Field Riveting, etc. Illustrated. Issue of September 1, 1888.

XLVII.—Head-House on New Croton Aqueduct at Shafts Nos. 1. 2. Illustrated. Issue of September 8, 1888.

XLVIII.—Lever Truck for Handling Bridge Material. Illustrated. Issue of September 15, 1888.

XLIX.—Bismarck Bridge. Erecting Traveler. Illustrated. Issue of November 3, 1888.

L.—Details of Head House, New Croton Aqueduct. Illustrated. Issue of November 17, 1888.

LI.—Suspended Tipple for Dumping Cars on the New Croton Aqueduct, N. Y. Illustrated. Issue of December 15, 1888.

LII.—A Viaduct Erecting Traveler. Illustrated. Issue of December 22, 1888.

LIII.—Ropes and Tackle. Illustrated. Issue of December 29, 1888.

LIV.—Power used for Operating Plant on the New Croton Aqueduct. Issue of January 19, 1889.

LV.—Special Methods of Handling Material on the New Croton Aqueduct. Issue of February 16, 1889.

LVI. Railway Bridge Erection in Peru. Part I. The Erection of a 200-foot Span. Illustrated. Issue of February 23, 1889.

SPECIAL OFFERS.

DOUBTLESS many of our subscribers have a friend or friends who think of subscribing to THE ENGINEERING AND BUILDING RECORD for the coming year, and as every paper, however successful it may be, desires to increase the number of its subscribers, the following offers are made, to hold good during October, November and December, 1890:

Any present subscriber can have his subscription extended one year by sending:

One Renewal and One New Subscription	$7.25
" " " Two " "	10.00
" " " Three " "	13.00
" " " Four " "	16.00

The new subscribers will receive, free of charge, the remaining issues of 1890, that is, those which appear after the order is received.

THE ENGINEERING AND BUILDING RECORD,
P. O. Box, 3037. 277 Pearl Street, New York.

THE QUAKER BRIDGE DAM.

IT will be seen by the recent report of the Chief Engineer, A. Ftely, to the Croton Aqueduct Commissioners of New York, upon the subject of the Quaker Bridge Dam, published almost in full in our last number, that this project is at last likely to be abandoned, or, at least, that a dam of much less height, forming a reservoir of materially less storage capacity, will probably be substituted for it.

The matter is not yet positively settled, as the Commissioners have decided to give a hearing upon the subject on the 27th inst. But considering the persistent opposition that the project has met with from a few individuals, almost from its inception, resulting in the repeated postponement of the commencement of work upon it, and in view of the fact that the Chief Engineer has finally thrown the weight of his influence against it, there is little hope that the structure will be built.

The repeated postponement of any decision upon the Quaker Bridge Dam compelled the construction of other, subsidiary dams upon the upper branches of the Croton, in order to get enough immediate addition to the storage to make the new aqueduct of any use in obtaining the much-needed increase in New York's water supply. While the construction of some of these subsidiary dams might have been needed in the future, in order to secure the maximum supply from the Croton, they would not have been required for some time to come; and their construction now, per contra, renders less necessary, for a long time, at least, a reservoir on the lower part of the river of so large a capacity as would have been afforded by the proposed structure. A smaller one, as Mr. Ftely says, will answer, possibly, "for the whole extent to which the supply from the Croton watershed should be properly developed," although he admits that the drainage area would be diminished by about 6 per cent.

It is, unquestionably, the duty of an engineer to resist the temptation to build monumental structures which are not really necessary, however much they may add to his reputation. Considering that this would have been the highest and largest dam in the world, involving considerable difficulty from the depth of its foundations, it is all the more creditable, under the changed circumstances due to the erection of the smaller storage reservoirs, for the chief engineer to modify his previously expressed opinion in favor of the Quaker Bridge Dam, and propose for it a substitute of much less size, and which will cost considerably less money. He gives, as his opinion, that, if the proposed reservoirs on the upper water-shed are built, they, with the proposed substitute on the lower river, would suffice for at least twenty years to come, and that in that time the "accumulated interest on the sum which would be saved by building it at site number 2 would pay for its cost." This is certainly a strong argument for the change.

Since the construction of the smaller dams in the upper water shed had been begun, and the authority to begin work on the Quaker Bridge Dam had thereby been again indefinitely postponed, and the opposition to it being just as persistent, this proposition of Mr. Fteley must be regarded as the next best, and, under the circumstances, most available thing to do.

It is a matter of congratulation that the erection of so important a structure as is even this smaller dam is in such able hands, and that the Chief Engineer will have the co-operation and support of so capable a commission as the existing one. When the clamor about cement begins, charges of favoritism from disappointed contractors will have less weight with the public than they would at one time have had.

WATER-WORKS AND SEWERAGE FOR SMALL TOWNS AND VILLAGES.

AN interesting article on the above subject by Stephen E. Babcock, Chief Engineer of Little Falls Water-Works, is published in the "Fireman's Manual," Watertown, N. Y., 1890. Its object is to advocate the extension of systems of water-works and sewerage to small towns and villages—primarily on account of the advantages accruing to the health of the inhabitants from an abundant supply of pure water, and from having all household slops and fæcal matter removed promptly from the vicinity of dwellings to a suitable point of disposal; and, secondarily, from the increased fire protection obtained, and consequent reduction in rates of insurance. Mr. Babcock also undertakes to show that these great advantages can be obtained without a prohibitive cost, even in villages of a small number of inhabitants.

It is too apt to be the case in small towns, and even in some small cities, that water-works are built without any sewerage system whatever being provided for, or, perhaps, even contemplated, and the increased consumption of water, due to its greater abundance and to the convenience in drawing it, make it still more difficult to dispose of household wastes by the old-fashioned and primitive methods. Mr. Babcock computes the losses to a village from the direct expenditures caused by the greater number of deaths and funeral expenses, arising each year from the unsanitary condition due to the lack of sewers, and from the expenses and loss of time in cases of sickness not resulting in death, and claims that in 20 years' time these amounts, together with the increased fire insurance premiums paid on account of a lack of water supply for fire protection, would pay for the whole cost of both water-works and sewerage, if constructed at the same time, and the sewers and water pipes laid in the same trench.

His statements about the economy to be obtained by using a single trench for both sewers and water pipes, however, would seem to require some modification. The water pipes could not well be placed directly over the sewers on account of the manholes, if for no other reason; nor should they be laid on the filled-in material without its being very thoroughly rammed, as otherwise settlement would cause distortion and leakage, if not absolute rupture of the mains, especially where the contour of the surface of the streets causes considerable and sudden variation in the relative depths of the sewers and water pipes. If a trench be cut entirely on one side of the sewer trench, so as to support the water-pipe on solid ground, as seems to be indicated in Mr. Babcock's paper, it is hard to see how very much saving in earthwork would result—although doubtless there might be some economy in prosecuting both works simultaneously, as suggested.

Though the arguments in the article are forcible and commendable, some of the figures relative to capacity of stand-pipes and mains need revision.

SANITARY DISCUSSION IN TEXAS.

Some funny literature regarding the water supply of Tyler, Tex., was recently given in *The Daily Democrat and Reporter* of that town. One of the articles was in the shape of a report from the City Chemist on the water furnished by the water-works. He found that it contained "total solids, 12.2 grains per gallon, and chlorine, 1.5 grains per gallon," saying nothing about ammonia or albuminoid ammonia, and condemned the water.

This report was criticised by a druggist, who says that he is "perfectly bewildered to know what conclusion the analyzer himself has reached," and that "if our young chemist really wishes to find some water deleterious to health, let him examine some of the water from some of the wells in Tyler, and he will find them rich in albumoids, nitrites and chlorides, which he may search for in vain in the water-works water."

Thereupon the chemist arose in his wrath and said that he made the report as a matter of duty, and "now then, by that action arises an impromptu, presumptuous, small gentleman (at the instigation of the water company we all suppose), in an off-hand essay fires at the report (under a state of bewilderment—think of it), a conglomerated ball of words which have lost their fell purpose, if we closely observe the effects." There is a good deal of "fine writing" in the chemist's reply, of which the above is a sample.

The best comment is an editorial in the same paper—which editorial has no special reference to this controversy, but seems to fit it beautifully. It reads:

"When it comes to settling any very difficult municipal or political question, Tyler takes the confectionery. Friends, brothers, men, women, children, disagree, and yell, and whoop, and tear their shirts (at least the men do), and raise sand, and when at last the thing is settled they all get together in the 'middle of the road' and live happy and quiet until next election, or until another question arises for discussion. It just beats the world to see them rear. They make so much fuss it generally scares an outsider afraid: but the regular Tylerite never pays any attention to it, except to raise his *pro rata* of dust and whoop in chorus with the others. It's funny; but it's only our style, and we can't help it."

TELPHERAGE AT EDINBURGH.

The most recent improvements in telpherage are shown in the telpher line put up at the Edinburgh Exhibition by the Electrical Engineering Corporation, which is arranged so as to carry passengers as well as to demonstrate the advantages of the system for transport of goods. The system provides for the transport of a wide range of material, from minerals and heavy freight to light packages, and an overhead line is employed, with carrier suited for the employment of electricity in the transmission of the power required. The Edinburgh line consists of over a quarter of a mile of track, the flexible portions being constructed in spans of 50 feet and the rigid ends in spans of 15 feet. The ropes on which the locomotives and cars travel are of steel, and 1⅓ inches in diameter. These are tightened, so that with a full load on the line there is a sag of about 2 feet 4½ inches on the spans covered by the train. The working of the line is said to have given great satisfaction.

The principle of the telpherage system was outlined in The Engineering and Building Record of March 15, 1890.

THE PROPOSED EAST RIVER TUNNEL.

The New York Board of Aldermen will be called upon shortly to act finally upon the application for a franchise made several years ago by a company formed to build the underground New York and Long Island Railroad. The company was organized under the General Railroad act of 1850, and its amendments, which require that the consent of a majority of the property owners on the street under which the road is to run, and the assent of the city shall be obtained. The consent of the property owners was obtained a year ago, and all that is required now is the assent of the corporation. The plans of the tunnel were submitted to the Aldermen three years ago, but the matter has been put off from time to time. It is now believed that the work will soon be under way.

Its promoters say that the actual and pressing need of better facilities for the transportation of both passengers and freight across the river is too apparent to require discussion, and that the advantages that would follow the completion of such an underground railway cannot be overestimated. The city is taxed to its utmost already by its peculiar shape, and the surplus population must find living accommodations in either New Jersey or Long Island. This surplus is increasing rapidly. The Brooklyn Bridge provided an outlet for the overflow to a certain extent, but it is no longer equal to the demands made upon it. Neither are the ferries. In fact, the present facilities are entirely insufficient for handling the great increase in population. No provision has hitherto been made for the increased quantity of freight that results from the increase in the population.

The new company saw that to meet the requirements it must introduce a system that would work with the elevated railroads and be so planned as to form a part of any rapid transit system which may be ultimately constructed. Col. Oliver W. Barnes, the chief engineer of the company, had this fact in mind when he prepared the plans.

The proposed tunnel will extend from the Hudson River on the west side of New York, under Forty second Street, in a direct line across the East River to Long Island City. The idea of this is to establish a complete rail connection between the New York Central and Hudson River Railroad and the Long Island Railroad. From Tenth Avenue the tunnel descends on a grade of 68 feet to the mile, passes under the East River, and then ascends to the Long Island Railroad at a point one mile from the river. The average depth of the tunnel below the river bottom is 50 feet. The tunnel will be connected with the elevated roads by elevators. There will be stations at Sixth and Ninth Avenues, on the west side, and at Second and Third Avenues, on the east. The central part of each station will be 100 feet square. Platforms 150 feet long will run from the central parts, making the entire station 400 feet in length. Stairways will be built in addition to the elevator shafts.

A shaft will be sunk at each shore, from which the headings will be driven. These shafts will be 3,300 feet apart. The line across the river passes under Man-of-War rock, which is bare at low water. A coffer-dam, having an area of 3,000 square feet, will be constructed here, and a third shaft will be sunk to the level of the tunnel and connected with it, for the raising of such materials as can conveniently be brought to that point. This plan provides for the working of two additional headings, and also constitutes the first step for the removal of this rock by the Government in operations like those prosecuted at Flood Rock. The tunnel is to be five miles long.

NOTES.

There is some talk, at present, of an international engineering congress, to be held at Chicago during the World's Fair. Nothing definite, however, has yet been determined upon.

Measures have recently been taken by the Mexican Government with the view toward the adoption of the metric system as the only system of weights and measures to be used in the Mexican Republic.

A New Haven, Conn., ordinance, which is strictly enforced and ought to commend itself favorably to all cities, reads: "Be it ordained by the court of Common Council of the city of New Haven: No person shall distribute, throw, drop, or cause to be distributed or dropped, in any of the streets or public squares of said city, any posters, handbills, advertising cards, or other substance used for the purpose of advertising. Every person violating this provision shall pay a penalty of not more than twenty-five dollars for every such offense."

The committee on the celebration of the opening of the St. Clair River Tunnel at Port Huron, Mich., have agreed upon the outlines of a programme. A grand banquet will be held in the tunnel itself. The table is to be 1,000 feet long, and located so as to be 500 feet on each side of the international boundary. The chairman is to be seated exactly on the line. On the Canadian side of him will be the President of the United States, and on the American side the Governor-General of Canada, while Ministers of State and other notables from both countries will be judiciously disposed of. The tunnel will be brilliantly lighted by electricity.

MEETINGS OF ENGINEERING SOCIETIES.

The American Society of Civil Engineers holds its regular meetings on the first and third Wednesday in each month, at the House of the Society, 127 East Twenty-third Street, New York.

The Boston Society of Civil Engineers holds its regular meetings at the American House, Boston, at 7.30 P. M., on the third Wednesday in each month.

The Western Society of Engineers holds its regular meetings at No. 78 La Salle Street, Chicago, at 7.30 P. M., on the first Wednesday in each month.

The Engineers' Club of St. Louis holds regular meetings in the club's room, Laclede Building, corner Fourth and Olive Streets, St. Louis, on the first and third Wednesdays in each month.

The Engineers' Club of Philadelphia holds regular meetings at the House of the Club, 1122 Girard Street, Philadelphia.

The Engineers' Society of Western Pennsylvania holds regular meetings on the third Tuesday in each month, at 7.30 P. M., at its rooms in the Penn Building, Pittsburg, Pa.

The Engineers' Club of Cincinnati holds its regular meetings at 8 P. M. on the third Thursday of each month at the Club rooms, No. 24 West Fourth Street, Cincinnati.

The Civil Engineers' Club of Cleveland holds regular meetings on the second Tuesday of each month, at 8 P. M., in the Case Library Building, Cleveland. Semi-monthly meetings are held on the fourth Tuesday of the month.

The Engineers' Club of Kansas City meets in Room 200, Baird Building, Kansas City, Mo., on the second Monday in each month.

The Engineering Association of the Southwest holds regular meetings on the second Thursday evening of each month at 8 o'clock, at the Association headquarters, Nos. 63 and 64 Baxter Court, Nashville, Tenn.

The Civil Engineers' Society of St. Paul meets at St. Paul, Minn., on the first Monday in each month.

The Montana Society of Civil Engineers meets at Helena Mont., at 7.30 P. M., on the third Saturday in each month.

The Civil Engineers' Association of Kansas holds regular meetings on the first Wednesday in each month at Wichita, Kan.

The New England Water Works Association holds quarterly meetings in Boston at Young's Hotel.

The Canadian Society of Civil Engineers holds its regular meetings on each alternate Thursday, commencing with the 9th of October, at the House of the Society, 112 Mansfield Street, Montreal.

The Engineering Department of the Brooklyn Institute, Brooklyn, holds regular meetings, at 8 P. M., on the third Tuesday of each month. Until the Institute building is repaired, the meetings will be held in the rooms of the Young Men's Christian Association Building, 502 Fulton Street.

An application, now said to be before the Municipal Council of Paris, is for the purpose of securing permission to erect an electric central station in order to utilize the power of a new artesian well situated in the Herbert Place, La Chapelle. La Chapelle is the center of a large industrial population, and it is intended to use several turbines in driving the dynamos, which will supply current for light and power to the surrounding districts.

The regular meeting and dinner of the Architectural League will be held at the "Arena," No. 41 West Thirty-first Street, on Monday evening, November 3, at 6.30 o'clock. Mr. C. H. Blackall, of Boston, will read a paper on Portuguese Architecture.

According to a western paper, the great Bear River canal, in Utah, for the construction of which $2,000,000 has been provided, is expected to be one of the most extensive irrigation works in America.

PERSONAL.

At the annual meeting of the Board of Water Commissioners of Madison, Wis., John B. Heim was elected Superintendent for the ensuing year, and John F. Donovan, Secretary.

M. Henri Rousseau, of Paris, France, an engineer of the Bridge and Highway Department of France, is making a short visit to St. Louis, to inspect for his Government the river improvements that the United States Government is carrying on there. He has a letter from the Chief of Engineers of the United States Army, introducing him everywhere, and asking that everything possible be done to assist him in obtaining any information he may wish. He goes from St. Louis, to the other large cities on the Mississippi and Ohio Rivers.

OBITUARY.

Lotan K. Hunt, who was for many years prominently identified with the building trade of New York City, died on October 16.

A. B. Mullett, Supervising Architect of the Treasury Department during Grant's administration, committed suicide at Washington on the 20th inst.

Dr. John Farnham Boynton, credited with being the inventor of the Babcock fire extinguisher, died at Syracuse, N. Y., on October 20. He was born in 1811.

ENGINEERING SOCIETIES.

A REGULAR meeting of the Civil Engineers' Club of Cleveland, O., was held on Tuesday, October 14. Prof. Charles H. Benjamin and Mr. James W. Gallup were elected active members.

Mr. J. H. Sargent read a paper on "Railroads; Past and Prospective," giving an entertaining account of the development of the modern railroad from the stone tramway, as found in ancient ruins, noting especially the more rapid stages that he had personally observed since he began his professional career, and predicting that in the near future all trains will be moved by electricity.

The reading of the paper was followed by a discussion, in which a number of members described their personal experiences of a few years ago, showing the rapid progress that has taken place within their recollection.

Mr. Robison described a projected electric railroad between New York and Philadelphia, on which it is proposed to dispatch light trains every ten minutes from the terminals, and make the trip in 40 or 50 minutes.

Mr. J. B. Larned gave a description of the Grand Avenue Bridge at St. Louis, which is of the stiffened suspension type, with an upper tension chain of steel eyebars, and a lower chain, parallel to it, but made for compression, and triangular bracing between them.

This was followed by a brief description of the new cantilever bridge over the Ohio River between Cincinnati and Newport, now building.

NEW YORK ARCHITECTURAL LEAGUE COMPETITION.

THE fourth annual competition of the Architectural League of New York for the gold and silver medals of the League, in connection with the sixth annual exhibition, has been announced. The conditions are:

First.—The competitors must be residents of the United States, and under the age of 25. *Second.*—The drawings shall be made in conformity with the appended programme, and in all parts and portions entirely by the hand of the competitor. The drawings will be judged by the jury appointed for that purpose. The successful drawings, and such others as may be thought worthy, will be hung at the exhibition, the first and second prize drawings being so indicated, and these latter shall thereupon become the property of the League.

According to the programme an heroic statue of Zeus, standing 9 feet high, has been secured by an American citizen from one of the excavations now going on among the ruins of Greece, and presented to one of our large cities. The municipal government, appreciating the value of the gift, proposes erecting a loggia for its reception and protection. This pavilion is to be located upon a plot of ground formed by the conjunction of two avenues with a boulevard, the form and size of which are given. The structure should be of marble, and must be classic in treatment. Each contributor is required to exhibit two sheets of drawings: one to contain the front elevation, drawn to a scale of ¼ of an inch to the foot, and rendered at will; and the other to contain the ground plan, section, and such other drawings as may be necessary to explain the design and construction, and drawn to the most convenient scale for the purpose, and rendered at will. A small perspective sketch, rendered fully at will and taken from a designated point, can be shown upon either of the two sheets. Each sheet to be cut to the uniform size of 24x32 inches, and to be white card or Bristol board, or Whatman paper mounted on stretcher. No colored borders, frames or glazing will be allowed. Each sheet must be distinguished by a motto or cipher. A sealed envelope, bearing the same motto or cipher, must contain the name, full address, place and date of birth of the author, and must be mailed to the Medal Committee.

VIADUCT IN SPAIN.

EXCAVATORS OPERATED BY ELECTRIC MOTORS.

AN excavator operated by electric motors is now in use by the Bennett Amalgamator Company, of Denver, in connection with one of their amalgamators, working in gold-bearing gravel beds. There are two motors, one of 25 and one of 15 horse-power. In addition to these another 25 horse-power motor is mounted on the car and is employed in driving the conveyor and the amalgamator. The electric current is furnished by a 100 horse-power dynamo driven by water-power and located at a distance of about one and one-half miles from the mines where the shov [illegible] operation. The excavator was built by the [illegible] Company, of Albany, N. Y.

THE MAINTENANCE AND OPERATION OF WATER-WORKS BY PRIVATE COMPANIES.

(Continued from page 269.)

51. *Dividends.*—Charge this account, and credit "cash" with all sums paid as dividends on the capital stock of the company.

52. *Profit and Loss.*—At the end of each year, when the books are closed, carry the balances of the following accounts on to the opposite side of "profit and loss," and balance "profit and loss" account into "balance" account.

No. of Acct.	Name of Acct.	No. of Acct.	Name of Acct.
6	Public Hydrant Rental Accounts Receivable.	31	Boilers.
7	Private Hydrant Rental Accounts Receivable.	32	Pumps.
8	Water Accounts Receivable.	33	Fuel.
10	Services and Repairs Accounts Receivable and Payceivable.	34	Oil and Waste.
11	Miscellaneous Accounts Receivable.	35	Lighting.
19	Organization.	36	Stand-Pipe.
21	Real Estate.	37	Distributing Reservoir.
22	Water Supply.	39	Salaries.
23	Improvement of Water.	40	Legal Expenses.
24	Storage.	41	Superintendent.
25	Water Power	42	Engineering.
26	Conduits, etc.	43	Engine Men.
27	Distribution.	44	Office Expense.
28	Buildings.	45	Livery.
29	Foundations.	46	Interest.
30	Water Wheels.	47	Discount and Commission.
		48	Taxes.
		49	Insurance.
		50	General Expense.
		51	Dividends.

53. *Balance.*—At the end of each year, when the books are closed, carry the balances of the following accounts on to the opposite side of "balance."

When the books are opened for the next year, carry the amounts from this account on to the opposite sides of the new accounts.

No. of Acct.	Name of Acct.	No. of Acct.	Name of Acct.
1	Capital Stock.	15	Meter Rents.
2	Bonds.	16	Service and Repairs.
3	Bills Payable.	17	Miscellaneous Accounts.
4	Cash.	18	Bills Receivable.
5	Treasurer.	20	Construction.
12	Public Hydrant Rental	38	Meters.
13	Private Hydrant Rental.	52	Profit and Loss.
14	Water Rates.		

Whenever "Trial Balances" are made, the sum of the balances of the following accounts will show the earnings of the company for the current year to date:

No. of Acct.	Name of Acct.	No. of Acct.	Name of Acct,
6	Public Hydrant Rental Accounts Receivable.	10	Services and Repairs Accounts Receivable and Payable.
7	Private Hydrant Rental Accounts Receivable.	11	Miscellaneous Accounts Receivable.
8	Water Accounts Receivable.		
9	Meter Rents Accounts Receivable.		

While the sum of the balances of the following accounts will show the amount of uncollected earnings to date:

No. of Acct.	Name of Acct.	No. of Acct.	Name of Acct.
12	Public Hydrant Rental.	15	Meter Rents.
13	Private Hydrant Rental.	16	Services and Repairs.
14	Water Rates.	17	Miscellaneous Accounts.

BLANK BOOKS AND BOOKS OF RECORD.

Those regularly used are as follows:

No.	NAME.	Distinguishing Tint.	Record No.
1	Power of Attorney to sign Application	White.	906
2	Tap Order.	"	907
3	Service Pipe Order.	"	908
4	Plumbers' License	"	009
5	Plumber's Bond	"	910
6	Meter Order.	Primrose.	911
7	Inspection and Turn-on Order	Opaline.	912
8	Shut-off Order	Pink.	913
9	Shut-off Book	....	938
10	Repair Notice	Blue.	914
11	Record Book	... ...	934
12	Meter Book	.. ....	939
13	Meter Reading Book	....	935
14	Inspection Book	....	936
15	Complaint Book	....	937
16	Order Book	....	918
17	Bills, Fixture Rates	White.	915
18	Bills, Meter Rates	Primrose	916
19	Bills, Miscellaneous	Opaline.	917
20	Gate Book	... .	921
21	Hydrant Book	....	922
22	Street Plan Book	....	923
23	Maps	....	. .
24	Vouchers or Bill Covers	Lilac.	905
25	Trial Balance Sheets	Colors vary according to the company.	940-945, etc.

Lilac is "linen bond," made by Hampshire Paper Company. Other colors are "wove," made by Carew Company, weighing 24 pounds per ream, 17x22.

1. POWER OF ATTORNEY TO SIGN APPLICATION BOOK. Color, white. Record No. 906.

This form is to be used in cases mentioned in the general description of the Application Book. In too many cases in the past the Application Book has been signed by almost anybody, or not at all.

Every customer, every separate service connection, and every separate connection for private fire protection, must have a separate application. Whenever the owner cannot make application in person he must fill out, sign and send to the office one of these powers of attorney, authorizing some person to sign for him; or he may sign it, leaving the name of the attorney blank, send it to the office and the superintendent, or some one in the office may fill in their name, and then sign the application book.

These powers of attorney must then have the name of the applicant, the number of the application, and the stop number filled in on the back, and be filed away according to the application number.

2. TAP ORDER. Color, white. Record No. 907.

When an application is on the books and the tap ready to be made, fill out the Tap Order blank, giving the details called for by the blank spaces.

The foreman of the service department will then make the tap and return the blank to the office, properly signed and dated and with the tap number filled in. This tap number is always a consecutive one, and is kept by the foreman of this department, but is not a record number on any office book. On the diagram on the back of the blank should be filled out such dimensions and measurements as are necessary to locate the tap, and this should then be transferred by the office to the Record Book.

After the records are all transferred from this blank to the proper books, it should be filed away according to the application number.

3. SERVICE PIPE ORDER. Color, white. Record No. 908.

If arrangements have been made with the owner by which the company is to put in the service pipe and fittings from the main to the property line, or to and into the premises, this blank should be filled out and given to the foreman of the service department when the Tap Order is given him. If the company are only to put in the service pipe to the property line, then a duplicate should be filled out and given to the licensed plumber, who is to do the rest of the work. But, if a licensed plumber is to do all the work from the tap, then only one Service Pipe Order form is filled out, and that given to him.

Each form should have the application number filled out before it leaves the office, but the stop number is not given to it until after it is returned. The party doing the work must fill in the blanks on the face of the permit, giving the sizes and kinds of pipe and fixtures put in, and on the back make and fill out a diagram of the same.

When returned to the office, this information will be transferred to the Rate and Record Books, and this form filed away according to the stop number.

When any party desires additions to or changes made in their connections or fixtures, the party making such changes must obtain a permit from the office and fill out and return the same, giving the sizes, number, and location of all fixtures then in use, the same as though it was all new work. The necessary changes, additions, or corrections must then be made in the rate and record books, the permit numbered the same as, and filed away with, the original permit of the same stop number.

In case the company do a part of the work, and a licensed plumber the remainder, then both permits will bear the same stop number, and they will both be filed together.

4. PLUMBER'S LICENSE. Color, white. Record No. 910.

All plumbers who desire to do any service pipe or plumbing work in connection with the works of the company must have a license, duly signed and numbered; and all licenses will expire on the 1st of January in each year.

This gives the company opportunity to refuse to relicense any plumber who may not have done satisfactory work during the previous year.

When a license is renewed, it will bear the next consecutive number to the last one issued.

The superintendent cannot refuse a first license to any plumber without strong reasons, but can revoke one at any time, by written notice, if facts and circumstances warrant the same.

When a license has once been revoked, another may be issued to the same party if the superintendent thinks it best to do so.

A record of all licenses should be kept in some convenient book.

5. PLUMBER'S BOND. Color, white. Record No. 910.

Before any license is issued, the plumber must furnish a bond in the sum of $1,000, with two satisfactory sureties to idemnify the company and the customers for any loss or damage which may arise by reason of the negligence, carelessness, or incompetency of the plumber, all as stated in the bond.

When a bond is once given, accepted, and the license issued, no other bond need be given unless it is revoked by the sureties, which revocation is of no avail if action has been commenced under the bond; but, if no action has been commenced, then the revocation of the bond will warrant a revocation of the license until such time as a new bond is furnished.

In case of any loss or damage arising from the carelessness, negligence, or incompetency of the plumber, make out a full detailed statement of the same, and ask the plumber for immediate settlement. If he refuses, then place the matter in the hands of the company's attorney for action.

6. METER ORDER. Color, primrose. Record No. 911.

Whenever a meter is required on any surface, fill out the Meter Order blank, and give it to the foreman of the service department. No one but an authorized employee of the company must ever set a meter.

When the meter is set, the order must be returned to the office by the foreman, after first filling out such blanks as may be necessary, dating and signing the same. These orders will then be filed away according to the stop numbers.

7. INSPECTION AND "TURN-ON" ORDER. Color, opaline. Record No. 912.

When the Service Pipe Order is returned, the Inspection and Turn-on Order is filled out and handed to the inspector. He at once proceeds to inspect the premises; and if he finds the connections and fixtures satisfactory, and conforming to the rules and regulations in relation thereto, and agreeing with the plumber's return, he turns on the water, fills the pipes, reads the meter, if there is one, fills out his blank, dates it, signs it, and returns it to the office. If the connections or fixtures are not satisfactory, he so indicates on his report, returns the same, and makes written report to the office as to wherein they are unsatisfactory.

The office then notifies the owner and party who did the work, which must be made right before the water is turned on.

If more than the first inspection is required on account of poor, or otherwise unsatisfactory, work having been done by any licensed plumber, such plumber must pay the sum of $2 to the company for each inspection after the first, or, if he refuses, his license may be revoked.

When a plumber has been putting in any connections or fixtures or making any repairs or alterations on the same, he may turn on or off the water, at the sidewalk stop only, but he must always leave the stop in the same position he found it, whether "on" or "off," or be subject to a fine, to be paid the company, of $2 for each case or to have his license revoked, or both.

If water has been turned off for "penalty" or "vacancy" where there is no meter, it may be turned on again by any employee of the company under verbal orders from and reported to the office; but, if there is a meter, it must be done and reported by the Inspector.

Any person turning on or shutting off water except as indicated above will render himself subject to punishment or fine, or both, as may be provided for by Ordinances, or by Rules and Regulations.

After the Inspection Order is returned to the office, the necessary transfers will be made from it to the Rate Book and other books, and then be filed according to the stop number.

(TO BE CONTINUED.)

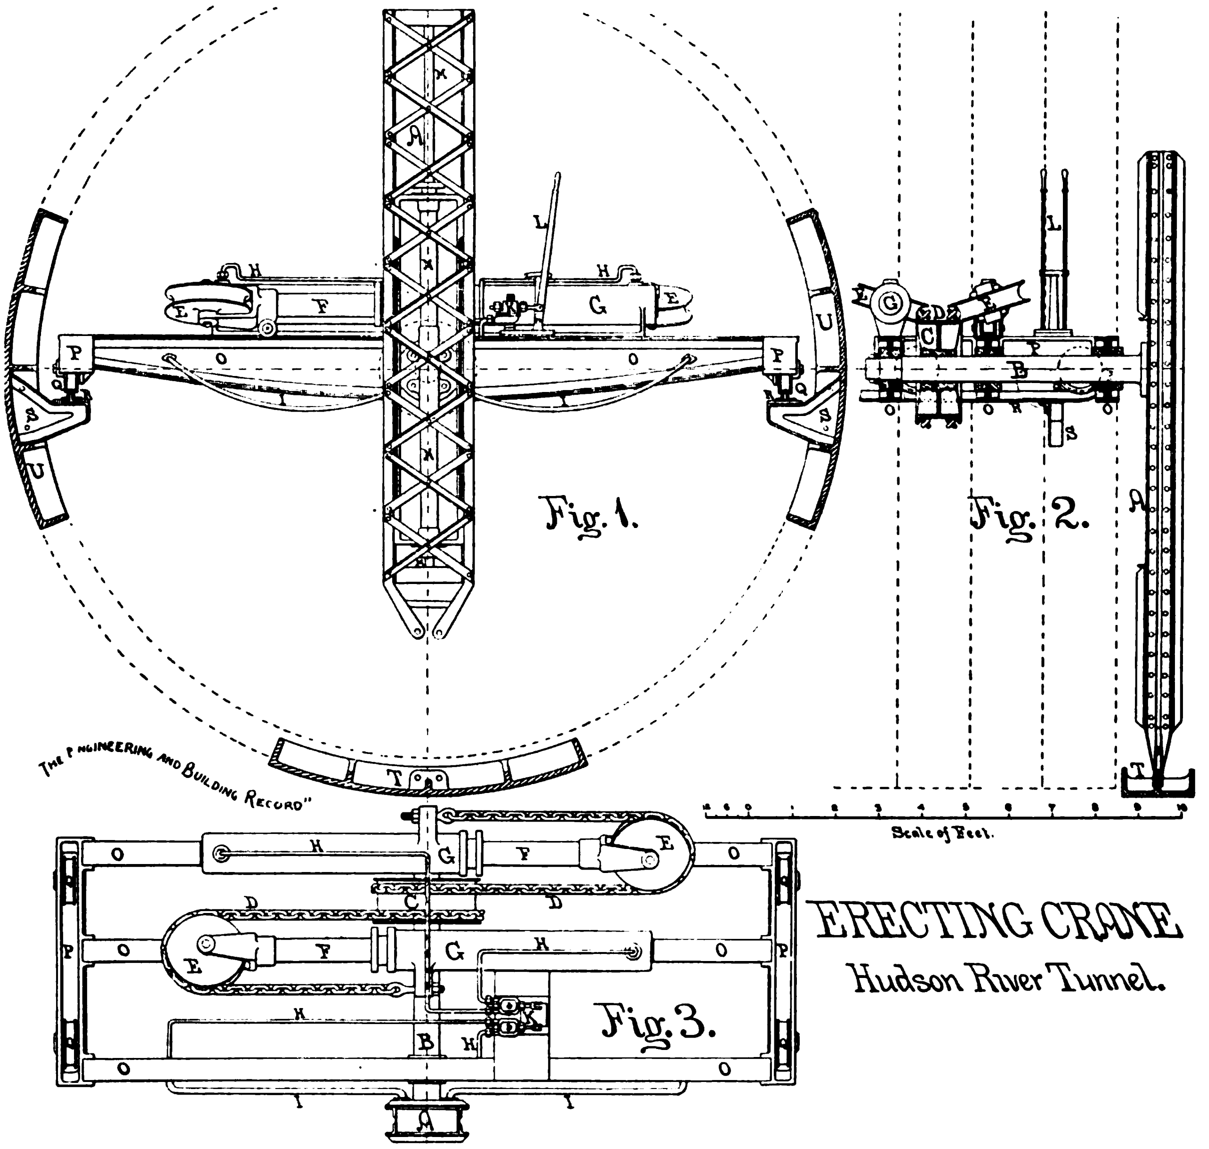
FIFTY feet of the dam at the dry dock in course of construction at Kingston, Ont., gave way recently, and the great excavation is now full of water. A new dam will have to be built, and the dock, it is said, cannot be pumped out before the spring. The loss is reported to be $10,000.

ERECTING CRANE USED IN THE HUDSON RIVER TUNNEL.

IN describing, on page 291 of Volume XXI., the recent fire at the New York end of the Hudson River Tunnel, mention was made of the proposed change in the plan of construction, whereby cast-iron plates were to be substituted for the brick lining which had so far been used, a method substantially the same as that adopted in the St. Clair Tunnel, described on page 227 of the same volume.

This plan has now been carried into effect, and the cast-iron cylinder is being built out from the New Jersey side at the rate of about one ring, some 20 inches in width, a day; a rate that will be much increased when certain improvements are made and the men become more familiar with this new mode of working.

The most striking feature of this method of construction is the erecting crane shown in the accompanying illustrations, by which the cast-iron plates, weighing 1,000 pounds each, are placed in position without manual labor. This apparatus was designed under the direction of E. W. Moir, who, as engineer for the contractors, S. Pearson & Son, of London, has immediate charge of the work.



ERECTING CRANE
Hudson River Tunnel.

Its construction and operation are as follows: A horizontal shaft or spindle B, whose axis is concentric with that of the tunnel, carries on its forward end a casting on which slides the arm A whose motion is controlled by the lifting rams M M working in cylinders N N, Fig. 1 The shaft B is supported by three bearings in as many transverse wrought iron girders O O O whose ends rest on cast iron frames P P. These in turn are carried by wheels Q Q, etc., running on rails R R supported by brackets S S bolted to some of the side plates U U of the cast iron rings, which are indicated by the dotted lines in Figs. 1 and 2.

On shaft B is keyed a drum C on which are wound in opposite directions the chains D D, and by which when actuated by the slewing rams F F carrying sheaves E E and working in cylinders G G, the shaft B may be rotated something more than a half circle in either direction.

The movement of these rams is controlled by water under a pressure of 1,000 pounds per square inch, which is admitted to them by valves at K operated by two levers L L, one for the lift and the other for the slewing rams. The water is conveyed to the slewing rams by ⅝-inch brass pipes H H and part way to the lifting rams by the same means, but in order to permit the rotation of the lifting arm, 1¼-inch rubber hose I I wrapped with steel wire is used for the rest of the way. The force and waste pipes which convey the water to and from the crane are not shown, and for convenience all pipes have been omitted from Fig. 2, and the working chains are not shown in Fig. 1.

In Fig. 1 arm A is shown with its working end down and run in or lifted to its highest point. Immediately under it is a plate T ready to be put in place. To do this arm A will be lowered until the bolt holes at its lower end coincide with those in the casting T as shown in Fig. 2. The two will then be bolted together, arm A will be raised so that the plate on its end will clear the plates already in position and revolved until plate T is opposite its proper place when arm A will be again extended and the plate finally put where it belongs. When the plate has been secured arm A will be unbolted and withdrawn ready to repeat the series of operations.

The rams have been so proportioned that though of ample power to perform their legitimate work the crane cannot be used to force ill-fitting plates into position with the risk of straining or breaking the crane or of displacing work already in place.

Although the crane has only been in use a very short time its performance is said to be very satisfactory, and it will doubtless very materially expedite the progress of the work in the tunnel.

Official information recently received at Washington, is said to furnish ground for confidence that the Nicaragua Canal will be completed within the next six or seven years. There are now more than 1,000 men at work on the line and six surveying parties are in the field under the direction of Chief-Engineer Menocal, making details and estimates upon which to base contracts with private corporations for the necessary dams, locks and excavations.

ACCORDING to a Deadwood, S. D., report the tunnel of the Fremont, Elkhorn and Missouri Valley, 2,079 feet in length, including approaches, was practically opened on the 10th inst.

IMPROVING THE MISSISSIPPI'S CHANNEL.

THE importance centered in Mississippi River improvements lends special interest to the following account published in *Harpers' Weekly* a short time ago :

"There are three theories for the improvement of the Mississippi, as widely different as any three could be. The one which has been adopted is that the water should be restricted within certain boundaries in the course of its flow, so that by its own force and velocity it shall keep its own bed scoured out, and maintain a navigable depth throughout its course. There are few great rivers swifter in running than the Mississippi, and it is urged that if its course be properly directed, so that it shall not spread out into lakes, and so lose its rapidity for a distance, the water will not only carry off the sediment with which it is charged when it reaches the valley, but will carry with it some portion also of the soft mud of the bottom already deposited there by the water that has passed before.

"Practically, it is doubtful whether this theory has entirely vindicated itself. Captain Eads did, it is true, establish a channel from New Orleans to the sea, and he had adopted this theory, but the water did not perform the work expected of it. A great stream was flowing through the South pass, and it was thought that if this stream should be made narrower, it would, by its own force, become deeper, so the jetties were built. The primary result was the exact opposite to what had been expected. The water, finding its old path narrowed, followed its confirmed habit of seeking the line of least resistance, and in a short time it was found that the obstructions in the South pass were actually improving the channel in the Southwest pass. This might have been considered a partial demonstration of the correctness of the theory, unexpected as it was in the way of a result, but it was by no means gratifying to Captain Eads. Several million dollars remained contingent upon the improvement of the South pass, and he treated the wayward river with both coercion and coaxing. He put a submerged dam across the neck of the Southwest pass, that the water should not thus get away from him, and he got the most powerful dredging machines ever built, and began clearing out the mud of the South pass, which the water would not carry away for him. This dredging was continued for some years, until the channel was really established. The dredging has now been discontinued for some time, and the channel seems to be maintaining itself.

"It is claimed, however, by the believers in the second theory that this appearance is deceptive. The outlet theory, as it is called, has many strenuous advocates, who urge that the only thing to be done with safety to the Mississippi River is to remove obstructions, and to provide new outlets here and there through which the surplus waters of the periodical floods shall find their way easily to the ocean. They argue that anything in the way of an obstruction tends to retard the flow of the water; that even a narrowing of the river bed at any given point is practically an obstruction, and instead of increasing the scour, really increases the amount of deposit made by the water as it flows, and so tends to choke the river up instead of keeping the channel clear. It is certain that the water of the lower Mississippi is almost a saturated solution of mud and that if the water is really retarded, its inevitable tendency is to drop its sediment. These theorists ridicule the alleged success of Captain Eads' work, and declare that the real result of it has been to raise the bed of the river above it. This assertion was boldly made in the recent discussion of the River and Harbor Bill in Congress, but it does not appear to be supported by any actual demonstration of the fact, if it be a fact. The conclusion reached by this school of thinkers is that the entire plan of work of the Mississippi River Commission is radically wrong, and the only result to be looked for from their labors is serious mischief.

"The third theory has never been strenuously urged, though it has the sanction of ancient usage in China. It has been conceived possible to hold back the waters which in wet seasons make the floods, and by confining them in great basins or reservoirs to regulate the flow from season to season, rendering droughts and floods, extreme high water and extreme low water in the channel alike impossible. Theoretically speaking, this can be done, and it is even pointed out that nature has provided just such a reservoir in one place at least, where, with the aid of comparatively little artificial construction, it would be possible to confine an enormous volume of water for an indefinite period. This is in the St. Francis basin or valley, often called the Sunken Land of Arkansas. Here, in consequence of earthquakes that occurred early in the present century, the surface of the ground was lowered—it is said more than 10 feet. Very probably this is an excessive estimate, for no accurate surveys were recorded. At all events the basin is there, abounding in lakes and streams, which find their outlet through the St. Francis River into the Mississippi, and there nature herself practices in a wild way this very reservoir theory whenever the floods are remarkably high ; for the waters at the juncture of the Ohio and the Mississippi not infrequently break away to the westward and flood the entire sunken district."

A MOVEMENT is on foot in New York City to have the Forty-second Street Reservoir removed. It is claimed to answer its purpose as a storage reservoir only inadequately and to be a menace to health, owing to its leaky condition and the consequent dampness of houses in the adjoining streets.

BUILDERS' AND CONTRACTORS' ENGINEERING AND PLANT.

(Continued from page 278.)

ERECTION OF THE HOOGHLY JUBILEE BRIDGE, INDIA.*

PART II.—ERECTION OF THE SUPERSTRUCTURE.†

The superstructure of the bridge is divided into three sections, as shown by Fig. 7, spanned by girders of the triangular type, with curved top booms and straight bottom booms of the ordinary box or trough section. The vertical struts are composed of four angle bars, back to back, and inclined ties of double flat bars, both stiffened by cross bracing. The roadway for the double line of railway is carried between the main girders on four longitudinal plate beams or girders, supported by cross girders, riveted to the bottom booms of the main girders at intervals of 30 feet, which is the length of the panels or bays of the main girders. The girders are strengthened by horizontal diagonal bracing at roadway. The whole of the cantilever and the ends of the side spans have deck-plated roadway platforms and overhead transverse diagonal bracing.

Figure 7 is a general elevation of the bridge, with one side span S in transit. The central, or cantilever, span was erected from the timber false work (two pairs of trusses) on the piers that are shown in solid black, and whose principal pieces were strengthened by double-headed rails partially let into the sides of the timbers, Fig. 6, which also covered the butt joints of the timbers. The cantilever material was sent out from England partially riveted. The total invoice weight of materials in the cantilevers is 1,465 tons. The several sections, in which the materials were sent from England, were floated from the shore on the iron punts and raised by derricks into position and temporarily connected by drifts and service-bolts until the work was sufficiently advanced for riveting. At the points of support on the river piers, inclined struts *o o*, Fig. 5, page 277, fixed at the base to the top of the steel standards, and riveted at the apex to the main uprights of the girders, are provided to resist the pressure of the wind in cyclones. The derricks used were Oregon spars 70 to 90 feet in length; they were guyed from buoys moored in the river and from the pontoons, which were moored on the down-stream side of the river piers, and formed a convenient working platform. The derricks were shifted from place to place on the cantilever platform as required.

Erection of the Main Side Spans.—In the meantime the erection of the girders of the main side spans was in progress. These girders are 420 feet each in length, 30 feet 8 inches apart from center to center, and 47 feet deep over all in the middle. The invoice weight of each span was 1,000 tons. The outer, or cantilever, end of the girders was formed with a step or rebate which rests on a corresponding bench at the ends of the cantilever girders. The inner or shore ends of the girders of the main side spans terminate in castings, A., Fig. 8, bolted to the sides of the end vertical plates with semicircular bearings, which rest upon steel pins B, passing through holes at the bottom of a pair of pendulum links C, suspended on corresponding pins D, carried in holes at the apex of triangular saddle castings E, 9 feet 2 inches high. These castings rest upon and are bolted to cast-iron bed-plates F, 10 feet long by 5 feet wide by 1 foot 10 inches deep, bedded in Portland cement on the brickwork of the abutment, to which they are anchor-bolted. This arrangement provides for the free expansion and contraction of the girders of the side spans and cantilever, from the center of the river pier to the end bearing on the abutment, a length of 540 feet.

The nature of the river bed, the great strength of the floods and tides, and the crowded navigation, made it impossible to provide a fixed staging for the erection of the girders of the main side spans, and they were therefore built on the approach viaducts. On the launching ways, shown in section in Fig. 10, the rails were secured to the timber by coach-screws, the joints of the rails were fished and were further supported by a 5-inch by 5-inch by ⅝-inch plate, let in flush with the surface of transverse pine planks. At the abutment the rails were laid on the cast-iron bed-plate direct, and prolonged to project 3 feet beyond the face of the abutment to carry forward the ends of the launching trollies when the rear ends of the girders reached the center of the abutment. The launching railway on the Hooghly side was level for a distance of 240 feet from the center of the bed-plates; thence it was laid with an incline of 1 in 120 (falling towards the abutment) for a length of 90 feet, beyond which to the rear end of the girders it was level. On the Naihati side the incline was longer but not so steep. The camber blocks on which the main girders were put together were laid on the rails of the launching ways. The whole of the material was raised from the ground and put in place by derricks.

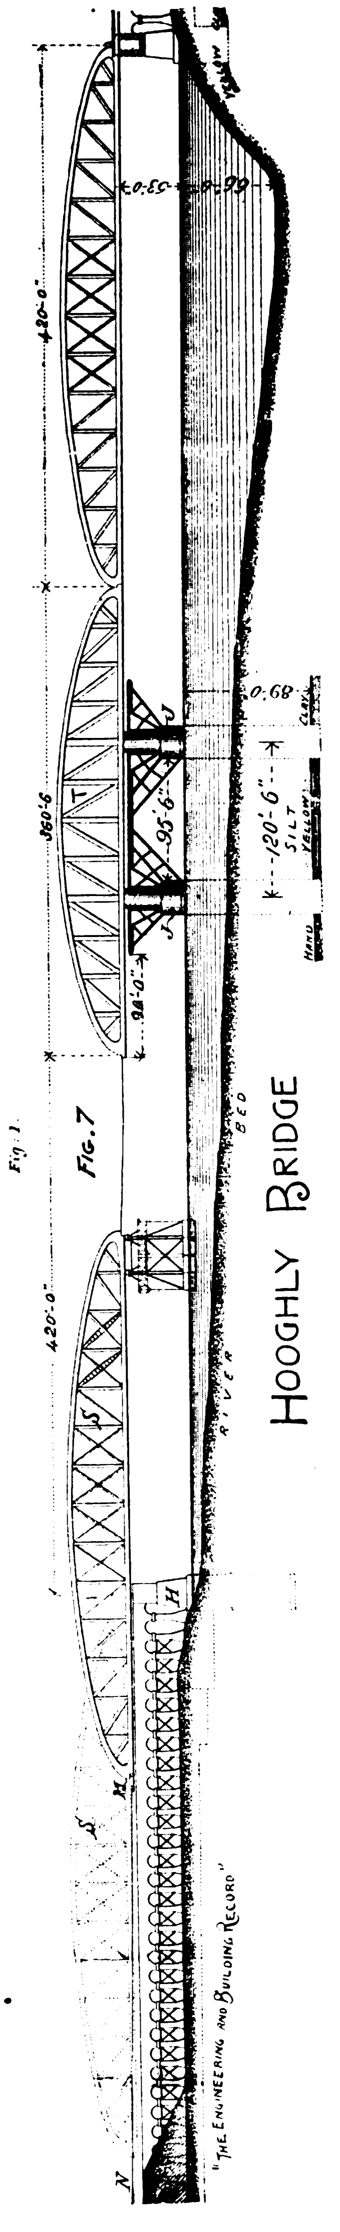

FIG. 7

As erected, the forward or outer end of the girders was 15 feet behind the center of the cast-iron bed-plate, which is 9 feet from the face of the abutment, and consequently the girders had to be pushed out or protruded 75 feet in order that the outer ends might overhang the face of the abutment sufficiently (51 feet) for the pontoons to be berthed beneath for floating them out. For this purpose it was necessary to support the forward ends of the girders at point J, Fig. 9, on a roller platform. In the overhanging portion of the girder, J to H, the inclined tension bars had to be stiffened to prevent them from buckling under the compressive strain to which they were temporarily subjected. The total weight to be carried during protrusion and until launching at point J was about 612 tons, and it became necessary temporarily to strengthen the girders by counter struts J E and K D which were made of old rails and secured to special castings bolted to the gusset plates at J, K, E and D. The struts were formed spindle-shaped. Each pair of rails was connected by ⅞-inch cross bolts at intervals of 4 feet, so that the ends of the struts having been firmly bolted to the cast-iron abutments, they could be expanded to take their share of the weight simply by tightening the cross bolts. To prevent buckling inwards, wooden cross struts, cut to fit, were inserted at each connecting bolt after the latter had been tightened; and, to preserve them truly in line, they were guyed by chains and stretching screws to the top and bottom booms and vertical struts of the main girders. The struts at J E consisted of six pairs of rails; At K D four pairs of rails only were required.

Roller Bearing.—During protrusion, the main girders were supported at point J on a bearing, or sledge, of hard wood cross timbers the full width of the bottom plates of the girders, and extending 5 feet on each side of point J. The bottom box of each girder was stiffened by the insertion of an additional transverse diaphragm 4 feet on either side of J. The underside of the cross timbers, which were dressed to a plane surface and connected together by bar irons let into the ends, rested upon seven parallel, inverted, flat-footed rails 10 feet long, with ends slightly rounded to facilitate the entry of the turned bar-iron rollers, 3¼ inches in diameter, on which the forward ends of the main girders were carried during protrusion. The inverted rails were secured to the hard wood bearing by coach screws. From point J in the original position of the main girders to the ends of the launching ways there were six rails under each main girder to give bearing surface for the bar-iron rollers, which were spaced 8 inches apart.

The weight at the inner or rear end of the main girders during protrusion was 438 tons, and during launching, when their outer ends were supported on the pontoons, 500 tons. It was originally intended to carry the rear ends of the girders during launching on the pendulum links, resting horizontally on 3-foot wheels revolving on the 15-inch pins, and central holes were made in these links accordingly. This would have brought a weight of 270 tons on each side of the viaduct on a wheel-base of 7 feet only. Some doubts arose as to the sufficiency of the foundations to sustain such a concentrated load, and it was thought advisable to provide special trollies to distribute the load over 22 feet of the launching railway. These trollies are shown by Figs. 10, 11 and 12, and were constructed at the works of plate and bar iron. They were inserted between the side plates of the end boxes of the main girders after the temporary removal of a portion of the end bottom plate of the main girders, and of two transverse stiffeners or diaphragms. The end of the main girder was supported on the trolly by the pins B, which were inserted through holes at the center of the main side beams I I of the trolly; these beams were supported on two 7-inch pins G G, passing through holes at the centers of two pairs of smaller inner beams H H, etc., which were carried by the 5-inch axles J J, etc., of four solid cast-iron wheels K K, etc. The bearing of the axles J J, etc., was 4¾ inches broad, and special provision was made for lubrication during protrusion and launching. The side plates of all the trolly beams were double, with solid forged bushes or rings riveted between them at all pin-holes. The top and bottom members of these beams consisted of 5-inch flat-iron bars on edge riveted between the side plates. It will be seen that by this arrangement an equal share of the weight was, under all circumstances, transmitted to each of the eight cast-iron wheels, and the total weight of the girder ends was equally distributed over 22 feet of viaduct instead of over 7 feet only, as would have been the case had the pendulum links been used as originally intended. The two trollies as constructed weighed, with the cast-iron wheels complete, 38 tons the pair.

---

* Condensed from a paper by Sir Bradford Leslie, K. C. I. E., M. Inst. C. E., published in the Excerpt Minutes of Proceedings of the Institution of Civil Engineers, Vol. xcii.

† Part I.—Piers, Caissons, Abutments and Viaduct, was published October 4, 1890.

The trollies having been inserted at the rear ends, the main girders were lifted at the outer end for removal of the camber blocks, and for transferring their weight to the roller bearing at point J. This was effected by hydraulic jacks operating under the step or rebate at the outer ends of the girders. The girders, then supported only on the trollies at the rear and the roller bearings, were ready to be protruded.

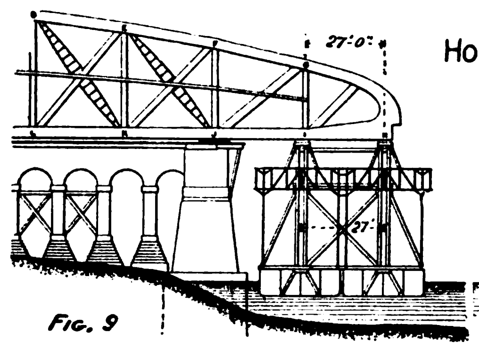

FIG. 9

HOOGHLY BRIDGE

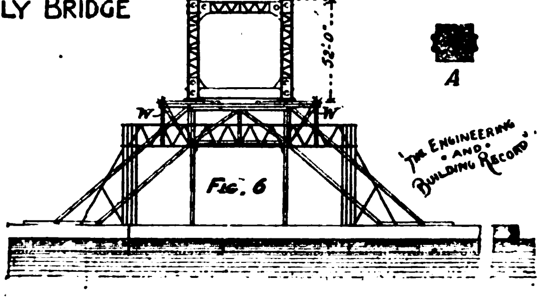

FIG. 6

HOOGHLY BRIDGE

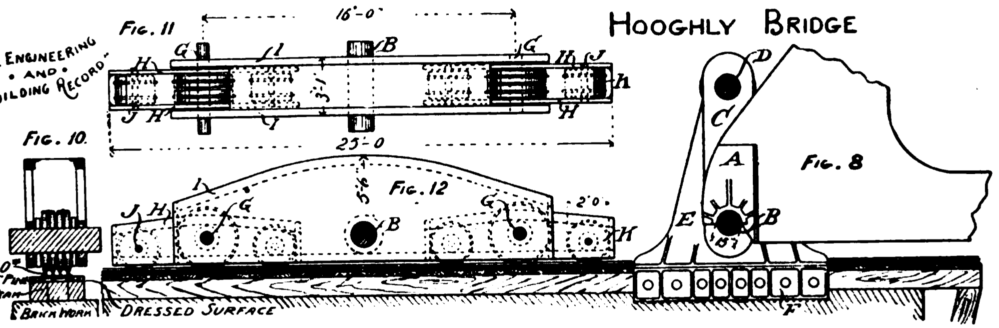

FIG. 11 FIG. 10 FIG. 8

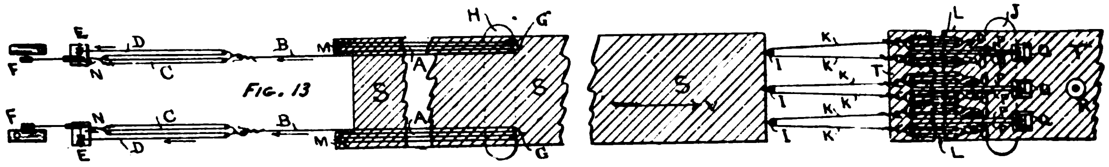

FIG. 13

The tackle for protruding and launching the span is shown in Fig. 13, which a diagram, not to scale and for clearness, shows the pulleys horizontal and somewhat separated, instead of in blocks and in vertical planes, as was the case.

Two sets of 1-inch chain tackles A A (see also Fig. 7), were each made fast to the pier H, at G, and to the rear of span S at M. Their fall lines B, were led to one end of the 4½-inch manilla rope tackles C, the other end of which was made fast at N, and its fall line D, led to the spool of hoisting engine E, driven by a rope from steam engine F. At the forward end of span S three 28-inch sheaves I I I, were attached to the cross beam, and single 4-inch steel wire ropes K K, etc., were rove around them, and each had each end attached to one end of a 6-inch manilla rope tackle L, whose other end was made fast at O to the pier J, and whose tall line P, was led to the spool of a hoisting engine Q, supplied with steam from 20 horse-power boiler R on the floor of the cantilever span T. The operation of all these tackles in the direction indicated by the small arrows, propelled span S in direction V, and it was found that the luff tackles A and C alone were almost adequate for that duty, although increased power had been contemplated in making fast, if necessary, one end of each rope K, and hauling on the other with two of the tackles L.

The protrusion of the girders 75 feet, to position for the final operation of launching or floating was a slow operation owing to the care necessary to keep the 3¾-inch bar-iron rollers square, in other respects no difficulty was experienced.

For floating the forward ends of the main girders and depositing them in position on the recessed benches at the ends of the cantilevers, the pontoons provided for sinking the caissons were used. The central platform, the overhead girders of the rail staging, and the overhanging and central portions of the main trusses, as also the central portions of the auxiliary trusses, were removed, and the pontoons were brought together, as shown in Fig. 9. In this position the pontoons were firmly and rigidly connected together by the main trusses of the rail staging and auxiliary trusses. To carry the girders, a combined timber and rail staging was erected over the central longitudinal bulkhead of each pontoon. Each pair of uprights and rakers was stiffened by old double-headed rails partially let into the outsides of the timbers, Fig. 5, page 277, and each pair of timbers was connected by distance-pieces and through-bolts. Simple butt-joints were used, the rails imparting the necessary stiffness. The entire structure was firmly bolted and clamped together, and secured to the pontoon decks by bolts and strap bolts. Advantage was taken of the rail staging originally provided for the erection and sinking of the caissons, and by which the pontoons were connected transversely, to distribute a portion of the weight to the sides of the pontoons on which the upright supports of the main trusses of this staging were carried (Figs. 9 and 13). This was effected by means of the projecting ends of the top sills of the timber staging, transferring the weight by struts and chains to the overhead girders of the rail staging, the ends of the top sills of the timber staging being trussed by four 5-inch by 1-inch bar-irons W W passing under the lower cross-connecting timbers, and tightly strained by powerful iron wedges.

The height of the special staging for carrying the ends of the girders was regulated by the tides, the object being to secure the longest time available on a single tide for launching the girders, and for the Hooghly span was made 48 feet 9 inches above water level at the light draught, leaving a vertical space of 7 inches to be made good by movable packings. The girders of the Naihati span required a greater thickness of movable packings on the pontoon staging. At points H and I, where the girders were supported by the staging, the rivet heads are not countersunk, and hard-wood packings were fitted to the underside of the main girders to cover the rivet heads at these points. The packing at H was made thicker than that at I, so that the outer pontoon began to take the weight before the inner pontoon, the object being that at high water, when the forward ends of the main girders were considerably higher than the rear ends, the load on the inner pontoon should not be excessive. The draught of water of the pontoons with staging, etc., complete, was 2½ feet. To secure the depth of 1½ feet below datum it was necessary to float the pontoons close to the abutments at the lowest tides that might occur on the dates fixed for launching, and the river-bed was deepened by dredging near the abutments. The additional immersion of the pontoons caused by the weight on the forward ends of the main girders was 2 feet, making the total draught of water 4 feet 6 inches. To keep the forward ends of the girders in line during launching, three barges were moored about 200 yards above the bridge, and three the same distance below the bridge. The line of girders was adjusted by warps from these barges, which were taken to pontoon capstans, and hauled in or slackened as required. The warps were double, passing through sheaves fixed to barges, and the standing part was made fast to the pontoon bollards. The object of this was to insure sufficient strength in case, as was possible, a breeze from north or south might be blowing on the date of launching, which would tend to cause the girders to oscillate laterally and strain the rear launching trollies. The girders of the main side spans were successfully placed in position, with their forward ends resting on cantilevers, one of them in one and a half and the other in two hours, after which about six hours was in each case required for removing the pontoons.

After the main girders were placed in position, it was necessary to remove the launching trollies from the rear ends, and transfer the ends of the girders to the pendulum suspension links. This was effected by 100-ton jacks, assisted by specially constructed rail-levers, as two jacks were not powerful enough to raise the end of one girder weighing 250 tons. To remove the trollies, the jacks were placed directly under the projecting ends of the pins G at the after ends of the trollies; by lifting these pins about 3 inches, the girder ends were raised half that amount, and hard-wood packings were inserted beneath the vertical side plates of the end boxes; these packings were armed with 5-inch by 1-inch bar-irons on the top to facilitate the sliding of the girder ends under variations of temperature. The after ends of the trollies being then lowered, the pins B were removed from the semicircular bearings at the ends of the girders, and the trollies hauled back clear of the girders. The transverse diaphragms, temporarily removed from the end boxes of the girders to make room for the trollies, were replaced and riveted; the weight of the girders was then taken at a point near the first cross girder on a platform of rails bedded in Portland cement outside, and clear of the cast-iron bed-plates, by the 100-ton jacks, assisted by rail-levers; and the packings under the sides of the end boxes having been removed, the saddle castings with pendulum links were slid into place on the bed-plates, and the pins B having been inserted through the holes in the lower ends of the links, the semicircular bearings of the ends of the girders were lowered on to them, and the saddle castings finally bolted down to the bed-plates of the abutments.

The difference in the length of the superstructure of the bridge between 40 degrees, the lowest temperature in the cold season, and 140 degrees, the maximum temperature in the sun in the hot season, allowing for portions of the girders not being exposed to the sun's rays, may amount to 6 inches; the bridge being fixed in the center, this is equal to 3 inches at each end. To provide for this, the joints of about a dozen 23-foot rails, adjacent to the bridge at each end, have a play of one-half inch each, and the fish bolts are regulated to admit of the rails traveling to that extent. The daily expansion and contraction due to variations of temperature do not exceed 1½ inch at each end of the bridge. The total steel weight of the superstructure is 3,876 tons.

The cost of the bridge, including the approach viaducts, was £261,178.

Land for the works was acquired and preliminary work begun in 1882, but the actual bridge construction was begun with the launch of the first caisson on the 2d of March, 1884, and completed with the suspension of the girders of the Naihati main span to the saddle castings on the 22d of December, 1886.

WORK has already been begun in changing the horse railroad in Broadway, New York, to a cable road. The contractor is John D. Crimmins, of New York. The cable conduits will be of steel plate with cast-iron yokes.

SLOW-BURNING CONSTRUCTION.

In a circular recently issued by the Boston Manufacturers' Mutual Fire Insurance Company the accompanying illustration is given, showing the section of a mill of the customary or standard type. Concerning it the following is taken from the circular:

Two floors are pictured, showing a section of the wall cut off at pilasters between the windows, the thickness of panels to be adjusted to the thickness designated in the drawing. If additional stories are required, the walls may be increased in thickness according to the number of stories added, after a computation of the loads which a standard factory may be called upon to sustain.

The window at the left represents what is known as the English type of window, such as it is customary to place in Great Britain in factories of four or five stories in height and not exceeding 126 feet in width, inside measurement—the lower sash being either fixed or swinging on hinges, the upper sash mounted like a transom, and opening inward for ventilation.

Attention is called to the rough plate, or what is now called "rolled cathedral glass," which is transulcent but not transparent, diffusing the light, making no hard shadows, and preventing the glare of sunlight to such an extent that window shades are seldom required.

It is assumed that no well-informed mill owner, engineer, or builder would fail to construct the stairways in towers or sections of the building, cut off by incombustible walls from all the rooms of the factory, the entrances to each room being guarded with standard fire-doors.

Elevators should either be placed in fire-proof shafts guarded by fire-doors and covered overhead by skylights, glazed with thin glass, protected underneath with wire netting; or else the hatchways in each floor should be well guarded by automatic or self-closing hatches.

In modern practice all belts or ropes which may be used for the transmission of power to the various rooms are also placed in incombustible, vertical belt chambers, from which the power is transmitted by shafts through the walls into the several rooms of the factory. There should be no unprotected or unguarded openings in the inner walls of this belt chamber. These belt chambers may also be covered in with skylights and netting in the manner prescribed for the fitting of the elevator well; the object in all cases being to provide an easy outlet for smoke, heat, and sparks, should a fire occur.

The most important feature in what is called slow-burning construction is to make each and every floor continuous, avoiding belt holes and open ways to the utmost possible extent, so that a fire originating in any one room may be confined to that room or story if possible.

In specially hazardous places ceilings may be protected by plastering of the ordinary kind laid on wire lathing nailed directly against the ceiling between the timbers. What is known as adamant plaster may also be applied directly against the plank without any intermediate space if put on to wooden laths cut in what is known as the "dove-tail" or "button" section. This plaster hardens immediately, and is not easily detached by the vibration of the machinery overhead.

Timbers, unless known to be absolutely and fully seasoned, should not be incased in any kind of air-proof plastering. They may be covered in with common lime mortar laid on wire lathing, provided no skim coat of lime putty is added. Ordinary plastering unskimmed is sufficiently porous to permit seasoning. As a rule timbers may be left unprotected, except in very dangerous places, since any fire which will seriously impair and destroy a heavy timber will already have done its work upon other parts of the structure.

In many instances it may be preferable to substitute compound beams for single timbers, made by securing two or more beams or thick planks side by side; it being often easier to obtain well-seasoned lumber in smaller dimensions; such compound beams, of which the parts may be slightly separated by spaces for ventilation when put together, are less subject to decay.

Weaving mills can be made more rigid and more capable of resisting the vibration caused by the motion of looms by laying the top floor across the plank and parallel to the beams, nails being driven in diagonal rows. This may brace the floor as firmly as diagonal boarding, and it avoids the increased expense in construction and repairs which ensues from the adoption of that method.

The edges of the floor plank should be kept clear of the faces of the brick walls by about half an inch in order to obviate the danger of cracking the walls, which sometimes occurs from the swelling of the plank when laid close against them. These cracks must be covered by strips or battens both above and below.

Asphalte paper may be substituted for asbestos paper between the top floor and the plank whenever the building acts will permit. The asphalte paper is considered a better material, as it is a retardent to the flow of water as well as to the passage of fire.

Basement floors can be laid solid upon the natural soil, if it is dry, or upon rock or cinder filling by covering either with a suitable layer of coal tar concrete. Upon this concrete place an under floor of 2-inch chestnut plank. Then lay the top flooring across the plank and nail in the usual manner. Sills under the plank are not thought to be necessary to the preservation of the floor. They may be called for to sustain machinery which requires to be bolted more firmly than it can be upon a plank and board floor; but in such cases independent foundations of masonry will generally be preferred. A basement floor laid in the manner described upon a coal-tar concrete has been in service 24 years in a machine shop, which is in a rather damp location on the banks of a river, and as yet there is no indication of decay. Cement concretes may absorb moisture and promote the decay of timber or plank laid upon them.
